[2] 1995 covered only two periods.

overall initiative and control of pack activities (Schenkel 1947; Mech 1970, 1999; Peterson et al. 2002).

I collected data over periods of 1-8 weeks from June through early August 1986-2005, except 1997, 1999, 2000, and 2001. Most of the longest data collection took place 1986-1996 (Table 1). Because study periods, pack behavior, and observation emphasis varied over the summers and years (Table 2), biases in the collection of urine-marking and ground-scratching data over both the total duration of the study and over the seasonal extent of the study each summer probably affected the data collected. Thus only the data on ratios of marking postures should be unbiased enough to warrant statistical testing, and I make no attempt to draw detailed conclusions from the untested data. However, these data are still useful to make broader conclusions and to establish several facts that heretofore were unknown or poorly documented in free-ranging Wolves during summer.

Results

I identified three breeding female and three breeding male Wolves, plus one pair without pups, that traveled, hunted and marked together (Mech 1995, 2005, and unpublished). I recorded males making 121 raised-leg urinations (RLU) 22 June – 8 August and 30 standing urinations (STU) 15 June – 10 August; and females, 47 flexed-leg urinations (FLU) 15 June – 3 August, and 70 squat urinations (SQU) 15 June – 29 July (Table 2). The proportion of male RLUs was significantly higher than the proportion of female FLUs ($\chi^2 = 45.01$; $P < 0.0001$; $d.f. = 1$). The number of both male and female marks I observed per weekly observation period appeared to decrease over the summer (Table 2). The number of recorded urinations per observation period varied by year from 1.3 to 7.2. (Table 1).

In addition to FLUs by breeding females, I also observed a pre-breeding female (bred the next year) FLU twice on 6 August. An associate had also seen this animal do "slight FLUs" three times on 13 July (see Discussion.)

I observed double marking (Rothman and Mech 1979) 24 times between 26 June and 3 August. Double marking is marking of a single location by both members of a mated pair within a few minutes of each other and can be initiated by either member. Of eight possible combinations of double-marking postures (RLUs or STUs initiated by males, FLUs or SQUs initiated by females) I observed five of the combinations, with those involving RLUs and FLUs significantly predominating (Table 3).

I observed ground-scratching by both male and female breeding Wolves or by either individual as early as 15 June and as late as 31 July. The pre-breeding female (above) scratched as late as 6 August. Besides the breeders' and pre-breeder's ground-scratching, a non-breeding female was observed scratching during two different summers, the same Wolf each year. Of 16 summers when I observed breeding or mated Wolves, I recorded no scratching by them during seven of those years and three or less scratching events during six other summers.

Only during 1992, 1993, and 1996 did I see Wolves do much scratching, and both male and female breeders did so. During the above years, the breeding pair I studied, the same individuals each year, scratched regularly. Those two individuals had also been the breeders since 1989, but I saw little scratching during 1989-1991, 1994 or 1995. During 1992, the breeding pair scratched (and urine-marked – Table 2) much more than I had seen them in the past. They scratched (and urine-marked) especially (1) near a Muskox they had killed and at which a non-pack Wolf had also been feeding a few minutes before, (2) near a garbage dump where at least one non-pack Wolf had been feeding regularly and (3) along the easternmost location (ter-

[1] Because of potential biases in times and methods of data collection, fine comparisons are not necessarily valid.

ritory boundary?) where we saw them that summer. During 1996, the breeding female scratched and urine-marked while trying to force a Muskox away from the den. In another study area, in the Canadian Northwest Territories, I also observed wolves scratching several times at a Red Fox (*Vulpes fulva*) den (Mech unpublished) during August.

I observed ground-scratching in various elimination contexts: (1) with no other marking behavior, (2) followed by FLU or RLU, (3) preceded by FLU, RLU or SQU, (4) preceded and followed by FLU, or (5) preceded by defecation, similar to the findings of Peters and Mech (1975) and Mertl-Millhollen et al. (1986).

I also observed urine-marking in relation to food remains as Harrington (1981) also did. Breeding males and females used all four kinds of urine postures in marking uneaten food remains or prey odors including the following (1) Arctic Hare intestines; (2) chewed bones; (3) Arctic Hare stomach contents; (4) locations where regurgitated or other food had recently been eaten; (5) old kills; (6) the head of a recent Muskox kill; (7) a putrid Muskox carcass which they sometimes fed on but often passed up; (8) where another Wolf had tried but failed to catch a lemming; and (9) at caches of which they or another Wolf (including a pup) had just consumed the contents.

TABLE 3. Order and type of urination postures in double urine marks[1] by arctic Wolves observed during summers 1986-2005 on Ellesmere Island, Nunavut, Canada. (Males do raised-leg [RLU] and standing [STU] urinations, and females, flexed-leg [FLU] and squat [SQU] urinations.)

SQU-STU	0

[1] Urination sequences involving RLUs or FLUs occurred significantly more often than expected by chance ($\chi^2 = 6.86$; $P = 0.03$; $d.f. = 1$).

Discussion

Captive breeding male and female Wolves urine-mark at all times of the year, with the peak frequency during the winter breeding season, and with all studies except that by Ryon and Brown (1990) observing that males tend to mark more year around than females (Peters and Mech 1975; Mertl-Millhollen et al. 1986; Asa et al. 1990; Barja and Miguel 2004).

Information on urine-marking frequencies during summer in captive wolves varies considerably. In one case, where the breeding pairs had pups, both males and females increased their marking rate during summer (Mertl-Millhollen et al. 1986). In another, where "reproductive pairs" were studied, but no pups were born, the males increased their rate of RLU during summer, but the females did not increase their FLU rate (Barja and Miguel 2004). In two others, where no pups were involved, the RLU and FLU rates of dominant males and females reached their minimum in summer (Asa et al. 1990; Ryon and Brown 1990). Testosterone tends to decrease to a minimum during summer (Asa et al. 1990), as does testis size (Mech 2006). This relationship suggests that urine-marking, which depends on testosterone (Asa et al. 1990), would also decrease then. However, the variations found in the studies cited above suggest that the social milieu can affect the relationship between testosterone and urine-marking, so that the relationship might not always be so tight, as Asa et al. (1990) also found. Because of possible biases mentioned earlier, my data can add little to this subject, although conceivably the extreme variation seen in my data reflect actual behavioral variation similar to that reported in captive Wolves. In that respect, my data on ground-scratching are instructive.

This study documents for the first time that wild Wolves urine-mark throughout summer, using all known urine postures, including double-marking, but

that the proportion of RLUs and FLUs to STUs and SQUs is lower then than in captive Wolves during winter (Asa et al. 1990) when RLUs and FLUs tend to predominate (Peters and Mech 1975).

The fact that a pre-breeding female was seen FLUing ("RLU" in Mech 1995) is of special interest. Based on my observation of this pack the previous three summers, I inferred that she had been born two years earlier. This pre-breeder began dominating the breeding female, her apparent mother, about the time the pre-breeder began FLUing. The pre-breeder bred the next year, apparently with her father, and remained bonded to him for the next six years, producing pups during four of them while the mother remained with the pack for two more years without being seen FLUing, and then disappeared (Mech 1995 and unpublished). This behavior of a young offspring starting to FLU or RLU and challenging its same-sex parent for dominance is similar to that seen in a captive colony (Asa et al. 1990).

Previous information about free-ranging Wolves ground-scratching in summer comes only from a single study which concluded that between April and September, ground-scratching was low and stable (Zub et al. 2003). I could make no similar seasonal comparison, but it was clear from my multi-summer observations that the degree of ground-scratching varied considerably from summer to summer, with no scratching seen some summers and regular scratching during others. In 1992, the year of most scratching, the presence of non-pack Wolves seemed to be the pertinent stimulus. It was the only year I observed the Wolves I had been studying chase or attack outsiders on three occasions (Mech 1993). It was also the year when I recorded the highest amount of urine-marking (Table 1), when the Wolves usually were extra alert and looking around intently when they marked and scratched, and when they marked their easternmost locations, suggesting a territory boundary. My impression during these times was that the Wolves were in a high state of arousal and aggressiveness. Both breeding males and females scratched about equally, contrary to Mertl-Millhollen et al. (1986) who found primarily females scratching.

Regarding marking of food remains, my observations confirm those of Harrington (1981) on captive Wolves and support his conclusion that marking of recently emptied food caches (and by extension from my observations, other inedible food remains) signals that a site contains no more edible food despite lingering odors.

In summary, this study documents that much information learned about Wolf urine-marking behavior in captivity during summer applies to free-ranging Wolves; it extends information about ground-scratching; and it places information from captive studies about urine-marking of food remains in its natural context.

Double Marking in Arctic Wolves, *Canis lupus arctos*: Influence of Order on Posture

FRED H. HARRINGTON

Department of Psychology, Mount Saint Vincent University, Halifax, Nova Scotia B3M 2J6 Canada

Harrington, F. H. 2006. Double marking in Arctic Wolves, *Canis lupus arctos*: Influence of order on posture. Canadian Field Naturalist 120(4): 471–473.

Double marking by Arctic Wolves (*Canis lupus arctos*) was recorded by Mech (2006) from a pack on Ellesmere Island, Nunavut, Canada, during 16 summers between 1986 and 2005. Using his data on the frequency of occurrence for each of the four postures used by Wolves for urine marking (males – raised leg and stand urinations; females – flexed leg and squat urinations), the probabilities of occurrence for each of eight possible double mark sequences were determined and compared with observed frequencies. Females were somewhat but not significantly more likely to initiate double mark sequences. There was no evidence for any bias in the posture used to initiate a double mark sequence, but assertive postures by both males and females nearly always completed the sequence, occurring much more often than expected by chance.

Key Words: Arctic Wolves, *Canis lupus arctos*, scent-marking, double marking, pair bonding, mate guarding, urine-marking, Ellesmere Island, Nunavut, Canada.

Double marking, in which a mated pair urine marks a single site in quick succession, is commonly observed in Wolves (*Canis lupus*) (Harrington and Asa 2003), although evidence from wild Wolves is often inferred from the pattern of urine marks on snow (Peters and Mech 1975; Rothman and Mech 1979). Direct observations, such as those of Mech (2006), permit the identification of the postures used in marking, from which underlying motivation might be inferred. Males may use either raised-leg urinations (RLUs) or standing urinations (STUs) and females either flexed-leg urinations (FLUs) or squat urinations (SQUs), with the former posture for either sex considered to be more reflective of aggressive or assertive motivation (reviewed by Harrington and Asa 2003). Thus there are eight possible forms that a double marking sequence can take. Mech (2006) has presented data on urine-marking in Wolves, recorded by direct observation from Arctic Wolves, *Canis lupus actus*, during the summer. Among those data are 24 cases of double marking (Table 1), and the reported finding that the more assertive postures (RLUs and FLUs) occur more frequently in double marking. The purpose of this note is to extend the analysis of those data in order to offer more insight into the motivation behind double marking.

TABLE 1. Urination postures used during double marking by Arctic Wolves during summers 1986-2005 on Ellesmere Island, Nunavut, Canada. Male postures: raised-leg [RLU] and standing [STU] urinations; female postures: flexed-leg [FLU] and squat [SQU] urinations. (Data from Mech 2006).

SQU-STU	0

Methods

A dominant adult Wolf may urine-mark using either posture appropriate for its sex. This analysis seeks to determine whether there is a non-random pattern in the use of either posture, by either sex, in double marking compared to urine-marking in general. Therefore I first determined the overall frequency of each urination posture that occurred exclusive of double marking (Table 2) to yield two base rates, one for the probability of occurrence for each of the postures overall and another for the probability of the occurrence of each form within a sex. From these probabilities, one can calculate expected frequencies for each form of double mark, under the assumption that the postures used in double marking simply represent random combinations of the postures utilized otherwise. This is done by multiplying the value from row 1 (the random probability the posture will occur overall and thus initiate a sequence) with the value from row 2 (the random probability the other sex will use one of its two alternative postures to complete the double mark). Thus, for example, the

TABLE 2. Calculation of the probability of occurrence for each of the urination postures used by Arctic Wolves on Ellesmere Island, Nunavut, Canada during summers 1986-2005.

	Urination posture				
	RLU	STU	FLU	SQU	Total marks
Total marks	121	30	47	70	268
Minus double marks	-22	-2	-17	-7	-48
Non-double mark urinations	99	28	30	63	220
(1) Probability of posture (overall)	0.45	0.13	0.14	0.28	1.00
(2) Probability of posture (within sex)	0.78	0.22	0.32	0.68	1.00/sex

TABLE 3. Expected and observed frequencies of occurrence for each of the eight different forms of Wolf double marking, for Arctic Wolves on Ellesmere Island, Nunavut, Canada during summers 1986-2005. Expected frequencies are based on the combined probability of occurrence for each posture in the sequence (from data in Table 2), under the assumption of independence of occurrence for each posture type and based on a sample size of 24.

	Double urination mark sequence			
Male initiated sequences	RLU-FLU	RLU-SQU	STU-FLU	STU-SQU
Expected frequency	3.5	7.3	1.0	2.1
Observed frequency	6	1	2	0
Probability of occurrence	0.144	0.306	0.042	0.088
Female initiated sequences	FLU-RLU	FLU-STU	SQU-RLU	SQU-STU
Expected frequency	2.6	0.7	5.2	1.5
Observed frequency	9	0	6	0
Probability of occurrence	0.109	0.031	0.218	0.062

probability for an RLU/SQU double mark to occur at random is 0.45•0.68=0.306, whereas a double mark in the reverse order (SQU/ RLU) is expected less often (0.28•0.78=0.218), primarily because males are more likely to use dominant postures overall than are females (Table 3).

Results

Three questions can be addressed using the probabilities generated in Table 3. First, is one sex more likely to initiate a double marking sequence? Although females initiated 63% of the double marks observed, compared to the expected frequency of 42%, this increase was not greater than expected by chance ($\chi^2 = 2.10$, df = 1, ns). Second, is the first mark more likely to be from an assertive posture than otherwise? Again, although twice as many double marks were initiated using the more assertive RLU and FLU postures, this was expected overall, given the high rate of assertive posturing (59%) among dominant Wolves ($\chi^2 = 0.322$, df = 1, ns). Finally, is the second mark which completes the double mark, more likely to be from an assertive posture? Here, the data indicate a highly significant deviation from expectations ($\chi^2 = 13.90$, df = 1, $P < 0.001$). All but one of the second marks involved either RLU or FLU postures. The one exception was an RLU by the male followed by a SQU by the female. Males increased their use of RLUs from a base rate of 78% in other situations to 100% when completing a double mark, while females increased their use of FLU postures even more dramatically, from 32% overall to 89% in double marks.

Discussion

Several captive studies have found that dominant female Wolves are usually the initiators of double marks (93% of double marks, n=23, Rothman and Mech 1979; 64%, n=36, Mertl-Millhollen et al. 1986). In a sample of over 700 double marks by free-ranging Coyotes (*Canis latrans*), Gese and Ruff (1997) found that double marking was initiated by females 75% of the time. Unfortunately, none of the previous studies tested observed initiation rates against expected rates, based on the overall frequency of marking by individuals of each sex, as I have done here. However, the females observed by Mech (2006) did initiate double marking more often than expected, at a rate (63%) comparable to previous studies, so the lack of statistical significance for this result may be an artifact of small sample size. Thus it seems likely that double marks are more likely to begin as urinations by dominant females.

Mertl-Millhollen et al. (1986) found that 94% of double marks in their captive pack were initiated by RLUs (they combined RLUs and FLUs in their analyses). Unfortunately, although they indicate that RLUs comprised the majority of the marks they recorded, they do not present their data in a manner to allow testing of expected versus observed rates for the postures. In the present study, although the initial posture used in a double mark was most often an

assertive one (RLU or FLU), this is to be expected, given the relatively high rate of these postures in dominant individuals. This analysis suggests that the initial mark of a double mark occurs as an independent event, influenced by a combination of internal factors (arousal, hormones, urine load, etc.) and features of the environment (smells of old marks, food odors, conspicuous visual objects, etc.), but not with the deliberate intent to initiate a double mark sequence. For example, when Wolves are traveling, the lead Wolf is typically the initiator of double marks (Mech 1999); as it encounters sites which elicit its marking, the opportunity for double marking is then created for the trailing Wolf.

The second mark, however, is highly influenced by the presence of the first, and either its freshness, individual identity, chemical composition, or its mere presence at a specific location induces the second individual to use the more assertive RLU or FLU posture. Mertl-Millhollen et al. (1986) likewise found that all but one second mark was either an RLU or FLU; the one exception was a SQU (they combined SQUs and STUs) that followed another SQU. Thus the second mark of a double mark likely represents an increased level of arousal on the part of the marker. Whether that arousal represents generalized excitement, increased sexual motivation or increased aggressive (protective) motivation is not possible to determine here. A variety of hypotheses have been advanced to account for double marking: pair bonding, reproductive synchronization, mate guarding, and territorial defense being among the most common (Rothman and Mech 1979; Mertl-Millhollen et al. 1986; Gese and Ruff 1997). The tight relationship between the frequency of double marking and successful reproduction in Wolves (Rothman and Mech 1979; Asa et al. 1986; Mertl-Millhollen et al. 1986; Peterson et al. 2002) suggests that mating related functions, including mate guarding by the male, are most likely.

Acknowledgments

This note grew out of a manuscript review. I would like to thank L. D. Mech and F. R. Cook for the invitation to prepare this paper and for their willingness to expedite its consideration. I also thank my students for their patience in receiving their final grades while I worked on the manuscript.

Use of "Micro"-Corridors by Eastern Coyotes, *Canis latrans*, in a Heavily Urbanized Area: Implications for Ecosystem Management

JONATHAN G. WAY[1] and DAVID L. EATOUGH[2]

[1]Biology Department, Boston College, Higgins Hall, Chestnut Hill, Massachusetts 02467 USA. e-mail: jw9802@yahoo.com. Present address: 64 Cranberry Ridge Road, Marstons Mills, Massachusetts 02648 USA.

Way, Jonathan G., and David L. Eatough. 2006. Use of "micro"-corridors by eastern Coyotes, *Canis latrans*, in a heavily urbanized area: implications for ecosystem management. Canadian Field-Naturalist 120(4): 474-476.

We document the use of very narrow, linear corridors (termed "micro-corridors") that facilitated movements by both a transient and a resident group of eastern Coyotes (*Canis latrans*) in a heavily urbanized area in north Boston, Massachusetts. Two corridors are discussed: one, a railroad line through downtown Boston; and two, a hole in a cemetery fence giving access to two separated cemeteries in a region of intense human development. Coyotes can be good subjects to illustrate the use of fragmented landscapes because they are common and thus are abundant enough to study yet are wary and avoid novel things and generally avoid people.

Key Words: Eastern Coyote, *Canis latrans*, corridor, fragmentation, Massachusetts, micro-corridor, urbanization.

The use of corridors is becoming increasingly recognized as an important conservation tool in fragmented landscapes (Beier 1995; Gilbert et al. 1998; Meffe and Carroll 1994). Corridors are strips of habitat connecting otherwise isolated habitat patches and have been promoted as important features of reserve design that allow movement among high(er) quality habitats (Meffe and Carroll 1994). Connecting landscapes rather than maintaining a large unfragmented core ecosystem is becoming the only alternative in many urbanized areas, especially where unregulated sprawl is occurring (e.g., Beier 1995). Yet, there is a paucity of data on animal use of corridors and how effective they are in connecting landscapes (Gilbert et al. 1998; Meffe and Carroll 1994). Because of the natural history of predators (e.g., large territories, long-distance movements), a knowledge of carnivore biology can predict minimum areas where ecosystems can function relatively naturally (Beier 1993; Gittleman et al. 2001; Mech and Boitani 2003; Meffe and Carroll 1994; Way et al. 2002a). However, the effectiveness (positive or negative) of corridors could greatly affect the size needed to maintain predators in certain sized refuges.

Coyotes are common in North America (Parker 1995), yet are elusive and difficult to capture (Way et al. 2002b); they are known to avoid novel objects and structures that are dangerous to them, such as box traps (Way et al. 2002b) or foothold traps (Conner et al. 1998; Sacks et al. 1999). Because Coyotes are ubiquitous (Parker 1995), neophobic and wary (Sequin et al. 2003), and have relatively large home ranges and movement rates (Way et al. 2004), they are a good species to use in the determination of corridor use, especially in urban areas. In other words, although they are common and frequently use human-dominated areas (Grinder and Krausman 2001; Way et al. 2004), they are naturally shy and avoid people by being nocturnal and traveling quickly in and out of human-dominated areas. For example, Way et al. (2004) found that Coyotes travel extensive distances on linear pathways such as powerlines, railroad tracks and golf courses in urbanized areas of Cape Cod, Massachusetts. Findings of Coyote use of corridors in highly urbanized and fragmented areas can potentially be used by managers to help protect more rare species and/or better design reserves for more common species. In this note, we describe the use of very narrow, linear (also called line corridors by Meffe and Carroll 1994) "micro"-corridors.

Study Area and Methods

Coyotes were captured for an ecological study on the north edge of Boston (42.43°N, 71.06°W), in eastern Massachusetts, in the bordering cities of Everett (4345.0 people/km^2), Malden (4290.5 people/km^2), and Revere (3089.0 people/km^2) (U.S. Census Bureau, 2000 estimates). Coyotes were captured by box trap (Way et al. 2002a) or by ground-based netlauncher (one coyote; Coda Enterprises, Mesa, Arizona) and outfitted with radio-collars (Mod-400, Telonics, Mesa, Arizona, USA and M1900, Advanced Telemetry Systems, Isanti, Minnesota, USA). Tracking protocols were described by Way et al. (2002a) and Way et al. (2004). Portable receivers (Custom Electronics, Urbana, Illinois, USA) and hand-held 3-element Yagi antennas were used to radio-track Coyotes both on foot and from a vehicle. Because of the highly developed landscape with many roads we mostly restricted our activities to automobiles as Coyotes did not react to them as much as to people (e.g., by running away; J. Way, unpublished data); occasionally we approached radio-collared Coyotes as close as possible on foot without disturbing them. We used binoculars and video-cameras when observing Coyotes, and city street lights, nightscopes, and occasionally headlights when following Coyotes at night with a vehicle (Way et al. 2002a; Way et al. 2004).

Observations

On 13 April 2004 we box-trap captured a dispersing 13.6 kg female Coyote ("Fog" – ID #BN0402) in a wooded section of Revere. Based on her behavior, she seemed to have been dispersing from the north to the south when she reached our study area. Her movements the week after capture were mostly to the south, including traveling >1 km through densely populated neighborhoods and streets. She localized in four different areas for 2-3 days each before moving to a new location. On 26 April 2004 we located her in a fenced-in abandoned field of ca. 4 ha behind a shopping mall at the north edge of the city limits of Boston. She reached that location by either swimming a 200 m river or traveling along railroad tracks over that same river. Based on data taken earlier that night we suspect that she went on the railroad tracks. For 3 days she remained in the fenced-in area and ate many Norway Rats (*Rattus norvegicus*) and Cottontail Rabbits (*Sylvilagus floridanus*) (J. Way, unpublished data).

On the night of 29 April she traveled 1.8 km southwest on the railroad line (which was bordered by industrial buildings on both sides), going under Interstate 93 and the Zakim Bridge, and entered an abandoned railroad yard in Boston where she spent the following day in a sparsely vegetated 200 × 50 m area. At 02:00 h on 30 April she followed the railroad tracks west through the Cambridge part of Boston and found the first wooded area available 4.9 km from her previous day's location. She was inactive through 23:37 h on 30 April 2004 and could not be located until 19 November 2004 when she was found alive 100.5 km south of her capture location (and 88.9 km south of her last location in Cambridge) in the town of Dartmouth, Massachusetts, near the Rhode Island border. To make that voyage Fog had to have crossed (over or under) six major interstate highways, including route 93 described above.

From 17 May 2004 to 3 April 2005 we monitored a pack of Coyotes ("The Cemetery Pack") in the bordering towns of Everett, Malden, and Revere. Four Coyotes were captured and radio-collared in this pack: one, "Maeve" (#BN0404), a 14.5 kg lactating female, captured 17 May 2004, was the breeding female; two, "Jet" (#BN0403), a 15.9 kg breeding male, captured by netlauncher on 29 June 2004, was Maeve's mate; three, "Jem" (#BN0406), a 10.0 kg 4.5-month-old pup, was captured on 26 August 2004; and four, "Cour" (#BN0405), a 12.3 kg 5-month-old pup, was captured on 15 September 2004. The pack consisted of two to three adults (i.e., one additional uncollared coyote was occasionally sighted in the pack's territory – its status was never determined but it was probably a helper Coyote [Way et al. 2002a] to Jet and Maeve) and four pups (two of which were not collared). The group went from six to seven members to four individuals by mid-winter 2004-2005 when it was presumed that some of the pack members (two of the pups [including Jem, last successfully located on 11 December 2004] and probably the uncollared adult) dispersed. The group resided almost exclusively in a green area (including some thicker woods) surrounding four large connected cemeteries. The entire area was about 2.5 km^2 (J. Way, unpublished data) and aside from inactive railroad tracks (i.e., no trains used them) the pack's territory was surrounded by high-density housing units and/or commercial spaces (malls) on all sides. Two roads transected their range, including a straight east–west road (Fuller Street) in the central part of their territory that connected the two cemeteries that they most frequently used.

Most of the cemeteries were surrounded by fencing consisting of vertical metal bars spaced 10 cm apart. The narrowness of this space prevented the Coyotes from crossing through the fence at random locations. However, a small corridor connected two cemeteries where a 34 cm opening occurred at a height of 55 cm in the south cemetery because of a missing metal post and two bent poles, one on each side. After crossing Fuller Street diagonally for about 15 m the Coyotes could then go through an open 305 cm × 198 cm gate (this door was never shut) followed by six steps that lead down into the north cemetery. Besides that crossing, there were two roads (one open to cars, the other gated) approximately 50 m east of the main corridor that the Coyotes could use (by diagonally crossing Fuller Street) to access either cemetery. There was one other opening (< 20 cm) in the south cemetery fence about 400 m west of the main corridor that led into a residential neighborhood (after crossing Fuller Street) bordering the west part of the north cemetery. Cour was the only coyote to use the road crossing corridor regularly and Maeve was the only one observed to use the neighborhood crossing corridor.

We radio-tracked the Coyotes six to seven days per week on average and, when tracking them at night (street lights illuminating the area), usually made sightings (range: one to ten sightings per night) from our parked, turned off vehicle of one to five Coyotes together crossing the main corridor (exceptions were during a heavy snowstorm [ca. 60 cm] when they did not use the south cemetery at all). They often also crossed the road in daylight during the early morning (06:00-08:00). During their first 6 months (i.e., April to October) sightings included some of the pups going under the fence (17 cm from fence to dirt) about 1 m west of the opening in the fence leading to the south cemetery, often during the same crossing (i.e., they were together) as other Coyotes went through the opening in the fence. This section of Fuller Street was straight, thus the Coyotes could see in both locations and we often watched them, especially the adults, standing on a hill in the south cemetery watching traffic and crossing when there were not any cars going by. Except for two instances when the Coyotes were almost hit by cars (the cars had to brake) all crossings were successful.

Monitoring of this group ended after the non-dispersing members (Maeve, Jet, Cour and one uncollared) were illegally poisoned.

Discussion

These data indicate that very small areas, if positioned in the right place, can be very important for Coyotes. These micro-corridors gave access to city habitats with few to no trees (along the railroad tracks) and also connected fragmented areas (cemeteries with fences) in already very urban landscapes. While not ideal habitat for Coyotes, these corridors were certainly better than nothing, and echoing the statement of Beier (1995: 235) when discussing Cougar (*Puma concolor*) dispersal, "any connection between two isolated patches is better than no connection." Managers can use these data for ≥3 purposes: one, to provide better habitat connectivity in already fragmented landscapes (e.g., opening sections of fence where wildlife is likely to cross); two, proactively establishing these types of corridors (ideally larger than described in this paper) where development is planned; and three, more regional planning where important habitat exists and maintaining linkages between separated core habitats.

The importance of sub-marginal habitats can not be overstated to facilitate animal movement. For example, Beier (1995) noted that Cougars can use corridors 100 m wide if the distance is < 800 m and 400 m wide if 1-7 km, yet adult Cougars have enormous home ranges in the hundreds of km^2 (Beier 1993, 1995). Likewise, species previously thought to inhabit only wilderness such as Wolves (*Canis lupus*) can often live at least at the edge of human-dominated areas if not persecuted (Mech and Boitani 2003) and no doubt corridors facilitate travel in and out of these landscapes. While preserving larger areas (e.g., Beier 1995) is preferred, this is not always possible in the real world and it is increasingly being discovered that animals are adaptable and can often respond to human-induced changes (e.g., Mech and Boitani 2003). Therefore, it is imperative to at least link what is remaining of our wild lands and this can start at the very specific micro-corridor landscape scale. For example, bridges that exist because of waterways (common in many cities) could also promote wildlife movement if cover and some space are provided.

Bald Eagle, *Haliaeetus leucocephalus*, Preying on Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, on Cape Breton Island, Nova Scotia

STORRS L. OLSON

Division of Birds, National Museum of Natural History, Smithsonian Institution, Washington, D.C. 20560 USA

Olson, Storrs L. 2006. Bald Eagle, *Haliaeetus leucocephalus*, preying on Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, on Cape Breton Island, Nova Scotia. Canadian Field-Naturalist 120(4): 477.

At 1053 hours on 23 July 2006 a Bald Eagle, *Haliaeetus leucocephalus*, was observed in flight transporting in its talons a live Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, at South Harbour (46°52'01.7"N, 60°26'45.8"W), Cape Breton Island, Victoria County, Nova Scotia.

Key Words: Bald Eagle, *Haliaeetus leucocephalus*, predator, Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, South Harbour, Cape Breton Island, Nova Scotia.

The Bald Eagle, *Haliaeetus leucocephalus*, is a large North American raptor that usually frequents aquatic environments where it feeds predominantly on captured or scavenged fish. Eagles may be seen daily in South Harbour, at the northern end of Cape Breton, Nova Scotia. This area appears to be occupied by a resident pair based on an observation of two adults seen standing very close together on a mud flat at the mouth of the harbour on 16 July 2006. South Harbour is a shallow, brackish, nearly landlocked estuary with an artificially maintained channel through the sandbar across its mouth providing exchange of water with the Atlantic Ocean.

On 23 July 2006 at 10:53 h, the screams of eagles drew my attention to two adult birds wheeling and skirmishing in the air over the southern shore of the harbour (46°52'01.7"N, 60°26'45.8"W). When two birds eventually flew directly overhead I saw that the lead bird was carrying a snake in its talons. The grayish-brown coloration and very attenuated, pointed tail writhing in characteristic ophidian fashion precluded any possibility of the prey being an American Eel (*Anguilla rostrata*). Two other witnesses (Johanna R. Humphrey, Katherine Allen) also confirmed that the prey, which was very much alive, was a snake. The individual carried by the eagle appeared to be somewhat in excess of 600 mm in total length. The only snake of this size in Nova Scotia would be a Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, females of which range from 412 to 916.9 mm, whereas males do not exceed 602 mm (Gilhen 1984). Because most of the area surrounding South Harbour, especially the southern shore, where the observation was made, is very heavily vegetated, the eagle most likely captured the snake while the latter was swimming across the surface of the water. Maritime Garter Snakes are "excellent swimmers" and have been seen on "freshwater lakes 100 metres or more from shore" (Gilhen 1984: 132).

The Bald Eagle feeds almost exclusively on vertebrates, paticularly on fish, followed by birds, and then mammals (Stalmaster 1987; Buehler 2000). Although Stalmaster (1987: 93) emphasized the eagle's "vast diversity of prey", he considered that snakes "are an unusual dietary item" (pages 95-96) and cited only the report of McEwan and Hirth (1980) of the remains of a single Black Swamp Snake, *Seminatrix pygaea*, in a nest in central Florida. Bald Eagles are notorious scavengers, and large numbers of snakes, including *Seminatrix*, are victims of vehicular traffic in central Florida (Smith and Dodd 2003), so there is a strong possibility that that food item was obtained as road kill. I have found no other references to Bald Eagles feeding on snakes, although they probably do so opportunistically wherever snakes and eagles occur together.

Rat Poison Kills a Pack of Eastern Coyotes, *Canis latrans,* in an Urban Area

JONATHAN G. WAY[1], STEPHEN M. CIFUNI[2], DAVID L. EATOUGH[3], and ERIC G. STRAUSS[4]

[1]Environmental Studies Program and Lynch School of Education, Boston College, Higgins Hall, Chestnut Hill, Massachusetts 02467 USA; e-mail: jw9802@yahoo.com Present address: Eastern Coyote Research, 64 Cranberry Ridge Road, Marston Mills, Massachusetts 02648 USA

Way, Jonathan G., Stephen M. Cifuni, David L. Eatough, and Eric G. Strauss. 2006. Rat poison kills a pack of eastern Coyotes, *Canis latrans*, in an urban area. Canadian Field-Naturalist 120(4): 478–480.

We document the death of a pack of Eastern Coyotes (*Canis latrans*) from high levels of brodifacoum, a second generation poison that is the active ingredient in some forms of rat poison (e.g., d-Con®). The Coyotes died within a week of each other during late March/early April 2005. This incident indicates the vulnerability of wild animals to commercial over-the-counter rodenticides.

Key Words: *Canis latrans* var., Eastern Coyote, anticoagulant, brodifacoum, poison, rat poison, Massachusetts.

Coyotes (*Canis latrans*) live successfully in a variety of habitats ranging from rural to urbanized areas (Gese et al. 1996; Harrison et al. 1991; Patterson and Messier 2001; Riley et al. 2003; Way et al. 2001, 2004). However, in almost all of these settings (except national parks; Gese et al. 1996) people constitute the major source of mortality for Coyotes usually via trapping, shooting and automobile strikes (Grinder and Krausman 2001; Parker 1995). Poison was historically used to kill predators but was banned in 1973 in the United States (Mech 2000; Mech and Boitani 2003). Mech (1970) noted that "poison is no doubt the most effective and efficient method of controlling or exterminating Wolves (*Canis lupus*)." However, the use of poisons is controversial because of their relative non-selectivity and reputation for inhumaneness (Cluff and Murray 1995). Most poisons, such as strychnine, cyanide, and sodium fluoroacetate (compound 1080), are not readily obtainable today. Because these poisons are illegal, many canid populations have greatly increased in the past 30 years (Mech and Boitani 2003; Parker 1995). Anticoagulants are present in urban areas (for rat control), and Riley et al. (2003) found them to be a significant cause of death for Coyotes in southern California. This paper details the poisoning deaths of a family group of Coyotes in urban north Boston, Massachusetts, most likely deliberately poisoned by someone .

Study Area and Methods

Coyotes were captured for an ecological study on the north edge of Boston (42.43°N, 71.06°W), in eastern Massachusetts, in the bordering cities of Everett (4345.0 people/km^2), Malden (4290.5 people/km^2), and Revere (3089.0 people/km^2) (U.S. Census Bureau, 2000 estimates). Box traps were used to capture Coyotes (Way et al. 2002a) except for one ("Jet") captured via a ground-based netlauncher (Coda Enterprises, Inc., Mesa, Arizona). Four Coyotes were radio-collared in this pack: "Maeve" (#BN0404), a 14.5 kg lactating female, captured 17 May 2004, was the breeding female; "Jet" (#BN0403), a 15.9 kg breeding male, captured 29 June 2004, was Maeve's mate; "Jem" (#BN0406), a 10.0 kg 4.5 month-old pup, was captured on 26 August 2004; and "Cour" (BN0405), a 12.3 kg 5 month-old pup, was captured on 15 September. The behavior of Maeve and Jet (i.e., frequently being located with each other and with the pups, including observations of them feeding the pups) indicated that they were the parents of these pups (see Way et al. 2001). The Coyote pack consisted of two to three adults (i.e., one additional uncollared Coyote occasionally sighted in the pack's territory – its status was never determined but it was probably a helper Coyote [see Way et al. 2002b] to Jet and Maeve) and four pups (two of which were not collared). The group was named the Cemetery Pack as it resided almost exclusively at one green area (including some thicker adjacent woods) surrounding four large connected cemeteries. The entire area was about 2.5 km^2 and on the north side, aside from unused railroad tracks the pack's territory was surrounded by high-density housing units and/or commercial spaces (malls) on all sides.

Results and Discussion

The group went from six or seven members in the fall of 2004 to four individuals by mid-winter 2004-2005 when it was presumed that some of the pack members (two of the pups [including Jem] and probably the uncollared adult) dispersed. Jem was last successfully located on 11 December 2004. Snow tracking and sighting data indicate that only one uncollared Coyote (a light yellowish-brown animal) remained along with the breeding pair and Cour. Similarly, Way et al. (2002b) found three to four individuals to be a

typical winter pack size of Coyotes in eastern Massachusetts.

The winter of 2004-2005 was harsh with much snow yet the Coyotes remained in their small territory. Residents often reported to us that they fed the Coyotes and people noticed some of the animals were collared (J. Way, unpublished data), indicating that the group obtained food from people living in and/or around the cemeteries. Aside from their abnormally small home range (see Way et al. 2002b), they behaved much like Coyotes studied in other locations, including the avoidance of people by being nocturnal (Way et al. 2004), crossing streets quite often, denning in wooded or relatively undisturbed (including under a gravestone) regions of their territory (Way et al. 2001), and acting territorial (Way et al. 2002b), including observations of Jet scent marking on the railroad tracks at the north edge of his pack's home range. There was no sign of the Coyotes' ill-health until just prior to them dying.

On 27 March 2005 Maeve was found dead in the middle of a cemetery in the central part of the pack's territory. She was an emaciated 12.7 kg despite appearing normal when sighted on 24 March. A gross necropsy revealed significant internal bleeding and no fetuses, indicating that she was not pregnant. A laboratory (Idexx Veterinary Services, www.vetconnect.com) diagnosis indicated erosive acute gastritis, severe necrotizing hemorrhagic endometritis with retained placental decidual tissue, and subacute suppurative endocarditis and myocarditis.

On 31 March 2005 Jet was found dead, 100 m from where Maeve died, and was also emaciated (14.3 kg). Radio-telemetry data indicates date of death was 30 March. He was observed moving normally 2-3 days before his death. Because of massive internal bleeding and similar gross necropsy results as Maeve, we only tested for poisoning (specifically for common chemicals found in household rat poisons) on Jet. Brodifacoum was detected in the liver at 0.733 parts per million (ppm), and the laboratory (Idexx) indicated that the results supported a diagnosis of brodifacoum poisoning.

On 3 April 2005 Cour was found dead in a shallow (< 1 m deep) canal that he frequently (i.e., daily) crossed prior to his death. He appeared healthy and weighed 17.3 kg, heavier than both of his parents. His relatively robust physique support observations from residents indicated that Cour (with a red ear tag) was the radio-collared Coyote most commonly seen eating food left by people. He was previously observed up-close and, besides limping on his right hind leg, appeared healthy on 1 April 2005. Not having obtained the results from Jet or Maeve at the time, we had a full necropsy performed at Tufts University (Grafton, Massachusetts). Internal bleeding (subcutaneous hemorrhage) was noted and based on autopsy findings and toxicological analysis of the liver (brodifacoum = 0.542 ppm), Cour died from an anticoagulant rodenticide. Because of the way Jet and Cour died, and the similar necropsy findings from Maeve (i.e., massive internal bleeding), we conclude that Maeve also died from brodifacoum poisoning.

Because all three of the Coyotes' behavior seemed normal prior to their death and that they all died close together (< 1 week), it appears that someone purposefully poisoned them at high concentrations rather than the coyotes having eaten enough poisoned prey to have died (i.e., from bioaccumulation; Riley et al. 2003). Most likely Maeve and Jet were poisoned around the same time, and then Cour was given a later dose(s) judging by a sighting of him traveling alone after Maeve and Jet were documented as dead. However, Cour's healthier condition might have allowed him to survive longer than his parents. We extensively searched for the source of the poisons (especially near where the coyotes died and where they spent the majority of their time when they were alive), including informally talking to numerous people, but we never managed to locate any substantial leads.

Throughout summer 2005 only a couple of sightings were made by residents and cemetery staff indicating that either the uncollared Coyote survived or, more likely, a new Coyote (i.e., formerly not part of this pack) dispersed into this location. Regardless of those individual sightings, this pack was decimated in a short period of time via rodenticides.

The public should be better informed of the dangers that common household poisons present for wildlife, especially in urbanized areas, and the potential health threat to humans and pets. For example, about two months later, pet dogs (*Canis familiaris*) died or were injured from rat poison in neighboring towns (S. Cifuni, personal communication). The slow, painful death of an animal internally bleeding is not pleasant and should not be acceptable in our society. These animals were diagnosed because they were part of an ecological study; due to the expense of testing and difficulty of finding non-radio-collared animals that die in the woods, it would be difficult to estimate how many non-target (i.e., not rats or mice) animals die from anticoagulants. We recommend that these poisons be strictly controlled either through making the over the counter sale of them illegal to all but licensed, professional exterminators and/or through required public education campaigns explaining the dangers of these poisons.

Acknowledgments

This study would not be possible without the support of the Way and Cifuni families, N. Lima, the Saugus Animal Hospital and Dr. Bob Binder, Fiore's Meat Market and The Meat Market (in Winthrop), D-L. Szumylo, the Environmental Studies Program and Urban Ecology Institute at Boston College. Numerous private individuals donated to have the necropsies performed and numerous residents in the area of the poisonings helped out in myriad ways. Care and

capture of free-ranging Coyotes was approved by Boston College's Institutional Animal Care and Use Committee Protocol Number 01-02 (renewed in 2005) and by the Massachusetts Division of Fisheries and Wildlife permit #003.04LP.

A New Record of Deepwater Sculpin, *Myoxocephalus thompsonii,* in Northeastern Alberta

M. STEINHILBER[1] and D. A. NEELY[2]

[1]Royal Alberta Museum, 12845 102nd Avenue, Edmonton, Alberta T5N 0M6
[2]Department of Biology, St. Louis University, St. Louis, Missouri 63103 USA
Corresponding author: e-mail: dave.neely@gmail.com. Present address: Department of Ichthyology, California Academy of Sciences, 875 Howard Street, San Francisco, California 94103 USA

Steinhilber, M., and D. A. Neely. 2006. A new record of Deepwater Sculpin, *Myoxocephalus thompsonii,* in northeastern Alberta. Canadian Field-Naturalist 120(4): 480–482.

We present the first documented records of Deepwater Sculpin, *Myoxocephalus thompsonii*, from northern Alberta, and the second record for the province. Three specimens of Deepwater Sculpin were taken in gill nets set at 17 to 20 m depth in Colin Lake, Alberta, on 15 September 2001. Colin Lake, located in the Canadian Shield region of northeastern Alberta about 125 km northeast of Fort Chipewyan, drains into Lake Athabasca via the Colin River. The only other known Alberta population of Deepwater Sculpin inhabits Upper Waterton Lake in the southwestern corner of the province. This record is approximately 300 km SSE of the nearest verified record in the Northwest Territories and 400 km NW of the nearest verified record in Saskatchewan.

Key Words: Deepwater Sculpin, *Myoxocephalus thompsonii*, distribution, Colin Lake, Alberta

Three individuals of Deepwater Sculpin, *Myoxocephalus thompsonii*, were collected in two separate gill net sets in Colin Lake, Alberta (59°34'N, 110°08'W) on 15 September 2001. One set was in 17 m of water, and fished for a period of 15 hours. The other was set at 18-20 m depth for 14 hours. Each net set consisted of one 60 m multi-mesh net with six 10 m panels ranging from 10 to 25 mm bar mesh and one 60 m net with six 10 m panels of 10 to 50 mm bar mesh. All nets were 1.8 m in depth. The two nets were fished in series on the bottom of the lake. Both collecting sites were located on the gently sloping periphery of the two deep basins in the lake (Figure 1). The maximum depth of the lake is approximately 25 m. The composition of the substrate at the sampling sites was not determined.

Species taken syntopically with the sculpins included Lake Whitefish (*Coregonus clupeaformis*), Cisco (*Coregonus artedi*), Burbot (*Lota lota*), Northern Pike

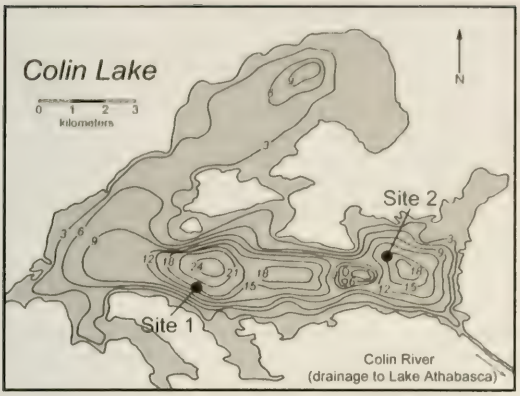

FIGURE 1. Bathymetric map of Colin Lake, with Deepwater Sculpin capture localities indicated. Depths given in metres.

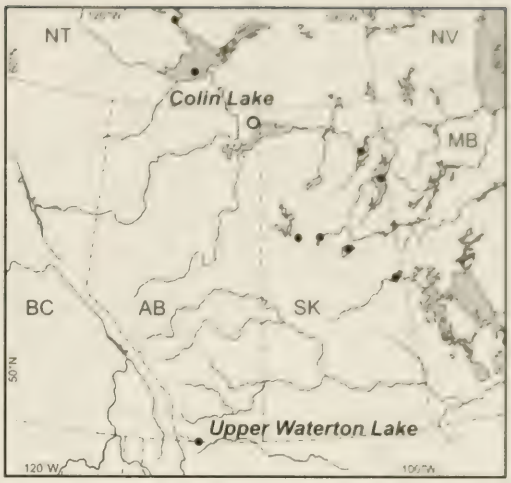

FIGURE 2. Distribution of Deepwater Sculpin in western Canada (data from Scott and Crossman 1973, and Murray et al. 2003). Colin Lake records indicated by open circle.

(*Esox lucius*), Lake Trout (*Salvelinus namaycush*), and Longnose Sucker (*Catostomus catostomus*). Lake Whitefish, Cisco, and Longnose Suckers were the most common species.

All three specimens of Deepwater Sculpin are gravid females, ranging from 62-74 mm SL (Standard Length), with four prominent, large, and straight preopercular spines, a large gap between the dorsal fins, and the gill covers free at the isthmus. Meristic counts of these specimens are consistent with data presented by McAllister (1961) for adjacent populations in Saskatchewan and the Northwest Territories. Dorsal fin spines were (number of specimens in parentheses) 7(2) or 8(1); dorsal fin rays 14(1), 16(1), or 17(1); anal fin rays 14(1), 15(1), or 17(1); pelvic rays 3(6); pectoral rays 16(2) or 17(4). Two of the three had an incomplete lateral line (ending under the last dorsal fin ray) with 32 pores; in the remaining specimen the lateral line continued posteriad to the caudal peduncle and had 36 pores.

These specimens represent the first record of Deepwater Sculpin from northern Alberta, and only the second record for the province (Roberts 1988). The only other known population in Alberta occupies Upper Waterton Lake (49°02'N, 113°54'W) on the Alberta/Montana border (McAllister and Ward 1972) (Figure 2). Nelson and Paetz (1992) suggested the likely presence of Deepwater Sculpin in northeastern Alberta, given the proximity of populations in adjacent Saskatchewan and the Northwest Territories. The closest populations supported by voucher specimens are Great Slave Lake, Northwest Territories (~300 km NNW) and Wollaston (400 km SE) and Reindeer Lakes (520 km SE), Saskatchewan (COSEWIC 2006*). Records from Lake Athabasca in northwestern Saskatchewan (~100 km ESE, COSEWIC 2006*) are not supported by voucher specimens. The specimens from Colin Lake fill this gap, and further suggest that additional populations of this enigmatic cottid remain undiscovered in the northern portions of its range. New populations continue to be discovered as deepwater habitats are systematically sampled (i.e., Murray et al. 2003; COSEWIC 2006*).

Although typically encountered at depths greater than 44 m (Scott and Crossman 1973), this species is occasionally found at much shallower depths, especially as larvae and juveniles (COSWEIC 2006*); Rawson (1951) collected specimens in 1 m of water in Great Slave Lake, while McPhail and Lindsey (1970) documented specimens from 4-6 m in Great Bear Lake. Alex Peden (*in* McPhail and Lindsey 1970) suggested that this fish is probably concentrated in deep water during the summer and moves inshore in the fall. The discovery of Deepwater Sculpin in Colin Lake is thus somewhat unusual in that the lake is not particularly deep, with a maximum depth of only 25 m. Further studies to determine seasonal distribution patterns within the lake and any unique biological characteristics of this population would be valuable. It is worth noting that Colin Lake is connected via the Colin River to the Saskatchewan side of Lake Athabasca (approximately 20 km to the SE) where depths can reach 124 m. It is likely that trapping efforts in deepwater habitats of Lake Athabasca will provide additional records. However, there are currently no data to support the use of the Colin River as a post-glacial movement corridor between Colin Lake and Lake Athabasca.

The only populations of Deepwater Sculpin currently given protective status in Canada are the Great Lakes – Western St. Lawrence populations, which were listed as Threatened by the Committee on the Status of Endangered Wildlife in Canada [COSEWIC] (Parker 1988) but have recently been downgraded to Special Concern (COSEWIC 2006*), and are on schedule 2 of

the Canadian Species At Risk Act (SARA). Western populations (which include the new population discussed herein) were designated Not at Risk in 2006 (COSEWIC 2006*).

The gill nets used to capture these Deepwater Sculpins were deployed as part of a Shortjaw Cisco (*Coregonus zenithicus*) survey in the Canadian Shield region of Alberta (Steinhilber 2004*). Our recent experience suggests that deployment of cyalume light stick-baited wire minnow traps in deepwater habitats is more effective at sampling Deepwater Sculpin than are small-mesh gill nets. The effectiveness of this technique has not been previously discussed in the literature. Long-term surveys of Lake Saganaga on the Ontario/Minnesota border have primarily used small-mesh gill nets (Etnier and Skelton 2003). Between 1986 and 2003, only one specimen of *M. thompsonii* was taken. Use of light stick-baited cylindrical wire minnow traps during summer 2004 per our request resulted in capture of 10 specimens (D. A. Etnier, personal communication). Similarly, during 2003 we provided Fisheries and Oceans Canada personnel on Lake Nipigon with light sticks and traps that were set simultaneously with their gill nets, with similar results (A. Van Ogtrop, personal communication). Other researchers working on Deepwater Sculpins have had similar experiences (T. Sheldon, personal communication; COSEWIC 2006*). We thus strongly recommend the use of this technique over small-mesh gill nets for assessing presence/absence of Deepwater Sculpin.

Acknowledgments

We thank B. Meagher for field assistance. Collecting was conducted under permit 401 FR issued to M. Steinhilber. D. Neely was supported by a grant from the British Columbia Ministry of Fisheries.

Materials Examined

All specimens are deposited in the holdings of the Royal Alberta Museum, Edmonton. PMA L01.33.319, *Myoxocephalus thompsonii*, *n*=1 (74.0 mm SL), Colin Lake, 59°33'12"N, 110°9'30" W. 15 September 2001. Collectors: M. Steinhilber, B. Meagher. PMA L01. 33.311, *M. thompsonii*, *n*=2 (62.7-73.0 mm SL), Colin Lake, 59°33'28"N, 110°5'8" W. 15 September 2001. Collectors: M. Steinhilber, B. Meagher.

ZOOLOGY

The Clements Checklist of Birds of the World 6th Edition

By James F. Clements. 2007. Cornell University Press, Sage House, 512 East State Street, Ithaca, New York 14850 USA. 864 pages. U.S.$59.95. Cloth.

If you travel outside of North America [or any other home territory] you will have to face *the* question. Is this bird species one I have seen before? There are so many look alike birds that are different species in some areas and the same species in others. You can wonder about crows, oystercatchers, stilts and the plethora of wagtails. Or is this bird with the same or a similar name to a look-alike home species, the same or a different bird. For example are Willow Grouse, Red Grouse and Willow Ptarmigan the same species? It can be really confusing.

Enter Dr. James Franklin Clements [1927-2005], an orphan who served in the U.S. merchant marine and navy before going to college. In the Korean war he was in the air force, before finally settling to get his Ph.D. in 1975. His thesis became the first edition of a check list of the world's birds. Because of ever-evolving taxonomy we are now at the 6th edition.

Clements has produced a list, simply a list, of all the known bird species and subspecies. Producing such a simple list is a very complex task indeed. It must have felt like trying to resolve the unresolvable on many occasions. So here we have this simple list and can ask how useful is it? Theoretically, I should be able to check out a bird that I am unsure about. Looking it up in Clements should allow me to clarify the bird's status and decide whether it can be added to my life list or not.

How well does this work? The first problem is you must use the same English name as Clements. Nowhere is there a list of alternative names. If you look for Melba Finch in the index you will be disappointed. You will need to use either Green-winged Pytilia or look for the genus *Pytilia.* The North American bias is shown by *Circus cyaneus* being called Northern Harrier as opposed to Hen Harrier [the older name].

Now we come to the sticky issue of splits and lumps. The North American Magpie is split from its European counterpart, as is Hooded and Carrion Crow. Clements lists the Somali Ostrich as a subspecies, *Struthio camelus molybdophanes*, whereas most recent literature gives this distinctive blue-necked bird separate species status [*Struthio molybdophanes*]. Similarly the brightly coloured barn swallow found only in the Nile delta is not split from its more common cousin. Again this is listed by some as a separate species. Egyptian Swallow, *Hirundo savignii*. The *vegae* Herring Gull is separated as East Siberian Gull. This is open to question and recent work suggests more research is needed. Certainly I have found it difficult to see a difference in the field. Is it a little darker than a Herring or was I being deluded by poor light?

Each entry is accompanied by a description of the species range. These ranges are useful when comparing species. For example, my list for Mongolia includes Pink-footed Goose, *Anser fabalis*. The range for Pink-footed Goose in Clements does not include Mongolia, whereas the Bean Goose, correctly *Anser fabalis*, is present. Clearly this is an error in the Mongolian list, probably due to translation problems, that was quickly resolved.

However, the ranges given for other species are less useful. Clements can be forgiven for minor lapses such as the range of the Northern Wheatear or Crested Auklet – given as Siberia. The birds I saw on the eastern-most coast of Russia this year were technically in the Russian Far East – not Siberia. Siberia does not extend to the east coast. This is minor compared to Houboura and Macqueens Bustards. Clements splits these two birds and gives Macqueens a range of the Nile to .... Pakistan. *The Handbook of the Birds of the World*, Volume 3, cited as the major reference, does not split this species but lists it as a subspecies, *Chlamydotis undulata macqueenii*, and correctly gives the range as NW Kazakhstan to .... Mongolia and Northern China. Similarly Clements does not mention the range extension of Cardinal and House Finch into eastern Canada.

I have checked to see if some of the recent discoveries are included in this check list. Scarlet-banded Barbet and Long-whiskered Owlet are, but the two most recent discoveries, Large-billed Warbler [the 1867 reference is given but not the recent March 2007 capture of two birds] and Gorgeted Puffleg, [May 2007] are not.

Having one coherent checklist is extremely valuable for the travelling birder. It still does not solve all the issues with a changing taxonomy, but at least you can use it as a solid foundation for your records. You will still have to research current taxonomy and recent discoveries and decide which birds you will accept as a full species.

Incidentally, I make it a point never to directly mark books. I use post-it notes or equivalent. I will make an exception for this one book. Not only is it set up to be

ticked, but it is a good idea to add information on species as new data become available. That is until version seven is printed.

Birds of Europe, Russia, China and Japan: Passerines, Tyrant Flycatchers to Buntings

By Norman Arlott. 2007. Princeton University Press, 41 William Street, Princeton, New Jersey 08540-5237 USA. 240 pages. U.S.$29.95. Paper.

My wife and I recently decided to visit northern China and Mongolia [the Silk Road]. This left me with a dilemma; which bird book or books would I need to take to get adequate coverage. I did not want to pay $100 or more for a paperback copy of *A Field Guide to the Birds of China* (John MacKinnon and Karen Phillips, Oxford University Press, New York). My *Birds of Russia* (Flint et al.) gives fair coverage but the illustrations are not as precise as I would like them, particularly for warblers, etc. *Birds of China* (De Schauensee) only illustrates some of the species and gives descriptions of range only and you need a thorough knowledge of China's geography to follow these descriptions. *Birds of India* (Grimmett et al.) is a much better guide with a lot of species covered [as winter visitors], but the coverage is far to the south so the range maps are useless.

Then Princeton announced *Birds of Europe, Russia, China and Japan* and I thought it would be just right for my purposes. While the book covers only the passerines (from Tyrant Flycatchers to Buntings), it is exactly these groups for which I needed a better, more up-to-date book. The non-passerines, like ducks and gulls, tend to be more distinctive and are suitably covered in previous books.

Technically Princeton calls this book an illustrated checklist. Each species has an illustration or two with very brief facing-page text. At the back of the book are range maps. While the text presents little about each species but key features, it is perfect for the traveller. It measures only 5" × 7" × ½" [12.5 × 17.5 × 2 cm] and weighs 14 oz [100 g or around half a normal field guide].

The range maps are 2" × ⅞" [5 × 2 cm] and cover from Britain to Kamchatka, from Svalbard to Northern India. As there are no country boundaries [these would make the little map too cluttered] I found it helpful to create a mask with a piece of clear plastic sheet. I traced the outline of the map in blue, then, using Google Earth as a guide [Google Earth has a similar orientation to these maps] I shaded in transparent yellow the region I plan to visit. I can now place the mask over each map and quickly see if I will be in any bird's range. This was somewhat satisfactory. I compared my list created with the mask to actual trip lists and I was in error by around 15 percent.

Although the book's title suggests it covers Europe, Russia, China and Japan, the maps go much further. For example it includes the Nile Valley Sunbird of the Middle East and the Purple Sunbird of India, as well as the geographically restricted Sinai Rosefinch and Sub-Sahara's Blandford's Lark. I am not sure of the author's rationale for including birds like the Rosy-patched Shrike, a purely African species [but I am happy he did so].

The critical illustrations are those of difficult to identify birds such as warblers and some finches. Arlott has been illustrating bird books for many years [my first Arlott book is over 40 years old]. His skill has grown dramatically and his most recent work is top quality. My copy has all the illustrated species looking a little dark. [Technically the hue is correct but the illustrations are over saturated and this is part of the printer's quality control. North American readers will see this when looking at the Cedar Waxwing and Varied Thrush illustrations. Both are way more intense than the real birds I have seen this year.] In detail though the artwork is excellent. When I looked at Arctic Warbler and try to separate it from it congener leaf warblers or the Beautiful Rosefinch from its relatives then the relevant field marks are apparent. North Americans will have no difficulty identifying wood warblers using this guide, even with the intense colours. [I was surprised to find over 40 "North American" species, such as Wood Warblers and Icterids, have been seen in this region as vagrants.]

This book solved my problem and will be ideal for other travelers to this large region. I look forward to a similar book on the non-passerines. I hope Princeton does well with their checklist series [I believe they have a dozen titles] as they are so much more convenient when luggage weight is critical.

Deep Alberta. Fossil Facts and Dinosaur Digs

By John Acorn. 2007. The Royal Tyrrell Museum and The University of Alberta Press, Edmonton, Alberta Canada. XII + 186 pages. $26.95.

Early on the recognition of our country's rich resources was often a reactive response, rather than proactive endeavours. It was in response to the U.S. activities, primarily those of Barnum Brown (1873–1963) of the American Museum of Natural History, New York, that the Canadian government in early the 20th century began their vertebrate paleontological activities in the Canadian west. First under the Geological Survey of Canada, followed by the National Museum of Canada (now, Canadian Museum of Nature, Ottawa). These activities were central to what has been called "The Great Canadian Dinosaur Rush" (see David Spalding's *Into the Dinosaurs' Graveyard*, Doubleday Canada, Toronto, 1999).

Despite these efforts, and the bountiful treasures collected and studied, it wasn't until the late 1960s that the Province of Alberta, host of the majority of these activities, was able to begin to take control of its own paleontological resources. Provincialism – restriction of outside exploitation – emerged. This occurred with the materialization of the University of Alberta, Edmonton, establishing its own paleontological program of education and research, supported by the *Vertebrate Paleontology In Alberta* conference in 1963 (University of Alberta, 1965) in addition to the establishment of the Provincial Museum of Alberta (Edmonton), which opened in 1967. What followed was a slow eruption of discovery, research, tourism and marketing savvy. John Acorn's *Deep Alberta* skims the surface of all that is sexy in paleontology in Alberta. And as most will see, there is a lot to witness.

Acorn's guide, based on his CKUA radio series by the same name, is not quite similar to the other popular guides to Alberta's paleontological wealth, *The Land Before Us, The Making of Ancient Alberta* by the Royal Tyrrell Museum of Palaeontology (Lone Pine Press, Edmonton, 1994) is more of a complement to its own gallery (somewhat similar to the Royal Saskatchewan Museum's Earth Sciences gallery guide, *Geological History of Saskatchewan* by John E. Storer (Government of Saskatchewan, Regina, 1989)). Nor is it obviously as in-depth as *Dinosaur Provincial Park* (edited by P. J. Currie, Indiana University Press, Bloomington, 2005), a symposium volume summarizing all the major taxonomic groups found within the park. *Deep Alberta* is designed similar to a field-guide, with one-page descriptions and colorful illustrations of species, or non-taxonomic themes.

Alphabetical in its listings of themes, creatures, and places, each item listed is given usually a page of text, accompanied by a full page illustration, often a photograph of an exhibit at the Royal Tyrrell Museum of Palaeontology. These range from mosasaurs, those snake/lizard derivatives from the marine environment of the Cretaceous Period, the *Chasmosaurus*, the horned-dinosaur familiar to the fields of Dinosaur Provincial Park, to the singularly rare *Atrociraptor*, the "savage robber" skull found near Drumheller – only one partial skull of this is known.

Of place, from the badlands near Drumheller to the Milk River regions are few. The thematic questions include "How do you Know Where to Dig?", an often made public query. Yet, surprisingly, a hot topic like extinction is not addressed. Of people, the likes of Barnum Brown and the Sternberg family (three generations of which have worked in Alberta) are briefly brought to the fore. Appended is a list of most of the Ph.D.'s who are currently at play in the paleontological field of Alberta. Those who have contributed research but lack graduate documentation, or who have provided discoveries without institutional support, are not recognized in this summation.

Since the discovery by Joseph B. Tyrrell (1858–1957) over a century ago of an *Albertosaurus* jaw, later culminating with erection of a provincial museum specifically dedicated to paleontology (The Royal Tyrrell Museum of Palaeontology) and the designation of Dinosaur Provincial Park as a World Heritage Site, the Province of Alberta has ample reason to show off its fossil resources. Acorn's *Deep Alberta* is a primer of a primer, a very first introduction to this wealth. Acorn has much to choose from in his summation of paleontology of Alberta and will likely be another useful marketing tool to maintain the visibility of this science in the minds of the public. The treatment of these resources by other provincial jurisdictions should take note. Alberta is not the sole place for paleontology. There is a lot more to see.

Gibson's Guide to Bird Watching & Conservation

By Merritt Gibson. 2007. Nimbus Publishing Limited, Halifax, Nova Scotia, Canada. 214 pages. $16.46.

This small bird watching guide to the maritime provinces is a tribute to the birds of Nova Scotia, Prince Edward Island and New Brunswick. It is also a tribute to the ornithologists and bird-watchers of the area, the unsung heroes who for the past several decades have been the backbone of bird conservation and study to preserve habitat, protect endangered species and pro-

mote birding. The reader is introduced to a variety of birds and a variety of birders following the colourful pages of anecdotes, life histories and illustrated birds.

The book does not try to describe all of the birds which regularly visit the maritime provinces of Canada. It is not a field guide to all birds. It is a book for bird-watchers and conservationists and introduces the reader to several birds, each of the sea, the coast, the shore, freshwater, the forest, agricultural lands, and finally towns and gardens, in that order. The book is divided into the seven sections named above with an introduction to each section and ending comment introducing birders amateur and professional studying within each of the sections and involved in the stewardship of habitat. Three to seven birds are described in some detail in each section. The description includes anecdotal stories of the birds, their habitats, origins of their common name, behaviour, nesting and egg-laying behaviours and chick hatching and rearing behaviour. Whether one is ready to brave the wind and waves to spot birds, or maybe just sit in an armchair by the window, the text leads you to appreciate the diversity of birds present in the Maritime Provinces and the possibilities of discovering or re-acquaintance with species which have always been present and probably have been visible many times.

Conservation is one important focus of the book and the end of each chapter gives some detail on the work of amateurs and professionals who research, monitor, and care for the different populations of each bird species mentioned. Throughout Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland, many different bird populations are in decline, especially but not exclusively, species mentioned in the book. Different programs are in place to monitor and conserve lands inhabited by these birds, and programs are being developed to make the public aware of the trends in bird populations. This book is one of those awareness projects.

I read the book quickly and then went back over the chapters more slowly to savour the stories of birds I know and the birds mentioned which I would like to see one day. It is an exciting book for a part-time birder and one which taught me not just about the birds but even more about the state of the shoreline, the wetlands, the forests and the agricultural fields. To the visitor, the land changes little, but to the resident, there are problems and potential solutions. The solution is often awareness and information. I applaud the researchers for their work and Merritt Gibson for bringing it together. The book also serves as a delightful picture book illustrated by Twilia Robar-DeCoste with drawings of birds, birds in their natural settings, landscapes and seascapes to show perspective and the beauty involved in the study and enjoyment of birding on Canada's East Coast.

Ladybugs of Alberta: Finding the Spots and Connecting the Dots

By John Acorn. 2007. University of Alberta Press, Edmonton, Alberta, Canada. 169 pages. $29.95.

This is an important book about insects for naturalists. It has field credibility. Acorn reviewed and understands the writings of the experts on lady beetle identification and ecology in North America. Acorn studied the specimens that collectors in Alberta deposited in collections. But most importantly, he was in the field in Alberta chasing and watching and photographing lady beetles. The result is a guide, written by an expert, which will be valuable before someone starts chasing lady beetles and will continue to provide insights as a person's expertise grows. And it is accessible; virtually anyone will be able to use it.

What can you do with this book? First and foremost it is possible to identify the lady beetles (a.k.a. ladybugs, ladybird beetles, Coccinellidae) that live in Alberta. The combination of excellent colour drawings, photographs, plus key features highlighted in text make it possible. In addition the range maps, both range in Alberta and much of North America, notes on food and habitat preferences give some guidance, to reduce the probability of an embarrassing misidentification. The difficult identifications are not glossed over. The necessity of dissecting genitalia to distinguish some *Hippodamia* (e.g., *glacialis* and *quinquesignata*) and the significance of chromosomal differences between *Chilocorus stigma* and *C. hexacyclus* are covered clearly, with humour and insight.

Most authors would have taken the easy route and restricted themselves to the big showy lady beetles with which most naturalists are familiar. However Acorn tackled the "lesser ladybugs", a daunting task to make what is known about *Scymnus* and *Hyperaspis* and *Brumoides* widely available, including both features that make species level identifications possible and some natural history. Acorn deserves credit for persevering and including the lesser species, especially considering the extra work, almost double the number of species, and that they are not as charismatic to general naturalists and that little is known about them. He engenders interest in these little beetles.

In addition to identification and species accounts, there are substantial sections on ecology, behaviour, and history of coccinellid study in Alberta. The hot topic of the influence of introduced species on native species is attacked head on. It starts with a perceptive critique of the functionally useless Nature Canada attempt to coordinate a citizen science project on lady beetles in the 1990s. His says that a prejudgment, introduced species are bad, led to many of the problems. In my view, the other key problem was that there was little or no quality control that compromised the value

of the data. What was needed was Acorn's book, or listening to field entomologists, during the planning process. The discussion continues with an assessment of the Evans' hypothesis that native species have constricted their range to ancestral habitats, that is have become less common in extensively human altered habitats (farmland and suburbia) after the arrival of introduced species such as the seven-spotted lady beetle. Refreshingly, he is able to present his own data to support his views. His views about ecological change, conservation and invasion biology are clear, logical and worthy of discussion.

The style deserves special mention. It is highly credible, yet at the same time there is a breath of whimsy and fireside chattiness. A fine example is the description of taste-testing. You will not look at a brightly coloured lady beetle the same after you read this.

What bothered me during my initial readings? The first was that I wanted more detail, more data. But, this is a book for generalists and not the appropriate place for the level of detail I want. Second were those couplets. Each species account includes a quirky, rhyming couplet. I did not understand many at first, but they did grow on me. Perhaps they are like beer, an acquired taste. Third were the common names. The Entomological Society of Canada is working to provide consistent, standard common names for insects, just like we have for birds. However, many were ignored, for example *Mulsantina picta* here is the Painted Ladybug, not pine lady beetle. However, some of the newly coined names hit the nail on the head and deserve to be maintained. My favourite was the Once-squashed Ladybug, a cryptic species in the same genus as the Twice-stabbed Ladybug. Yes, it needs to be squashed on a microscope slide to examine its chromosomes in order to be identified. Brilliant. These are minor complaints. The identification sections are worth the whole price of the book. The discussion of introduced species is worth the whole price of the book. The description of how to taste a ladybug to assess its palatability is worth the whole price of the book.

Our understanding of foods, habitat use and phenology (seasonal activity) is not as well developed in North America as it is in Great Britain and Europe. People armed with this guide, will have the tools to be at the forefront in remedying this situation. Compilations often function as a catalyst for a quantum leap in interest and new findings by curious naturalists. I predict this book will provide another great example in western Canada.

A New World of Animals: Early Modern Europeans on the Creatures of Iberian America

By Miguel de Asua and Roger French. 2005. Ashgate Publishing Ltd., Aldershot, England. 235 pages. $89.95

How would you describe a beaver to someone who has never seen a beaver? Is it simply a 20 kg rat with thick fur and with something that has the texture and consistency of an elephant's ear sticking out of its backside? That person to whom you are giving the description might be forgiven for disbelieving you. What about a whole forest of new animals including muskrats, otters, woodchucks, skunks and any of the larger forest-dwelling species? In North America we have an abundance of animals which were unknown in the Old World before European exploration. Combine these animals with their South American counterparts and add birds, reptiles, amphibians, and insects known only to the New World and you have the basis for the book given to us from Miguel de Asua.

For the history buff and the technophile who wants to track down the classic literature of the conquest of the Americas, this book is a new door to obscure literature of natural history. Miguel de Asua is an Argentinian professor at the Universidad Nacional de San Martin and Roger French was English, from the department of History and Philosophy of Science at Cambridge University, UK. Their work focuses on the animals found by early explorers of the Americas, particularly South America though reference is made to animals occurring in North America as well. The reader is introduced to many of the early writers describing the newly discovered lands, and emphasis is placed on the animals, birds, reptiles, amphibians and insects which the authors noted at the time.

From the earliest explorers, Columbus and his followers, the discovery of the New World has been a discovery of the beauty and ferocity of many new and exciting creatures. Columbus returned with birds, skins and many stories trying to describe the richness of nature which he found and impress his audiences with tales of strange and exciting beasts. Written accounts which survived from his time sought to identify the animals, birds and reptiles using the experience of known animals and the descriptions are interesting associations with European and Asian animal forms put together to construct forms which would be within the experience of the audience. So bison looked like camels or cows, armadillos looked like striped foxes and manatees looked like large puppies.

For two hundred years the animals of the New World were exotic, unique and objects of wonder in Europe. Even as the years rolled on with more and more literature being accumulated from explorers, naturalists and then colonists with animals imported into Europe as exotic pets and zoo specimens, the earliest descriptions survived and were repeated. De Asua takes us on a literature search, naming writers, quoting their writ-

ings and showing the parallels as information, disinformation and wild speculation was accumulated, repeated and refuted.

This is a new study of scientific literature because of its origins and perspectives. First of all it is centred on South America with only some brief mentions of North American mammals. Secondly it is restricted to the writers first in Spanish then in central Europe, all of whom wrote in their own language for audiences in their local areas. Only toward the end of the literature covered in the book are we introduced to English sources though the names are obscure here as well. A good conclusion is added where the ideas of the sailors, soldiers, functionaries, friars and adventurers each had their day and their utility in telling a part of the natural history story. The opinions and wisdom of the native peoples of the Americas are not given much consideration because of course they did not write to Europe and the conquerors formed their own opinions based on the utility of the natural wildlife to their own needs, not the inherent worth of the ages of native wisdom.

This is neither an easy book to read nor a simple historical storybook. It is a history of intellectual thought and discovery. There are many gems of thought included but the reader needs to be attentive to the thesis of the writer not simply to the many repetitions of the details.

Penguins of the World

By Wayne Lynch. 2007. Firefly Books, 66 Leek Crescent, Richmond Hill, Ontario L4B 1H1 Canada. 175 pages. U.S.$24.95. Paper.

If you take one of the most photogenic birds in the world, living in the most pristine habitat and send forth a remarkable photographer, can you fail? No!

The hard part about penguins is getting to where they live. Then anyone can point- and-shoot and get a fine photo. The appearance of penguins is so charming that failure is not an option. A quick thumb through the photos in this book will show how Lynch can take such a good photo opportunity and make the result magnificent.

But let us look at the text first. In a smooth flowing narrative the author takes us through the lives of the world's 17 penguin species. He covers the origins and ancestry of this long-lived family. Most intriguing is Lynch's description of a five foot seven inch prehistoric bird. Now that would have been a sight! The author explains why penguins are shaped the way they are and the uniqueness of their adaptation to sea life. He describes their habitat. You may be surprised to realise that most species live in the temperate [not polar] region. With humour, he explains their sex lives and the advantages of their marriage and divorce systems. He follows their lives from egg to adulthood. In all of this he make these birds sound human. Or is it that we humans are like penguins – after all they have a much longer lineage?

From sex to family life, from feeding to predators the author weaves a delightful tale of the delightful creatures. In addition you will get to know some of the penguins, sometimes less-than-delightful, neighbours. Only a photographer as good as Lynch could make a pair of Sheathbills look cuddly. He also adds a chapter on the northern counterpart of penguins, the alcids.

An appendix lists all the penguin species, with a range map and photo for each one. This is not a field guide as there is no species description. There is, however, a small photo of an adult. The range maps and distribution notes are clear and useful. Lynch notes the population size and the species status. These range from a scant 1000 or more pairs of Galapagos Penguins to 10 million Macaronis.

The photographs are wonderful. Many of them are so balanced in format as to look posed. This speaks of the infinite patience and possibly some good luck that Lynch had on his trips. One notable point is the sunshine. In my trips to polar regions I rarely see the sun, yet many of his photos bask in glorious light – more patience I think. There is a photo of a braying penguin showing the backward-facing spikes on his tongue in remarkable detail. There are numerous portraits of chicks, with and without parents, that are irresistibly charming.

I have seen 10 out of the 17 living species. To see six of the remaining species I must visit New Zealand and the islands that lie to its south, a difficult and very expensive area to reach. But the lure for a penguinophile is undeniably very strong. However, if you have never seen wild penguins and are not likely to do so, then this book is the next best thing. Buy it and enjoy it, for only the smell is missing.

ROY JOHN

Raptors of Western North America and Raptors of Eastern North America

By Brian K. Wheeler. Princeton University Press, Princeton, 41 William Street, Princeton, New Jersey 08540 USA. Hardcover. 544 pages and 430 pages, respectively. U.S.$29.95.

The hardcover editions of these two volumes were reviewed in Canadian Field-Naturalist 118(1): 142-143 by Houston and John. These books have now been issued as paperbacks, reducing their cost [U.S. $49.50 Cloth] and weight. There are no updates or additions.

The Sand Wasps: Natural History and Behavior

By Howard E. Evans and Kevin M. O'Neill. 2007. Harvard University Press. Cambridge, Massachusetts, USA. 340 pages. U.S.$49.95 Cloth.

As a baby-boomer "bugster", two writers had a tremendous effect on my early enthusiasm for insects: Edwin Way Teale and Howard Ensign Evans. Sadly, both have passed on, but their legacies live on, and it was with pleasure that I agreed to review a book on the sand wasps (the subfamily Bembicinae of what is now the family Crabronidae, formerly included in the Sphecidae) coauthored by Evans, and created from his notes, ably revised and updated by his former student and colleague Kevin O'Neill.

As one might expect, this is indeed a book for specialists. However, it is also clearly written, and a model for studies of how comparative natural history and behaviour can be informed by phylogeny and brought together in a synthetic fashion. If you have read *Wasp Farm*, Evans' 1963 classic of popular science writing, you understand what this is all about. If not, the first two paragraphs of the introduction to *Sand Wasps* provide a concise, if not downright brilliant, justification for this sort of work. Later, on page 5 in the section on "Sand Wasp Natural History/Sand Wasp Science" the authors provide a very fine defense of natural history in general. The overall purpose of the book is to update Evans' previous works on the sand wasps, and it's clear that to appreciate all of the details of the present volume, one really should have read the works that preceded it. But having skipped that step, I still found the book a pleasant and interesting read.

The book begins by putting the sand wasps in context, both with respect to their biology and their classification. After that, chapter-length summaries are provided of what is known about the wasps, on a tribe-by-tribe basis. I found myself getting a bit bogged down in details during Chapters 2-7, but a student of sand wasp biology would find them riveting, I'm sure. My only criticism of this part of the book, which lays out the evidence to be synthesized in the remaining chapters, is that no summary is provided of the classification used, to which one could refer back while working through the tribal accounts. I also found myself wishing for a gallery of illustrations, showing the various genera of sand wasps side by side. For general readers from eastern North America, the most useful portion of these chapters will probably be the account of cicada killer wasp biology (genus *Sphecius*), in Chapter 3.

The synthetic portion of the book begins in Chapter 8, "Comparative Ethology of Sand Wasps." Patterns begin to emerge, but so does an overall impression of great diversity, tremendous complexity, and many unanswered questions. The theme of phylogenetic reconstruction enters strongly at about page 260, at which point I became quite nostalgic, since this was always my favourite aspect of Evans-school wasp studies in the past. I found myself wishing that I were reading an updated account of the evolution of all solitary wasp behaviour, not just that of one subfamily, but the focus here is clearly on the sand wasps alone. My interest was strongly piqued again, however, by the section on sand wasp conservation. The preservation and promotion of open, erosional habitats is becoming increasingly important to those of us who study organisms that require such places (yes, I'm thinking here of tiger beetles), and it is encouraging that sand wasp biology adds further impetus to this cause.

As a work of entomology, this book is superb. I doubt many people outside the hymenopterists' guild will read it cover to cover, but I do think that various portions of the text have important implications for evolutionary biology, entomology, natural history, and conservation biology. And as a final offering from one of the great naturalists of the last century, it is a welcome book indeed.

JOHN ACORN

Department of Renewable Resources, University of Alberta, Edmonton, Alberta T5T 5L7 Canada

Tracks

By D. C. Jackson. 2006. University Press of Mississippi, 3825 Ridgewood Road, Jackson, Mississippi USA. 279 pages. U.S.$25. Paper.

Tracks is a collection of 23 short essays, each ranging from 2 to 26 pages. Each essay is built around a personal story of hunting, fishing, trapping or ramblings, and Jackson uses these narratives to provoke thought and contemplation regarding our interactions with and place within nature. While I think his goal is very worthwhile and of great value to anyone interested in understanding our relationship with the environment, I found that he was only sometimes successful. Often the stories are simply entertaining anecdotes, and some essays miss the mark entirely. This is not to detract from the compilation however, as a range of success is to be expected in such a compilation of wide-ranging individual stories. When successful, the author is very insightful and provides much food for thought.

Given this objective however, the musings and philosophies are somewhat confined and repetitive in that all are focused around stories of exploitative nature (hunting, fishing, trapping) whereas some of a non-exploitative nature (camping, hiking, canoeing, drifting, etc.) would be welcome. Such a broader approach would illustrate the connection between a contemplative man and nature in a way that does not require the taking of life. As is, I am left with the vague unease that to "connect" with nature it is necessary to kill something. Dr. Jackson is a professor at Mississippi State University and, given that, I would have appreciated some stories and deep reflections arising from his time in the field on his research. It would show the natural environment giving rise to musings in some other aspect of his life besides the exploitative areas of fishing/hunting/trapping.

Tracks is an interesting book, though I would not recommend it as a must-read. Sometimes the "philosophy" or musings felt forced, but at other times they were very appropriate, flowing from the personal anecdote. The first chapter "Wilderness Before Dawn", really captured my attention and made me hope that I was in for great insight and original perspective. This hope, while not entirely fulfilled, was not entirely defeated either. These essays are clearly intended for a broad audience of readers and in many ways refreshed exquisitely enjoyable past memories for me. I grew up on stories from the magazines *Outdoor Life* and *Field and Stream*, and the stories here are a cross between that type of article and a primer on environmental ethics. As a bridge between outdoor adventure stories and a contemplative approach to nature it is very successful. In addition, while I may not have gleaned profound new insight from the writings, I did learn, and think I have a better appreciation, and respect for, the Deep South of the United States over that when I began the book.

All-in-all *Tracks* is a pleasant read but I would not recommend it as delivering particular insight or a message that we have not heard previously (with the exception of "Wilderness Before Dawn"). For those interested in the rural culture of the Deep South (at least several decades ago), it would be a very useful book. It is the type of book, I think, which is best read in front of a warm fireplace on a cold winter night.

SEAN MITCHELL

St. Francis Xavier University, Antigonish, Nova Scotia B2G 2W5 Canada

Why Don't Woodpeckers Get Headaches? And Other Bird Questions You Know You Want To Ask

By Mike O' Connor. 2007. Beacon Press, Fitzhenry & Whiteside Limited, 25 Beacon Street Boston, Massachusetts 02108 USA. 209 pages. U.S.$14.95.

The book *Why Don't Woodpeckers Get Headaches?* is a collection of letters submitted to *The Cape Codder* in the "Ask the Bird folks" column, and answered by Mike O'Connor who is a bird watcher, the owner of a birding store, and a born comedian. The letters ask questions of interest to any backyard birder, ranging from how to attract Bluebirds, to buying the bird bath that's right for you (and your birds) and how to get rid of a squirrel infestation.

The book is divided into eight chapters, each related to a particular area of backyard birding. The first section deals with bringing birds into your yard. O'Connor gives several important tips to attract various birds to your yard, such as having a proper nest box, leaving food that is suited to the birds you hope to attract, having suitable habitat, and most importantly, if you want these birds to stay in your yard, offering birdhouses with low rent, an example of the author's humourous approach.

Other chapters of the book deal with food issues such as: Peanut Butter is it safe? What birds can you attract with oranges? Should you replace your rotten seeds? Another chapter discusses providing some basic comforts for your avian friends: selecting a quality bird house is obviously a key issue, and is talked about extensively. It is safe to conclude from the various entries that, in housing birds, simplicity is key, and while the four story summer villa with the small picket fence and lawn included may look great at the store, your birds would probably prefer the cheaper wooden box. Also, providing a heated birdbath is quite important; contrary to popular belief, birds don't enjoy a chilly swim in the middle of December any more than we do.

Even though this book mostly deals with attracting birds, and encouraging their visits, there is an entire section devoted to bird-related problems. People write in to ask: Why are some woodpeckers more attracted

to metal chimney caps than the peanut feeder? Why do birds insist on chirping in a new day at 4:30 in the morning, right outside their bedroom window? And of course, the timeless question; How to stop their new bird feeder from becoming an all-you-can-eat diner for the cunning gray squirrel? O'Connor provides excellent and thorough advice for his readers, even if he hasn't found a sure-fire solution to the squirrel problem.

Why Don't Woodpeckers Get Headaches is a fascinating collection of people's backyard bird triumphs and tragedies. O'Connor is a talented writer, whose quick wit and edgy humour had this reader crying with laughter. Not only does he answer readers' queries with accurate and detailed opinions, he also provides a brief background look into the bird's appearance and behaviour. The illustrations by Catherine E. Clark are well done and the birds are easily identifiable.

This book is aimed at readers of all ages, and all birding-skill levels, from novice to expert. It is well written and gives a new and often amusing perspective to the world of back yard birding. Even people who are not interested in birds will have a great time reading this book and I would recommend it to anyone. So why don't woodpeckers get headaches? Well, if you want to know, buy the book!

JESSICA GAWN

c/o Mission of Canada, 5 Ave de l'Ariana, Geneva 1202, Switzerland

BOTANY

Alaska Trees and Shrubs. Second Edition

By L. Viereck, and E. L. Little (with contributions by D. F. Murray and E. L. Little, Jr.). 2007. Snowy Owl Books, University of Alaska Press, Fairbanks, Alaska. 265 pages. US$24.95. Paper.

Measured in Cranberries, Alaska must be among the wealthiest states in the world. Although this Alaskan hardcopy publication was printed in China, it was produced with major U.S. governmental support. A long-awaited second edition, its underlying data exist elsewhere in digital geo-referenced format online. For some of the most abundant Alaskan species (willows, over 37 *Salix* species occur in Alaska) the authors present text that simplifies relevant details and identifications.

These complex details are all part of Alaska's wild reality and a management that is mainly oriented on commercial goals. The lack of a GAP project in Alaska (otherwise found throughout all states within the U.S.; see http://gapanalysis.nbii.gov/portal/server.pt) leaves it a large and harmful heritage; e.g., lack of relevant biodiversity management information and digital administrative culture. At least the digital data from this book are available in an older GIS format (ArcGIS 9.0 + Metadata) at the Bonanza Creek LTER website (http://www.lter.uaf.edu) raising hopes of great things to come in the future. This matters a lot, because as the book outlines: "An increasing number of people look to Alaska for wilderness that is no longer present in the more developed areas of the world". It therefore represents a global natural resource leadership issue and role model on how we deal and publish on Alaska's biodiversity and wilderness management components that are so crucial to business and human welfare of the global village.

Together with contributions by D. F. Murray and G. W. Argus, the authors summarize in this book (first edition published in 1972) their life-time achievement presenting up-to-date information on over 14 tree and 115 shrub species. The book offers four identification keys (Key to Alaska Trees and Tall Shrubs Based Mainly on Leaves, Winter Key to Deciduous Trees and Tall Shrubs of Alaska, Key to Genera of Alaska Shrubs, Winter Key to Alaska Shrubs). For each of the 132 species, distribution maps, a descriptive text (usually covering leaves, twigs, bark, wood, flowers, capsules, hybrids, habitat, distribution, uses and notes), paintings and photos (44 color plates overall) are presented. I enjoyed the numerous drawings (mostly taken from Forest Service publications). The plant distribution maps present traditional-style, expert-drawn "polygon monsters" with mathematically exact shapes and margins but are unlikely to represent biological reality or relevant landscape gradients. Some of the general species text information one might find in other botanical key references. However, readers interested in Alaskania will appreciate the many species details provided. For instance "Alaska Athabascans eat the fruits raw or cooked in moose fat" (for Silverberry), or "Alaska Indians used the wood for totem poles, dugout canoes, and houses, and made mats, baskets, and ropes from the stringy bark" (for Western Red Cedar).

The reader of this book will appreciate the incredible diversity (and abundance) of willows, birches, and berries (e.g., Blueberry, Bearberry, Cranberry, Huckleberry, Snowberry) in Alaska. But environmental problems, widely cited in geo-botanical publications, such as climate change, endemic species loss, road impacts, overcutting, nitrogen input and general human footprint found throughout Alaska are sparsely treated). Oil development, or pipeline impacts, key features in Alaska's landscape and recent history, and discussed almost worldwide with high-profile books devoted to this issue (see for instance National Research Council of the National Academies 2003), are hardly even mentioned.

The authors maintain a dubious and ecologically non-sensitive view that "...the distribution of trees and shrubs have changed little" since the 1970s. However,

at least the changes for Greene Mountain Ash and Creeping Juniper are described. The concepts of (Landscape) Ecology, Biogeography, Fragmentation, Biodiversity, and related loss of plant DNA are virtually omitted in this book. With great regret one has to see once more that the impact of the Intensive Management Law (signed 1994 by Governor Hickel; maximizing moose numbers through non-science based predator control, and thus severely affecting browsing on shrubs and vegetation Alaska-wide) remains virtually unmentioned. But the impact of ANILCA (Alaska National Interests Land Conservation Act) in 1980, and the number one problem of the Alaskan National Parks, invasive species, is mentioned (over 100 invasive species are referred to, but only 9 are described in this book; for a better description the reader is advised to visit websites such as http://www.ucsusa.org/invasive_species/state-invasion-portfolios.html and http://www.uaf.edu/ces/ipm/plants/index.html). Many of these species were introduced with governmental help, even by agencies that now have to spend huge amounts of their budget to deal with these earlier sins. The book section on Transplanted Native Species I found very informative (e.g., for Sitka Spruce: "During World War II, the U.S. military had an active program of planting trees near bases in the Aleutian Islands."). Other environmental topics mentioned are facts like "Much Alaska cedar is exported to Japan in log form...", or for Sitka Spruce: "Low-grade lumber is made into packing boxes for the Alaska salmon industry". Keep in mind that the Tongass and Chugach Forest is the largest temperate rainforest in the world, with an extensive network of forest roads reaching more than 10 times around the world! Fortunately, the authors leave no doubt that more forest exploitation will occur in Alaska. Such an outlook makes one shiver for Alaska's future well-being; plants included.

But Cranberry juice apart, "Alaska is a land of contrasts in climate, physical geography, and vegetation" providing a great country for botanists with a thirst to explore. Besides many endemics, it harbours the Quaking (Trembling) Aspen (most widely distributed tree in North America) as well as the largest cottonwood known until 1965. And so, the book is full of fascinating Alaskan landscape details such as nunataks, ice fields, permafrost, and some fire history. The prominent botanist Robert Marshall and his historic seedling experiments are also mentioned. But relevant Russian, Chukotkan, Kamchatkan and Bering Sea botany are not further dealt with, nor the links to the Yukon, British Columbia or the circumpolar Arctic.

It appears a botanical religion that a vegetation classification always has to be carried out in such botanical books and landscapes. Therefore, this publication offers 8 main vegetation types and their leading species for Alaska (published by the U.S. Forest Service 1971; but relevant quantitative analysis details are not provided, and one has to trust the experts blindly once more).

The underlying botanical species taxonomy of this book is still in flux, as can be seen in the large number of hybrids, or in the alder, birch and willow species complexes. Such dynamic and complex taxa are not easy to deal with by using classic governmental hardcopy black-and-white publication philosophies (the authors followed for instance the *Flora of North America*, Furlow 1997 and Argus 2004). It is here where readers need more leadership from the experts. Perhaps presenting links with Genbank (http://www.ncbi.nlm.nih.gov/Genbank/GenbankOverview.html) and ITIS (http://www.itis.gov/) would start this concept?

The general audience will appreciate the two Alaskan botanical maps and the four page glossary of botanical terms. A seven page index of Common and Scientific Names, and the six pages of literature are of further interest.

The authors state the contributions from several agencies and funding institutions, including the U.S. Forest Service and the Museum of the North Herbarium Database. Unfortunately, botany is often equated with timber, and, as elsewhere, a governmental forest service focus and its cultural bias can be found in this book. For instance, from an Arctic tundra perspective, I am disappointed not to find any relevant references from S. Walker in this book; the reader is advised to see online for CAVM http://www.geobotany.uaf.edu/cavm. But despite the forestry involvement, the authors still make a nice case that "...the forests of Alaska provide more than timber to the people of Alaska, and the rest of the United States". Well spoken.

This book well describes what Alaska currently has to offer: wide terrain, many new botanical findings that are waiting to be put in order (à la: "we sort 'em postmortem"), and much relevant ecology and sustainable management waiting to be done. Curious naturalists might also want to compare the state of the art in Alaska with the *Flora of adjacent British Columbia* (http://www.eflora.bc.ca). One assumes that the future will likely see digital online species pages, such as already started in Wikipedia and coming forward in GAP and GBIF, with a Biology Google ("Boogle", or Poogle for Plants) just being around the corner. This books makes for a great step towards this achievement for Alaska, its cranberries and beyond.

ENVIRONMENT

The Atlas of Climate Change: Mapping the World's Greatest Challenge

By Kirstin Dow and Thomas E. Downing. 2006. University of California Press, Berkeley, California, USA. 112 pages. US$23.95 Paper.

An atlas suggests maps, and maps there are in abundance in this volume, though it also contains many graphs, charts, diagrams, and informative explanatory text. Although short, this book is packed with useful information and well repays careful study. The atlas is divided into seven sections, each focusing on a different aspect of the climate change story and each preceded by a one-page introduction. For the first five sections, topics are illustrated primarily by mapped data, usually at a global scale, though occasionally focusing on a specific region, such as the Antarctic. The maps are usually supplemented by a few paragraphs providing some additional background or explanation for the displayed data. The atlas is sprinkled with quotes, though these are mostly undated, which rather diminishes their urgency or relevance to the issues.

Part 1, Signs of Change, highlights some warning signs, such as the European heat wave of 2003, and then covers three aspects of climate change that set the context for the rest of the book. These three aspects comprise glacier retreat, weather-related disasters, and changes in the polar regions, areas that have been identified as having particular sensitivity to climate change. These topics are likely to be familiar to Canadian readers through various recent media stories. Part 2, Forcing Change, focuses more directly on the climate system, covering four topics, mostly through charts and diagrams. Two aspects of the climate system are highlighted, explanations for the greenhouse effect and how climate operates in terms of heat transfer across the globe. This section also provides a long-term perspective on climate change, showing the record of carbon dioxide fluctuations for the last 400 000 years derived from ice-core records. Finally, there are some scenarios, based on various model projections, showing projected carbon dioxide increases and related temperature increases.

The following three sections form the bulk of the atlas. With six topics, Part 3, Driving Climate Change, examines greenhouse gas production in more detail, highlighting several critical aspects of modern industrial activity and linkages to fossil fuels, especially transportation and agriculture. Covering seven topics, Part 4, Expected Consequences, paints a grim picture, showing, amongst other consequences, the impacts of rising sea levels, water shortages, and threats to human health. Africa stands out as the region likely to be most severely affected in the last category. One of the most interesting maps in this section deals with cultural losses, including historical and archaeological sites. These kinds of impacts are not often highlighted in discussions of climate change. On the other hand, biodiversity losses and biogeographic changes are given very little attention. Since alterations in plant and animal distributions are some of the more obvious and visible signs of climate change, I found this rather surprising. For Canadian readers, these sections may induce both complacency and embarrassment. Complacency because the maps show that on an absolute basis, Canada does not contribute as much to the problems as other more populous industrialized countries. Embarrassment because on a per capita basis we consume so much compared to so many countries of the Third World. Such reflections form a natural transition to the last sections of the book.

Having provided a gloomy outlook in the previous section, Part 5, Responding to Change, shows what we can do about it, or how we might be able to modify the outcomes at a macro-scale. Eight topics are presented, most of which are focused on institutional or administrative responses, such as carbon trading or development of alternate renewable energy sources. Finally, Part 6, Committing to Solutions, shifts the focus from the global to the local, with some charts showing how individual actions might affect the trajectory of change. For those who want the "nitty-gritty" details, Part 7, Climate Change Data, tabulates various measures of economic activity and consumption on a country-by-country basis. These data underpin the maps and graphics in the rest of the book.

Generally the book concentrates on the more obvious impacts of climate change and the ones that are often the focus of media attention, such as potential limits on water and food supplies. As such, most readers are likely to have at least some passing familiarity with the issues. This book therefore serves as a useful source or companion book for those seeking more background on current issues. More subtle effects of climate change, such as water quality degradation, or cascading effects, such as wildfire frequency changes or aquifer depletion, are not shown, perhaps because these are less amenable to measurement or estimation and mapping. Moreover, the emphasis throughout is on impacts to the terrestrial realm; other than sea-level changes, very little attention is paid to marine systems. Again, this is perhaps surprising given the linkages that have been found between, for example, the ENSO (El Niño-Southern Oscillation) with rainfall and droughts.

Cartographically, the book is attractive, clear, and well-designed. It is apparent that a great deal of thought and care has been paid to the layout, presentation, and overall design. In my view, the design is one of the book's greatest strengths. Many people are "visual learners" and this book will definitely appeal to anyone that prefers graphics to text. Most of the global presen-

tations use the same map projection, with Europe and Africa in the centre and the Americas and Australasia at the extreme left and right. For North American readers, this projection can seem strange, since we are more used to seeing the Americas displayed centrally with other continents on the periphery. Much of the base information is quite complicated but the maps show good use of colour and symbols to convey information and summarize complex ideas. One of the more interesting maps shows greenhouse gas emissions, with countries' size distorted according the amounts emitted. The effect is quite startling, with the dominance of the industrialized regions (USA, Europe, CIS, and East Asia) standing out. Perhaps more telling is the minuscule contribution from Africa, which shows up as a small polygon, despite its large land area and population.

Even with the references and sources, I did find myself wondering exactly how some of the figures underlying these maps are derived, especially because so many of the data are presented at a regional level, where regions may include several countries, and are "binned" into a few categories to simplify cartographic presentation. Uncertainties or error estimates are not provided for the data. Inevitably, there must be some fairly broad assumptions and generalizations underlying the figures. To take one example, what kinds of measurements could be available to allow an estimate of methane emissions on a per capita basis? Are the same or comparable measurements, that is, the same data quality, really available for all areas of the world? How are data integrated even within one country, given that there are different ecoregions and uneven population distribution? How much of the disparity shown is real and how much attributable to varying levels of data available for different areas of the world? In fact, how far are the numbers behind the maps realistic estimates based on reliable instrumentation or simply informed "guesstimates"? Notwithstanding the beguiling presentation, I did find myself asking many questions about the methodology behind the mapping.

Perhaps the greatest drawback with this book is that, because it deals with current and rapidly changing issues, the information presented will quickly become dated. The authors note that no new material was added after spring 2006, but they also indicate that they intend to update the volume, especially after the next Intergovernmental Panel on Climate Change (IPCC) report, expected in 2007 (page 13). It will be interesting to see how future editions compare to this one and whether detectable changes in some of the indicators show up on that time scale. One could argue that such information is better presented on a website, where it could be updated as needed. However, having the information gathered together in book form makes it easier to consult and compare the different maps. The book's greatest advantage is its accessibility, with its clear presentation and distillation of an enormous amount of complex information into a readily understandable format.

An Inconvenient Truth: The Planetary Emergency of Global Warming and What We Can Do About It

By Al Gore. 2006. Rodale, New York, USA. 328 pages. US$28.95 Paper.

I freely admit that I picked up this book already predisposed to dislike it. After all, it's supposedly a book about climate science by a politician, so how good could that possibly be? I am relieved to report that this volume pleasantly surprised me; the book is considerably more readable and worthwhile than I expected it to be. Surprisingly, it also projects, an air of intelligence and careful consideration. Yes, the book is a call to action and a strong statement of a particular point of view, but the hype and hyperbole are at a lower volume than I had feared. More importantly, the book is largely based on solid science and the presentation of that science is done in a remarkably straightforward fashion.

In his introduction, Gore says that the book was developed from a slide show and, judging by the layout and design, that presentation mode has carried over and set the book's style. It is arranged as a continuous narrative, with clear graphs and graphics, some on fold-out pages, colourful eye-catching photographs, short sentences and paragraphs, and large type. Graphics are sourced, though complete citations are not provided. Text and explanatory captions are generally written in plain conversational language. The book surveys the evidence for global warming and outlines the main forcing factors, highlighting the importance of greenhouse gases and the role of human activities in the increasing rate of, especially, carbon dioxide content in the atmosphere.

Gore drives home the message that human activities, in particular industrial activities, are responsible for much of the recent increase in greenhouse gas concentrations in the atmosphere and therefore the increasing rate of global warming. He sets these trends in context by showing, for example, recent rates compared to the carbon dioxide trend inferred from Antarctic records extending back to 600 000 years before present. Other long-term records, such as tree-rings and Greenland ice-cores, are also used to provide perspective. Several times, the point is made that it is not simply the absolute amount of increase that is important but the increasing rate of increase. Taking it as given that global warming will continue, even if actions are taken now to reduce rates of carbon dioxide emissions, Gore then exam-

ines what the implications are likely to be during the next few decades.

The book presents many different types of evidence for global warming and covers a lot of territory. It draws on data and images from across the world. Gore amasses a formidable array of information to support his argument. Some of the topics he features include: droughts and shrinking lakes (including an intriguing sequence of images showing the reduction in Lake Chad), reduction in Arctic ice, shrinking of large ice sheets (notably on Greenland and Antarctica), effects on temperatures and seasonality, impact of rising sea-levels (including the inundation of islands), damage to coral reefs, effects of climate on human health and diseases rates, frequency and occurrence of extreme weather events (including, not surprisingly, hurricanes), and climate impacts on biodiversity and distribution of plants and animals. The evidence for global warming includes some striking "then and now" photographs of glacier forefields showing recent ice retreat. Two issues that also stand out are the effects of exceptionally high summer temperatures, as seen in recent years in Europe especially, and increased storminess, especially on low-lying islands and coastal areas. The evidence and implications are shown from a global and not just a U.S. perspective. This worldwide coverage underlines the urgency of the issues presented, since some of the impacts are not just hypothetical but are being felt by people across the world now.

This leads Gore into a consideration of the roots of the problem, in particular the main sources of greenhouse gas emissions. Some striking graphics visually emphasize the large contribution to greenhouse gas emissions made by the U.S. Gore points out some of the global inequities in consumption that have led to this situation and militate against any remedial action. He identifies energy production as the main culprit and highlights the need to move to alternate energy sources, such as wind power. Here, the text gets more overtly political with Gore taking aim at the Bush administration for obfuscating the issue and refusing to act, for example, by not ratifying the Kyoto Protocol.

Interspersed within the text are eight short essays, most of which recount anecdotes and incidents from Gore's life. These stand out from the rest of the narrative by being printed in smaller font on tan-coloured pages. The essays highlight some of the reasons for his passionate concern about global warming. What they show is that this is not a recent preoccupation but something that has engaged his attention for many years, growing out of life-long interest in environmental issues. Clearly, he wants to let readers know that he is not simply "jumping on a bandwagon" and taking up a trendy issue out of opportunism, but is following an interest that has underpinned his political career. Here, I did feel that I was reading a political manifesto at times. There's a lot of name-dropping and there are rather too many "warm and fuzzy" pictures of Gore and his family for my taste. Nevertheless, these essays bring the issue from the abstract to the personal, which does sharpen the sense that these concerns matter to individuals. By being set off from the rest of the text, it is clear that the message in these essays differs from the rest of the book.

The final section of the book, offset by being printed on light-green paper, is the call to action, outlining some things that individuals can do to make a difference. Most of these actions will already be familiar to most readers: buy a hybrid car, bag your groceries in re-usable shopping bags, replace incandescent light-bulbs with compact fluorescent bulbs, and so on. Generally, these actions are an appeal to a sense of guilt in affluent people living in western countries, where, Gore maintains, most of the problem originates anyway. Some of the suggestions run counter to many driving forces in the economy. When the TV screen is filled with ads encouraging us to be tourists and travel to sunny beachside resorts, how realistic is it to tell people to reduce air-travel? Interspersed among these exhortations are ten common misconceptions about global warming and Gore's recommended responses. These misconceptions include the ones you might expect, such as the assertion that "it's all just natural variation", though there was one I hadn't heard before, attributing global warming to after-effects of the Tunguska event.

In such a brief statement of the global warming issue, Gore obviously does not get into any topic in detail. There's clearly a lot more that could be said about all lines of evidence he presents but, unfortunately, there is no reading list for readers to follow up on any topics raised in the book. Nevertheless, Gore does assemble a persuasive argument that global warming is a problem and we need to do something about it immediately. However, this is very much a book that is "preaching to the converted". I can't see many people who are not already convinced there is a problem reading it. On the other hand, Gore is a well-known figure so perhaps some people may take a look at this book because of name-recognition. As a politician, Gore has to overcome a good deal of cynicism in order to reach people. This is a pity because this book is an articulate and thought-provoking presentation of a global phenomenon that affects us all.

MISCELLANEOUS

Gilbert White: A Biography of the Author of *The Natural History of Selborne*

By Richard Mabey. University of Virginia Press, Charlottesville. 2006. 239 pages. U.S.$16.50 Paper.

In his introduction, Mabey admits that, at his first reading of Gilbert White's *The Natural History and Antiquities of Selborne,* he could barely cope "with its rambling disorder." Only on visiting Selborne in person did Mabey change his view decisively. I marvel, as Mabey did, that White "could produce something so wholly original and appealing out of such unpromising ingredients."

In this Whitbread Prize-winning biography, the painstaking research of Mabey – whom the *Times* has called 'Britain's foremost nature writer' – results in a remarkably detailed account of the life of Gilbert White. Born in the tiny village of Selborne, White obtained his university education in theology at Oriel College, Oxford, beginning in 1739. Here he met John Mulso, in the year behind him. Although "constitutionally lazy and hypochondriacal," Mulso's life-long correspondence to and from White became a major source for Mabey. Perhaps it was equally providential that White was not particularly successful in his first three appointments to curacies at a distance from his home. When he returned to Selborne he began, somewhat inauspiciously, to commit his nature observations to paper in 1756.

White was patient and inquisitive. His early description in 1761 of the life of crickets was both "vivid and sensuous." In 1767 he began writing to the naturalist and author, Thomas Pennant; two years later he began his original observations that helped prove that birds migrate. In 1774, White's lively letters to Sir Daines Barrington included one about house martins, which Barrington read to a meeting of the Royal Society. The result was publication of these "models of lucidity and insight" in Britain's earliest scientific journal, *Philosophical Transactions.*

Finally, late in 1788, at age 68, White had the satisfaction of seeing his book in print. He died in June 1793, a month short of his 73rd birthday, modestly unaware of the prominence his book would achieve in the centuries to come. Second and third editions did not appear until 1802 and 1813, respectively, but there have been more than two hundred subsequent editions, one of the most published books in the English language.

I appreciated Mabey's delightful biography all the more because I, too, have visited Selborne. By learning more about Gilbert White, we can better appreciate White's impact on all subsequent nature writing. I congratulate the University of Virginia Press for making this inexpensive reprint, first published in hard cover in 1986, readily available to North Americans. I heartily recommend it to anyone with the slightest interest in English literature or the history of natural history.

A Paddler's Guide to Quetico and Beyond

By Kevin Callan. 2007. The Boston Mills Press, Erin, Ontario Canada. 192 pages. U.S.$24.95 Paper.

It's the dead of winter on a Friday evening when friends lay out the maps on the floor in front of a burning fire. Over wine, possible routes are discussed and commitments are made for a canoe trip six months hence into one of the most intact, accessible and largest protected wilderness areas in North America: Quetico Provincial Park. This is a book that will lead you beyond your usual canoe routes; in fact, it may inspire you to plan a trip celebrating Quetico's 100th anniversary in 2009!

Kevin Callan is no stranger to writing books on wilderness canoeing with seven "Paddler's Guides" for Ontario canoe routes to his name. Kevin reminds us that there is a great story to be told after every canoe trip we make, as a result of spending quality time with a group of family or friends on a journey through the natural world of wind, water, wildlife and plants, complete with portages, bannock and fireside stories. Each of the sixteen canoe routes described in this book is a well-written informative story, weaving important practical information such as the take-out and put-in spots for portages, special sites to see, and danger spots – into historical accounts of those who were here long before our forays using Kevlar canoes and Gortex. The stories also convey the hardships and joys shared by the group traveling with Kevin; the "real stuff" that makes canoe trips memorable.

The book does not overwhelm the reader with unnecessary detail on the gear to bring, what kind of canoe paddle is better than another, etc., rightly assuming someone heading to Quetico is not a novice. At the same time, simple, straightforward descriptions of canoe routes make them immensely doable for the average paddler. Exceptional pictures and tidy maps are also included, with references for the "proper" maps a canoeist must purchase in order to undertake these trips

Sixteen canoe routes are described in *Quetico and Beyond*; eleven in Quetico Park and five within neighboring areas of northern Ontario. Most routes require about one week to complete, although some are as short as 2-4 days and others as long as 28 days. Summaries provided for each of the canoe routes includes

number of days required to complete the route, the number of portages, the longest portage, route difficulty, access points, and the maps needed. Scanning the summaries provides a quick method to narrow down which routes look the most interesting within the time frame and abilities of the group.

Quetico is a book that provides very readable pleasant conversation that, in a personal way, brings canoeing to life through its past and more recent adventures. The many reminders of the subtle rewards of canoeing that are conveyed provide a real enticement to begin planning your next trip.

More than Kin and Less than Kind: The Evolution of Family Conflict

By Douglas W. Mock. 2004. Belknap Press of Harvard University Press, Cambridge, Massachusetts, USA. 267 pages. U.S.$27.95.

If you wish to understand how complicated and how variable reproductive behaviours can be, this is the book! Doug Mock offers a wide vista of nature in all its infinite variability and complexity. To explain bird behaviour, Mock invokes human examples, as diverse as his three older brothers, chess, Wall Street, sports teams, and vote counting.

Mock offers creative chapter headings and begins each chapter with a brilliant quotation. He simplifies difficult-to-understand concepts in an instructive and often entertaining manner. As he says, this book is a "mixture of theory and data." He is especially interested in brood size and in siblicide. I will offer a few highlights, some of which mention Canadian research.

Mock attempts to explain both the "hows" and "whys" of concepts that include Darwinian fitness, evolutionary game theory, inclusive fitness theory, evolutionarily stable strategy, parent-offspring conflict, parental manipulation, optimal clutch size, replacement offspring, and the insurance egg hypothesis.

Reproduction is costly. When Collared Flycatcher broods were enlarged artificially, there were fewer breeding adults the following season, and when two eggs were removed, females laid larger clutches the following year. Seychelles Warblers produced 77% male chicks in poor habitat and 88% female chicks in good habitat.

Lifetime monogamy is uncommon among birds but there are notable exceptions. A sample of 919 pairs of Bewick's Swans showed not a single divorce, but if a mate died the survivor would re-pair. From a sample of over 6 000 banded birds, 99.6% of Barnacle Goose pairs were socially monogamous.

Mock discusses Hamilton's rule, promulgated in 1964, whereby "two full siblings should be the evolutionary equivalent of one Self" – or eight cousins – based on the amount of shared genetic material. Altruistic behaviour, such as nest helpers, relates to the mix of relatedness.

What happens in nature often seems counter-intuitive if not outright bizarre. Biologists have difficulty understanding, much less explaining, such events. What conceivable evolutionary advantage could result from a surplus egg or surplus young? Why do some species of eagle and pelican regularly lay two eggs, yet raise only one young? Why does a parent bird passively watch one of its nestlings kill another, even when surplus food is within reach? Why does a hawk nestling sometimes eat its sibling after killing it, but on other occasions does not?

At Delta Marsh, Manitoba, Spencer Sealy videotaped nests with a single cowbird and a single warbler; the cowbird out-hustled, out-begged and out-stretched its warbler nestmate. In British Columbia, Bruce Lyon studied American Coots, which lose some chicks to starvation in nearly half the broods. Adult coots make a point of getting more food to the youngest, but when Lyon clipped the bright ornamental plumage of the tiny chicks, the clipped birds survived less often.

The late Roger Evans of the University of Manitoba did experiments to study the role of the extra or "insurance" egg in the American White Pelican. He and his student Kevin Cash carefully marked the first-hatching or A egg, and the second-hatching or B egg. Twenty percent of the B eggs hatched. The parent pelican would brood its young, but as soon as the parent stood up, the older young attacked its smaller sibling.

Wahlberg's Eagle, which ranges across central Africa, lays a single egg; not more than three percent of pairs lay a second egg and then the larger chick regularly kills the smaller one.

The Verraux's (Black) Eagle lays two eggs, but an observed first chick began assaulting the second chick soon after it hatched, giving 1 569 blows with its beak to kill its sibling, even though food was plentiful in the nest. The Crested Penguin lays two eggs, but the first egg is up to 40 percent smaller; four days later the second, larger egg is laid and is given the optimal brood patch position beneath the mother, and is usually the sole survivor.

Mock does not restrict himself to birds. He writes about plants, insects and fish, using the firefly as an example of signalling. He tells how, in a pig litter, anterior teats produce more milk than posterior teats, hence the colloquialism, "sucking hind teat."

As Marlene Zuk says on the dust cover, this book about family conflict "is a model of how behavioral ecology can and should be done … Just don't take it to family reunions."

To See Every Bird on Earth

By Dan Koeppel. 2005. Hudson Street Press, New York, New York, USA. 278 pages. $24.95 U.S.$35.

Dan Koeppel tells the story of his father, Dr. Richard Koeppel, a chronically unhappy medical doctor with two overwhelming obsessions: to see as many species of birds as possible, world-wide, and to read, cover to cover, every novel that was short-listed for or won the Booker Literary Prize.

Each chapter begins engagingly with a postage stamp that features a bird from the collection of Chris Gibbins who has amassed stamps depicting 2950 species (a record list!), and a paragraph from Richard Koeppel's notebooks telling of a numbered addition to his life-list.

One learns about the methodology of listers, particularly the rules laid down by the American Birding Association (pages 195-197). Dan explains, in layperson's terms, "lumping" and "splitting" of species. Despite the ever-escalating CPB (cost per bird), Dan fully realizes that the listing process is "intensely arcane, fascinating, and absurd."

This is a quick and easy read, but in no way uplifting. Dan's brutally frank, very personal psychoanalysis of his father and mother is somewhat excessive and distracting. Dr. Richard Koeppel, it seems, entered medicine to please his parents, and sadly failed to find a fulfilling niche in medicine. His marriage failed early. He became a morose, rather pathetic man who found solace in excessive use of marijuana, alcohol and nicotine. Most of his career was in emergency medicine, where roughly half his time could be spent birding. When his bad habits caught up with him in the form of larynx cancer, Richard Koeppel's personal list was at 7080 species.

I most enjoyed the behind-the-scenes accounts of Jim Clements, who compiled the first one-volume list of birds of the world, and has amassed a personal life list of 7200; Victor Emmanuel, who began the first field trips designed to add maximum numbers of birds to each customer's life-list; and Bret Whitney, who lacks formal postgraduate education in ornithology but has succeeded the late Ted Parker as a finder and describer of new species in South America.

One also meets Richard's competitors. Within our region, North and Central America, Dan Canterbury has seen a record 1731 species. Peter Kaestner, who traveled widely in the diplomatic service, was the first person to have seen a representative of all 159 avian families. Others in competition with Richard Koeppel for the world list have been Harvey Gilston of Britain, who, without ability to identify the bird himself, would check off a bird when a guide called out its name (he reached nearly 8000); Michael Lambarth and Sandra Fisher of England (Michael quit when his beloved partner died); Joel Abramson, a medical doctor who hired top birders to lead endurance-test expeditions; Stuart Keith, founder of the American Birding Association, who was recognized by the Guinness Book of World Records when his list reached 4300; Roger Tory Peterson, who reached the "half-way total" of 4800 in the 1980s; Bill Rapp, nearing 7000; Jim Plyler, a retired oil executive at 7200; Peter Winter and John Danzenbacker, military men, at 7800 and about 7750, respectively; Peter Kaestner, with 7958; Tom Gullick, leader of those still alive, with 8114; Phoebe Snetsinger, still tops, who reached nearly 8500 before she died in a car accident in Madagascar in 1999.

What are the downsides to this book? The title is a bit misleading, since Dan Koeppel knows full well that no human will ever see every bird (of about 9600 species) on earth. An index to birder's names would have been helpful. Worse, Richard Koeppel, the protagonist of this story, is a sad and pathetic person, lacking enthusiasm for his profession, with complicated marital and family situations. He is a perfectionist but only on rare occasions does he show much feeling, even for birds. But Richard has made amends with his son, Dan, and has recently turned his attention to butterflies.

All readers of this review, especially the writer, are sinners. We claim to be environmentalists, yet many or perhaps most of us drive gas-guzzling vehicles to pursue our sometimes obsessive hobby. At least we fall short of the obscenely high travel expenses of certain of the Big Listers.

Wildfire in the Wilderness

By Chris Czajkowski. 2006. Harbour Publishing, Madeira Park, British Columbia, Canada. 221 pages. $19.95 Paper.

A woman who lives a solitary life in the wilderness of the British Columbian mountains, dozens of kilometres from her nearest neighbours, has not isolated herself from her community. Her life is a heart-warming set of tales explaining the connection she has to the community of mountain dwellers, outfitters, and bush pilots in her immediate neighbourhood as well as friends, publishers, fans of her books and international tourists in the wider community. The reader is introduced to her dogs, her history of publications, her ingenuity in building and maintaining a wilderness site and even the state of her bank account while following her stories of maintaining solitude in the mountains and contacts with the outside world.

A hiker, camper and outdoorsman would certainly relate to Chris Czajkowski's stories and her descriptions

which make the mountains a home. The well-being of the environment becomes close to the heart of any dweller of the wilderness and the threat of nature taking a turn for the worst can send dwellers of the backwoods to worry over their personal charge, the nature and landscape around them. Sustained inclement weather, freak storms, too much snow in a season, frost at the wrong time, drought in the wrong season or prolonged drought in any season, are all causes for worry but a natural disaster like a wildfire is feared above all. Though the title tells us only of one dramatic event in the history of her lake, cabins and near environment, the reader is drawn into her whole lifestyle of protecting, nurturing and living within the environment which she has come to call home.

As the story unfolds, Czajkowski leads us into her world, travelling long distances, keeping up with modern technology, camping and hiking with her tourist helpers. She is home in her particular isolated part of the world a long way from her nearest neighbours but connected with them by regular radio conversations, listening to radio broadcasts and occasionally eavesdropping on her neighbours' conversations, and finally email as that technology became available. At the same time, she is host to the world by operating a small guest house for people willing to travel the distance to spend a few days with her, or international wanderers who pay by passing a few weeks working and helping her with projects.

Finally the reader is led to the hot dry summer of 2004 and the devastating fire, the Lonesome Lake Fire which was well reported to the Canadian public as one of many fires in a hot dry summer, but to people of that remote region, a disaster which shaped their environment for years to come. The reader is invited to travel with Czajkowski through the fear and uncertainty of watching gathering smoke and distressing news from various watchers in neighbouring valleys. We are inspired to evacuate with her to safer areas, but without any assurance that home or lifestyle could be preserved. Czajkowski leads us along her tale with interesting anecdotes and humorous stories about her dogs, friends, and people who come to visit her. She is an engaging story-teller and keeps the reader's attention for hours or just a few minutes at a time as the book is filled with short stories, portions of her diary and longer accounts of specific incidents.

The story builds in an entertaining way through her history of building the cabins, receiving visitors, including facts about making one's life in the wilderness at the same time maintaining connections firmly planted in the outside world. The fire is the high point of the book and gets the reader to the excitement of living her experience of the fear, doubt, loneliness and response of care for her own animals and the natural dwellers of her wilderness world. The reader enters into the story with her and can live the excitement she feels. In our sheltered world, our decisions are not always the same as the author's but she puts her concern and care for her environment in front of the reader and shows us a different world to enjoy for a little while then look forward, like her globe-trotting visitors, to the next visit we might have with her.

YOUNG NATURALISTS

Tale of a Great White Fish

By Maggie de Vries. Greystone Books, Douglas & McIntyre Publishing Group, Vancouver, British Columbia, Canada. 34 pages. $12.95.

The book *Tale of a Great White Fish* follows the story of a giant white sturgeon. Through its long life, the sturgeon overcomes many obstacles in its battle to survive and reproduce. The story deals with the interaction between sturgeons and people, along the way providing the reader with a wealth of information and insight into the natural history of the sturgeon.

The story starts in 1828, when the sturgeon, named "Big Fish," was a small and defenceless egg hatched in the Fraser River. She matures into a larva and then into a fry. As a fry she must eat thousands of other small water creatures to grow. Fry are also especially vulnerable to predators, and most of the young fry never reach adulthood. The fry that survive mature into adults before returning to their spawning ground to lay their own eggs.

There are many dangers that the sturgeon must overcome. For most of their long existence sturgeon have been around since the time of the dinosaurs, the threats have been natural: predators, natural calamities and disease. Today, human fishermen and the caviar industry are one of the greatest perils. Big Fish was hooked by a fisherman, but fortunately she was freed by some young boys and was able to escape. During the Hells Gate Slide in 1913 many migrating sturgeon were killed. Big Fish survived, but she was forced to find a new place to spawn. Later, Big Fish had to find a new home because the lake she was living in was drained. Later still, an unknown disease swept through the Fraser River and many sturgeon died and were washed up on the shores of the lake. When the story closes, almost a hundred years later, Big Fish is still surviving, but continues to face many challenges.

Scientists study sturgeons to help them survive. They keep track of their weight and size, and try to stop overfishing. There are now laws which prevent the fishing of these magnificent animals.

The book is written as a story and at the end there is a useful list of sturgeon facts, a labelled diagram of a

White Sturgeon, a glossary, and a letter from Rick Hansen, a famous Canadian para-athlete. Rick Hansen is the chairman of the Fraser River Sturgeon Conservation Society. The drawings by Renné Benoit are done in water colours and they provide a magnificent glimpse into the beautiful and dangerous world of the great White Sturgeon.

The book is very informative. In it, the reader will learn a great deal about the White Sturgeon's environment and behavior and appearance. The Sturgeon Facts and a glossary at the book of the book provide a very useful summary, and is well presented.

The book is aimed at a child's reading level. Older readers would find this book less interesting; however, it provides a basic insight into the world of a great white fish and is nicely illustrated. This book is recommended for any child with an interest in the outdoors and in nature.

Volume 3, Number 1, contains FROM THE EDITOR: Coming together — On the covers — FEATURE ARTICLE: Supplement to *Wildlife Afield*: Roads and wildlife — NOTES: American Avocets breeding at Bechers Prairie near Riskke Creek, British Columbia in 2005 and 2006 (Phil Ranson) — Manx Shearwater in British Columbia: comments on a pioneering seabird (Michael Force, Ken Morgan, and Jukka Jantunen) — A noteworthy record of the Pigmy Short-horned Lizard (Glenn R. Ryder, R. Wayne Campbell, and Lawrence Powell) — Cactus traps California *Myotis* in British Columbia (Christian W. Gronau) — Whip-poor-will *Caprimulgus vociferus*: a new species for British Columbia, 1968-2006 (Adrian Dorst) — Status of the Yellow-breasted Chat in the Creston Valley, British Columbia, 1968-2006 (R. Wayne Campbell and Edward McMackin) — Unusual mortality of a male Rufous Hummingbird in Burton, British Columbia (Arthur Schoeddert) — Common Raven steals and caches eggs of the Double-crested Cormorant in the Creston Valley, British Col-

umbia (Linda M. Van Damme) — Impact of Cooper's Hawk predation on a nesting colony of Brewer's Blackbirds on Vancouver Island, British Columbia (R. Wayne Campbell and Barbara Begg) — Golden Eagle attacks and kills yearling Mountain Goat (Barbara Zettergreen) — Skeletal remains of the Northern Flicker with a gross bill deformity discovered in a popular tree cavity (Sherry L. Lidstone) — WILDLIFE DATA CENTRE: — Featured species — Common Nighthawk (R. Wayne Campbell, Martin K. McNicholl, R. Mark Brigham, and Janet Ng) — Report of the Wildlife Data Centre: 1 January 2006 to 30 June 2006 (Michael I. Preston) — BRITISH COLUMBIA ROUND-UP: Tips for the field — Field notes for caring people — Errata — News of friends — Life membership — a personal commitment to wildlife — From the Archives — Final Flight — Announcements, Publications of Interest — Volume 3(1), (and Supplement to 3(1), contains: FROM THE EDITOR: At a crossroads — On the covers — ROADS & WILDLIFE: Collisions with wildlife: An overview of major wildlife vehicle collision data collection systems in British Columbia and recommendations for the future (S. Gayle Hesse) — A comparison of roads and rivers as barriers to animal movements: implications for roads in protected areas (Joanna Preston) — High incidence of vehicle-induced owl mortality in the lower mainland and central Fraser Valley, British Columbia (Michael I. Preston and Gerry A. Powers) — A study on the incidence of amphibian road mortality between Ucluelet and Tofino, British Columbia (Barbara Beasley) — Mitigation efforts to reduce mammal mortality on roadways in Kootenay National Park, British Columbia (Michael I. Preston, Larry Halverson and Gayle Hesse) — Using wildlife vehicle collision data, expert opinion and GPS technology to more accurately predict and mitigate vehicular collisions with wildlife in northern British Columbia (Roy V. Rea, Eric K. Rapaport, Dexter P. Hodder, Michael V. Hurley and Nicole A. Klassen) — Road watch BC: A program for collecting, centralizing, and synthesizing information from vehicle-induced wildlife mortalities in British Columbia (R. Wayne Campbell and Michael I. Preston) — Estimating the probability of potential vehicle collision from birds cross roads in interior British Columbia (Michael I. Preston and Joanna Preston) — USEFUL RESOURCES: Books — Symposia, Proceedings, Handbooks, and Reports — Websites — Upcoming meetings — Book review: Road ecology — Road watch BC — Wildlife collision prevention: Hints for the highway.

Details on membership can be obtained from the Biodiversity Centre for Wildlife Studies, PO Box 6218, Station C, Victoria, British Columbia V9P 5L5 Canada. Tel/Fax: 250-477-0465; e-mail: editor@wildlifebc.org; web site: www.wildlifebc.org.

Errata *The Canadian Field-Naturalist* 120(2)

Table of contents outside back cover:
Conservation evaluation of Dwarf Wolly-heads, *Psilocarphus brevissimus* var. *brevissimus*, in Canada
GEORGE W. DOUGLAS, JENIFER L. PENNY, and KSENIA BARTON
"Wolly-heads" should read Woolly-heads.

Article page 235:
First record of a River Otter, *Lontra canadensis*, captured on the northern coast of Alaska
SHAWN P. HASKELL
In abstract and citation "*Lutra*" should be *Lontra*.

Errata *The Canadian Field-Naturalist* 120(3)

Table of contents outside back cover:

Recent invasion, current status, and invasion pathway of European Common Reed, *Phragnites australis* subspecies *australis*, in the southern Ottawa District
PAUL M. CATLING and SUSAN CARBYN
"*Phragnites*" should read *Phragmites*.

Pacific Hagfish. *Eppptatretus stoutii*, Spotted Ratfish, *Hydrolagus colliei*, and scavenger activity on tethered carrion in subtidal benthic communities off western Vancouver Island
SARAH DAVIES, ALI GRIFFITHS, and T. E. REIMCHEN
"*Eppptatretus*" should read *Eptatretus*

The Ottawa Field-Naturalists' Club Awards for 2005

Irwin M. Brodo, Christine Hanrahan, Beverly McBride, and Eleanor Zurbrigg

At the Club's Annual Soirée, held on 29 April 2006, at St. Basil's Church in Ottawa, awards were once again given to members, and two non-members, who distinguished themselves by accomplishments in the field of natural history and conservation, or by extraordinary activity within the Club. For the first time in several years, we had a recipient of the Anne Hanes Natural History Award, and the Mary Stuart Education Award was given for the second time. The following citations for those who received an award were read to the members and guests assembled for the event.

Gillian Marston and Suzanne Deschenes – Members of the Year

The OFNC's Member of the Year award recognizes the member(s) judged to have contributed the most to the club during the previous year. Education and Publicity Committee members Gillian Marston and Suzanne Deschenes have made stellar accomplishments over the past year in developing educational and publicity materials for OFNC, and leading a successful membership drive through publicity efforts. They have also brought their considerable computer skills to modernize the Club's photo library and displays.

Gillian and Suzanne are the driving force behind the OFNC's new photography contest which began in 2005 and is set for a second round in 2006. Meant to encourage people's appreciation of nature through photography, and to boost the club's library of digital photographs on natural themes, the first contest reaped 275 images, all of which have the potential to be used in displays or slideshows. The contest resulted in a professional, stunning slide show for the 2006 Annual Business Meeting. All these new images are now catalogued in a digital library, also developed and managed by Suzanne and Gillian. This library is the successor to the club's long-standing and well used slide collection.

Suzanne and Gillian together bring a special synergy of creativity and management skills. They further applied their talents in 2005, taking the club's new image collection to the public by designing and constructing several portable exhibits to highlight Ottawa nature, the club's activities, and to attract new members. Members and non-members alike will recall seeing volunteers staffing these exhibits at the entrance to popular nature walk areas such as the Britannia Conservation Area. They also appeared on site for various club excursions and conferences where they successfully attracted a good number of new members and caught the eye of educators. Gillian and Suzanne and the rest of the committee continue to develop more portable exhibits and to refine the design. For example, they put together a set of slide shows on different themes that can be shown at exhibits using a table-top projector or laptop computer.

Gillian and Suzanne, the club is grateful for your many special contributions during 2005. Designating you as members of the year is our way of saying "thank you"!

Christine Hanrahan – George McGee Service Award

Most successful organizations have a handful of members that devote themselves, body and soul, to the workings of the group, serving on committees, on Council, and in any way that they are needed to make the Club succeed. Christine Hanrahan is one of these people. The Ottawa Field-Naturalists' Club has benefited from her efforts and devotion for over 25 years, and we recognize these efforts with the George McGee Service Award. This award honours members who have volunteered their time to the betterment of the Club over several years. The award commemorates George McGee, who for more than three decades actively devoted much of his spare time to teaching people about birds and natural history through his talks and numerous outings.

Christine has been a member of the OFNC since the late 1970s. She has been an active member of many Club committees, including the Fletcher Wildlife Garden Committee, Conservation Committee, Bird Committee, and Awards Committee. On top of this, she has recently coordinated the local group working on the Ontario Breeding Bird Atlas, which is now drawing to a close. Co-ordinating over a hundred volunteers for 5 years (plus an additional start-up trial year, plus the final data compilation/coordination in 2006) is no small feat. Not only was there all the coordination between Atlas headquarters and the region's 24 volunteers, which included distributing information packages, forms, CDs and other material, but also there were the annual meetings to coordinate, the annual reports to write, the articles for *Trail & Landscape*, and hours and hours spent on-line writing e-mail messages and checking the data of the central database. And this is the *second time* Christine has done this! She was the lead

coordinator in region 24 for the first Atlas project 20 years ago. After that she coordinated the Loggerhead Shrike survey in this area.

But our members probably know Christine best through her work on the Fletcher Wildlife Garden Committee over many years. She has diligently kept long-term and short-term lists of many of the FWG occupants and visitors (e.g., birds and butterflies). This includes preparing the current sightings board and the checklists. She has published many articles in *Trail & Landscape* about the activities and happenings at FWG. She has prepared posters, many pamphlets, checklists, nesting reports, etc., if not solely, then as the main driving force. She has organized many important activities at the Centre to draw in and educate visitors. Every year she has prepared the FWG display and organized the hosting (including herself) at the National Capital Region Wildlife Festival. She has also prepared displays at other events such as the Health Canada-sponsored Environment Day.

Christine has represented the OFNC and the FWG on the National Capital Wildlife Festival Committee for many years and puts a huge amount of time into organizing workshops and conservation awards. The workshops she has organized have been on topics of great interest to the OFNC, such as Invasive Alien Species, conservation (Protecting Wild Places) and bird conservation.

Another of Christine's favourite activities is the OFNC Conservation Committee. She has participated in many committee activities and battles including, most recently, the Larose Forest issue. Here she worked on developing checklists of the flora and fauna with various specialists. She also worked for hours and hours with Ghislaine Rozon reviewing documents, preparing strategy, briefs, writing letters, attending all kinds of meetings in an effort to save the forest from development. Her work on conserving Petrie Island also had a major impact. Working with The Friends of Petrie Island, she compiled lists, wrote articles for *Trail & Landscape*, organized field trips, as well as attending endless meetings, reviewing documents, and preparing OFNC responses. There have been many other conservation issues around Ottawa that have received Christine's attention and hard work, including: Moffat Farm, Montfort Woods, Nortel Woods, Leitrum wetlands, 5309 Bank Street (Tomlinson quarry) and Ferguson Forest. The list seems endless.

And who among us has not read, enjoyed and learned from Christine's many articles in *Trail & Landscape*. She has published on birds, plants, habitats and a wide range of conservation issues. Her short article on snags and old logs is a well known, authoritative and influential document. It has been reproduced and widely distributed within the Ontario Ministry of Natural Resources and has been used and cited by people even in other parts of the world. Her article on hedgerows and their importance to wildlife is another gem and has become an important resource for ecologists. Since the OFNC has been on the Internet, Christine has been an active contributor to our website with informative and interesting material on a variety of natural history subjects.

Because Christine has also served as a knowledgeable member of the Awards Committee for a number of years, recognizing all her achievements and work with an appropriate prize "slipped through the cracks". Not until her nomination came from outside the committee by a number of members all wondering how she could have been overlooked so long could we make this presentation. The Club is therefore pleased to present Christine Hanrahan with this long overdue and well-deserved Service Award.

Friends of the Carp River – Conservation Award (Non-Member)

The OFNC Conservation Award, non-member, is given to a group or individual who has made an outstanding contribution in the cause of natural history conservation in the Ottawa Valley, with particular emphasis on activities within the Ottawa District.

The Friends of the Carp River have worked for many years to protect and restore the ecosystem of the Carp River, and this dedication makes them very worthy recipients of this award.

The Friends of the Carp River grew out of the West Carleton Township's Environmental Advisory Committee which began an extensive study of the Carp River in 1993. The organization was formed in 1997 as a citizen's group whose goal was to help restore and improve the health of the Carp River. The river has its headwaters just south of the Corel Centre and flows 42 km to the Ottawa River at Fitzroy Harbour, and is "the only river that flows entirely within the boundaries of the City of Ottawa". Over the years the river has suffered from shoreline erosion, siltation, flooding, low oxygen levels and subsequent loss of important wildlife habitat. Working with various groups, including landowners, businesses, government agencies and recreational users, the Friends are developing some substantial, achievable goals to continue rehabilitating the "ribbon of life", their wonderfully descriptive term for the Carp River.

Studies show that the Carp River has suffered overall degradation, including silting problems due in part to agricultural tilling practices and channelization. Shoreline erosion further contributes to siltation, which puts at risk the 40 species of fish inhabiting the river. Tributaries of the Carp River have severely degraded water quality due largely to agricultural fertilizers and animal wastes. In spring 2006, the threat of development in the floodplain could bring more problems such as future flooding as well as damaging restoration projects.

The Friends of the Carp River, an entirely volunteer-run organization, is dedicated to reversing the decline

of the river and the Friends have already made tremendous improvements. The Friends have planted over 20 000 trees and shrubs since 1997 with the help and cooperation of local landowners living along the river and many volunteers, and this will have a substantial positive impact on controlling erosion and siltation. With assistance from provincial foresters, site plans for tree planting have been created.

The Friends have worked with the City of Ottawa on its Watershed study, and gathered support from the Ottawa Stewardship Council and the Rural Clean Water Program. Their work was recognized with a Trillium Foundation grant of $50 000 to help them achieve their goal of rejuvenating the Carp River. One of their objectives for this grant was to commission a study of the river, which they did, and the *Carp River Remediation Project report* was prepared by consultants in April 2003.

The Friends of the Carp River have produced a pamphlet which details ways and means for landowners to achieve best management practices. The Friends are available to help steer farmers and others to specific programs, including funding, to enable them to implement improvements that benefit both landowners and the river.

The Friends have been ingenious, creative and tireless in coming up with ways to garner support for the river. Believing that an "image change" for the river was a necessary part of creating a positive public perception, they held a year-long photography contest that encouraged people to submit photos of the Carp River, and also persuaded them to look at the river as a thing of beauty . Winning entries were used to create a Millennium calendar, *Flowing into the next Millennium: A year in the life of the Carp River*, which was sold at cost and sold out in three months. The photos were also used to create sets of notecards, again sold at cost.

A benefit concert with Terry Tufts and Kathryn Briggs was held on Earth Day, 2001 to help raise funds for continued work on the river. A CD of a song, *The Mighty Carp* by Dan Mayo, inspired by the river and dedicated to the Friends was released in 2002.

The Friends explain that "shorelines are breeding grounds, nurseries, food sources, shelter, and hiding places for many species. Ninety per cent of all living things in a lake or river are found along the shoreline. Shorelines are effective natural filters and buffer zones, acting as the 'kidneys' for the watershed. Shorelines help to improve the quality and quantity of ground water. Polluted run-off is trapped and absorbed by the vegetation, thus protecting water quality. The complex interplay of plants, animals, land, and water combine to make the shorelines the single most important part of the river ecosystem."

The Friends have been remarkably successful in drawing the community into active involvement with the health of the river as evidenced not only by the many volunteers who turn out for tree-planting activities but by the tremendous support they have received from local businesses and granting agencies. For these reasons and more, the OFNC is very pleased to give the Friends of the Carp River this year's Conservation Award for non-members.

Iola Price – Conservation Award (Member)

The OFNC Conservation Award is given in recognition of a club member who has made an outstanding contribution towards protecting our natural environment. Iola Price is a very worthy recipient of this award in recognition of her effective membership in the City of Ottawa's Forest and Greenspace Advisory Committee (OFGAC) to promote conservation of trees and forests.

As the current Chair of the Ottawa Forests and Greenspace Advisory Committee, and co-chair before that, Iola provides an articulate and credible voice on issues related to conservation of the trees, forests and greenspace of our Nation's capital.

The Ottawa Forests and Greenspace Advisory Committee was established in the fall of 2001 to advise Ottawa City Council and provide a forum for citizens on issues related to trees and forests. Iola's accomplishments include reviewing OFGAC position papers before transmission to appropriate authorities, preparation of numerous written briefs and making powerful submissions to city committees. For example, Iola recently exhorted City Council at a budget planning meeting to "think of trees as green infrastructure, as essential to a well-ordered city as sewers, lighting and roads".

On many occasions, Iola has made a powerful and persuasive intervention during the City's planning process in support of the importance of greenspace and protection of sites of urban natural ecological significance. Her recent interventions regarding the Nepean Creek Corridor as well as her efforts for improving the criteria utilized for determining appropriate urban density development levels underscores this dedication towards the maintenance and protection of trees and greenspace in the National Capital Region (NCR).

Iola has provided recommendations to strengthen ecological provisions in urban design studies such as Riverside South Community Design and Leitrim Community Design. She spearheaded opposition to development projects such as the highly controversial Carp Ridge housing project and the Phase 2 Leitrim Wetlands development, which, if approved, would extend housing into the wetland itself.

Iola is recognized as a very effective and valuable "networker", regularly liaising with other tree and greenspace-oriented community groups operating in the NCR. This includes our Club through the Conservation Committee and Fletcher Wildlife Garden. Members of these committees wholeheartedly appreciate that Iola

is very quick and efficient in replying to queries and in exploring issues and ideas, which helps so much when it allows one to continue one's work without delay.

Through this award, OFNC members recognize the outstanding efforts towards protecting our natural environment by one of our members – Iola Price.

Macoun Field Club – Anne Hanes Natural History Award

The Anne Hanes Natural History Award, named in honour and memory of one of the Club's most dedicated amateur naturalists, is made in recognition of a member who, through independent study or investigation, has made a worthwhile contribution to our knowledge, understanding and appreciation of the natural history of the Ottawa Valley. The award is designed to especially recognize work that is done by amateur naturalists.

The OFNC feels that there can be no more worthy recipient than the Macoun Field Club in recognition of the remarkable studies the members of the MFC have made of the Macoun Study Area in Bells Corners over a 35 year period, documenting rare plants and animals, tracking changes to plant and animal populations as well as the environment, producing and up-dating vegetation maps of the area, and much more. The MFC, sponsored jointly by the OFNC and Canadian Museum of Nature, has been a haven for youngsters interested in nature since 1948, and accepts members from grades 4 through 12.

The idea of having a special area of natural land designated as a "study area" for members of the Macoun Field Club came from the senior (high school) members, not from the adult leadership. The first study area in the Bells Corners area was actually where the Wild Bird Centre is now, but because the OMNR was cutting out the dead and dying elms at the time, they suggested an area across the road in a less disturbed site west of Moodie Drive. Within two years, the members had drawn a vegetation map of most of the 800 acres making up the site. This valuable base map was based on aerial photographs supplemented by field trips to determine what was there. There have been several versions made to keep pace with changes: 1972, 1986, 1992, and 2000. A colour version was created for the Club's web site (www.magma.ca/~rel/mfc/studyarea/msa.html). In this way, the MFC members traced the changes that occurred in a significant part of the Ottawa Greenbelt brought on by urbanization, beaver activity, tree diseases and people. The MFC members, on their bi-weekly field trips over many years, mostly led by Rob Lee, created lists of trees (54 species), wildflowers, birds, mammals (29 species), reptiles and amphibians, and lichens (215 species). In the process, they discovered many rarities and have documented the disappearance of certain species. Their studies continue on everything from "the sand grains in the soil" to "Leatherwood Treehoppers."

Because each member is encouraged to "adopt a tree" and study its growth and health, its inhabitants in the crown, on the trunk and at its base, the MFC has amassed an amazing amount of information about seasonal fluctuations in a suburban forest system.

Much of this information has been organized on the MFC's amazing website designed and maintained by Rob Lee, but the information itself was gathered by the members. It is improbable that any urban greenspace in Canada has such a well-documented history of its flora and fauna.

Observations on the Macoun Study Area have been regularly published by the members in their annual magazine, *The Little Bear*, and, because of the Internet, is now readily available to the general public as well. Most important, the experience that the members have gained in doing careful field research has encouraged many past members to embark on a career in conservation biology, botany, zoology, park management or teaching.

The OFNC feels that the Macoun Field Club members have done a remarkable job, under the leadership of Rob Lee, and well deserves the Anne Hanes Natural History Award.

Michael Léveillé – Mary Stuart Education Award

The Mary Stuart Education Award was established to recognize members, non-members or organizations for their outstanding achievements in the field of natural history education in the Ottawa Region. Michael Léveillé, a science teacher at the Educarium, an Ottawa private school, is without doubt a natural history educator par excellence, and a most worthy recipient of this Award.

Michael has taught at the Educarium since 1996. His passion for nature is infectious and inspirational and is observed most keenly by his students. Michael brings an impressive background to his role as science teacher. He founded the Ottawa Paleontology Society in 1991 to advance an understanding of fossils. He has long been associated with the Canadian Museum of Nature where he created a number of popular programs, most notably the "Collector's Corner", a museum discovery centre. At the museum he worked with people of all ages, instilling an awareness of, and appreciation for, the natural world. However, there is no doubt that Michael excels at working with young people, encouraging them to be attuned to the rhythms of the natural world around them.

Michael is also an accomplished artist with a degree in Visual Arts from the University of Ottawa. His work has been exhibited at local universities, museums, as well as at the Educarium. Michael was the artist for the children's storybook series "Fergi the Frog".

Under Michael's knowledgeable direction, in 2004 his students designed and implemented the "Macoun Marsh Project" at Beechwood Cemetery, to demonstrate how a thriving and diverse ecosystem can exist inside a large urban centre. This became one of their most ambitious and high profile projects, and is ongoing. Because the marsh was unnamed when they began working on it, they held a "Marsh Naming Contest" and encouraged neighbours and the community at large to join in. Overwhelming support led to naming it after John Macoun (1831-1920) who is buried at Beechwood. The contest, and the work done by the students, led to increased public awareness of the site and eventually resulted in the Directors of Beechwood Cemetery making a firm commitment to protect and maintain it.

The Macoun Marsh project encourages students to study the marsh over different seasons. They are taught to record scientific observations in journals, identify and study the different species found, and learn the fundamentals of ecology. They also design, construct, install and maintain bird feeders at the site. Under Michael's careful instruction, the Educarium students have documented nearly 900 species at the marsh.

The project has grown beyond their wildest expectations. Funding to continue with studies and enhancements has been obtained from a variety of sources including the Wetland Habitat Fund and the City of Ottawa. In conjunction with the Beechwood Cemetery Foundation, plans are underway for habitat enhancement, a boardwalk, and an outdoor classroom in spring 2006. The students continue to keep nature journals and will present this work at various venues around the city over the coming year. Michael invited the neighbouring Jean Vanier Catholic School to join his students on the project, and in May 2006 both schools sent representatives to Göteborg, Sweden, for the Volvo Adventure International contest for natural history projects.

Michael's inspired teaching guarantees that his students will continue to be engaged by the world of nature, and so it is for this most important work, that OFNC is pleased to present Michael Léveillé with the Mary Stuart Education Award for 2005.

Advice for Contributors to *The Canadian Field-Naturalist*

Content

The Canadian Field-Naturalist is a medium for the publication of scientific papers by amateur and professional naturalists or field biologists reporting observations and results of investigations in any field of natural history provided that they are original, significant, and relevant to Canada. All readers and other potential contributors are invited to submit for consideration their manuscripts meeting these criteria. The journal also publishes natural history news and comment items if judged by the Editor to be of interest to readers and subscribers, and book reviews. Please correspond with the Book Review Editor concerning suitability of manuscripts for this section. For further information consult: A Publication Policy for the Ottawa Field-Naturalists' Club, 1983. *The Canadian Field-Naturalist* 97(2): 231-234. Potential contributors who are neither members of *The Ottawa Field-Naturalists' Club* nor subscribers to *The Canadian Field-Naturalist* are encouraged to support the journal by becoming either members or subscribers.

Manuscripts

Please submit by post **to the Editor,** in either English or French, **three** complete manuscripts **written in the journal style.** Manuscripts may also be submitted (one copy) by e-mail. The research reported should be original. It is recommended that authors ask qualified persons to appraise the paper before it is submitted. All authors should have read and approved it. Institutional or contract approval for the publication of the data must have been obtained by the authors. Also authors are expected to have complied with all pertinent legislation regarding the study, disturbance, or collection of animals, plants or minerals. The place where voucher specimens have been deposited, and their catalogue numbers, should be given. Latitude and longitude should be included for all individual localities where collections or observations have been made.

Manuscripts should be printed on standard-size paper, **doublespaced throughout,** generous margins to allow for copy marking, and **each page numbered.** For Articles and Notes provide a bibliographic (citation) strip, an abstract, and a list of key words. Generally, words should not be abbreviated but use SI symbols for units of measure. The names of authors of scientific names may be omitted except in taxonomic manuscripts or other papers involving nomenclatural problems. "Standard" common names (with initial letters capitalized) should be used at least once for all species of higher animals and plants; all should also be identified by scientific name.

The names of journals in the Literature Cited should be written out in full. Unpublished reports and web documents should not be cited here but placed in a separate Documents Cited section. List the captions for figures numbered in arabic numerals and typed together on a separate page. Present the tables each titled, numbered consecutively in arabic numerals, and placed on a separate page. Mark in the margin of the text the places for the figures and tables.

Check recent issues (particularly Literature Cited) for journal format. Either "Canadian" or "American" spellings are acceptable in English but should be consistent within one manuscript. **The Oxford English Dictionary, Webster's New International Dictionary** and le **Grand Larousse Encyclopédique** are the authorities for spelling.

Illustrations

Photographs should have a glossy finish and show sharp contrasts. Electronic versions should be high resolution. Prepare line drawings with India ink on good quality paper and letter (don't type) descriptive matter. Photographic reproduction of line drawings should be **no larger than a standard page.** Write author's name, title of paper, and figure number on the lower left corner or on the back of each illustration.

Reviewing Policy

Manuscripts submitted to *The Canadian Field-Naturalist* are normally sent for evaluation to an Associate Editor (who reviews it or asks another qualified person to do so), and at least one other reviewer, who is a specialist in the field, chosen by the Editor. Authors are encouraged to suggest names of suitable referees. Reviewers are asked to give a general appraisal of the manuscript followed by specific comments and constructive recommendations. Almost all manuscripts accepted for publication have undergone revision—sometimes extensive revision and reappraisal. **The Editor makes the final decision** on whether a manuscript is acceptable for publication, and in so doing aims to maintain the scientific quality, content, overall high standards and consistency of style, of the joumal.

Special Charges — Please take note

Authors **must share in the cost of publication** by paying $90 for each page, plus $30 for each illustration (any size up to a full page), and up to $90 per page for tables (depending on size). Authors may also be charged for their changes in proofs. Reproduction of color photos is extremely expensive; price quotations may be obtained from the Editor.

Limited joumal funds are available to help offset publication charges to authors without grants or institutional support. Requests for financial assistance should be made to the Editor when the manuscript is submitted.

Reprints

An order form for the purchase of reprints or pdf will accompany the galley proofs sent to the authors. Invoices for publication costs will be sent when the submission is published.

Subscriptions and Membership
Subscription rates for individuals are $33 per calendar year. Libraries and other institutions may subscribe at the rate of $50 per year (volume). The Ottawa Field-Naturalists' Club annual membership fee of $33 (individual) $35 (family) $50 (sustaining) and $500 (life) includes a subscription to *The Canadian Field-Naturalist*. All foreign subscribers and members (including USA) must add an additional $5.00 to cover postage. The club regional journal, *Trail & Landscape*, covers the Ottawa District and Local Club events. It is mailed to Ottawa area members, and available to those outside Ottawa on request. It is available to Libraries at $33 per year. Subscriptions, applications for membership, notices of changes of address, and undeliverable copies should be mailed to: The Ottawa Field-Naturalists Club, P.O. Box 35069, Westgate P.O. Ottawa, Canada K1Z 1A2. Canada Post Publications Mail Agreement number 40012317. Return Postage Guaranteed. Date of this issue: January–March 2007 (December 2007).

COVER: "When Blackfeet and Sioux Meet" 1908 oil painting by Charles M. Russell (1864–1926). Courtesy of Sid Richardson Museum where the original is housed. Born in St. Louis, Missouri, Charles M. Russell went west to Montana as a boy of 16 with a dream of becoming a real cowboy. Beginning in 1882, Charlie worked on various cattle drives wrangling horses where he quickly established a reputation as a likeable cowboy who loved to draw and paint. During his 11 years on the range, he witnessed the changing of the West as the days of free grass and unfenced range were ending. Charlie quit the cowboy way of life in 1893 and married Nancy Cooper three years later. With Nancy's keen business sense and belief in her husband's talent, Russell's paintings began to be known nationally. Charlie Russell felt deeply the passing of the West, the most evident theme of his art. The old ways of Indian and cowboy life had disappeared. His works reflected the public's demand for authentic pictures of the West, yet the soul of his art was romance. Were Native People Keystone Predators? A Continuous-Time Analysis of Wildlife Observations Made by Lewis and Clark in 1804-1806

Charles E. Kay

Department of Political Science, Utah State University, Logan, Utah 84322-0725 USA

Kay, Charles E. 2007. Were native people keystone predators? A continuous-time analysis of wildlife observations made by Lewis and Clark in 1804-1806. Canadian Field-Naturalist 121(1): 1–16.

It has long been claimed that native people were conservationists who had little or no impact on wildlife populations. More recently, though, it has been suggested that native people were keystone predators, who lacked any effective conservation strategies and instead routinely overexploited large mammal populations. To test these hypotheses, I performed a continuous-time analysis of wildlife observations made by Lewis and Clark because their journals are often cited as an example of how western North America teemed with wildlife before that area was despoiled by advancing European civilization. This included Bison, Elk, Mule Deer, Whitetailed Deer, Blacktailed Deer, Moose, Pronghorn Antelope, Bighorn Sheep, Grizzly Bears, Black Bears, and Grey Wolves. I also recorded all occasions on which Lewis and Clark met native peoples. Those data show a strong inverse relationship between native people and wildlife. The only places Lewis and Clark reported an abundance of game were in aboriginal buffer zones between tribes at war, but even there, wildlife populations were predator, not food-limited. Bison, Grizzly Bears, Bighorn Sheep, Mule Deer, and Grey Wolves were seldom seen except in aboriginal buffer zones. Moose were most susceptible to aboriginal hunting followed by Bison and then Elk, while Whitetailed Deer had a more effective escape strategy. If it had not been for aboriginal buffer zones, Lewis and Clark would have found little wildlife anywhere in the West. Moreover, prior to the 1780 smallpox and other earlier epidemics that decimated native populations in advance of European contact, there were more aboriginal people and even less wildlife. The patterns observed by Lewis and Clark are consistent with optimal foraging theory and other evolutionary ecology predictions.

Key Words: Native hunting, aboriginal buffer zones, Lewis and Clark, keystone predation, reference conditions, Elk, Bison, Grizzly Bears, Mule Deer, Whitetailed Deer, western North America.

It has long been postulated that native people were conservationists who had little or no impact on wildlife populations (e.g.; Speck 1913, 1939a, 1939b). Studies of modern hunter-gatherers, however, have found little evidence that native people purposefully employ conservation strategies (Alvard 1993, 1994, 1995, 1998a, 1998b; Hill and Hurtado 1996), while archaeological data suggest that prehistoric people routinely overexploited large-mammal populations (Broughton 1994a, 1994b, 1997; Jones and Hilderbrant 1995; Janetski 1997; Butler 2000; Chatters 2004). Elsewhere, I have proposed that native people were keystone predators, who once structured entire ecosystems (Kay 1994, 1995, 1997a, 1997b, 1998, 2002).

To test these competing hypotheses, I performed a continuous-time analysis of wildlife observations made by Lewis and Clark on their expedition across North America in 1804-1806 because their journals are often cited as an example of how the West teemed with wildlife before that area was despoiled by advancing European civilization (Botkin 1995, 2004; Patten 1998: 70; Wilkinson and Rauber 2002; Nie 2003: 1). Lewis and Clark were the first Europeans to traverse what eventually became the western United States, and many of the native peoples they met had never before encountered Europeans. In addition, historians universally agree that Lewis and Clark's journals are not only among the earliest, but also the most detailed and accurate, especially regarding natural history observations (Burroughs 1961; Ronda 1984; Botkin 1995, 2004). Thus, the descriptions left by Lewis and Clark are thought by many to represent the "pristine" state of western ecosystems (Craighead 1998: 597; Patten 1998: 70; Wilkinson and Rauber 2002; Botkin 2004). Botkin (1995: 1), for instance, described Lewis and Clark's journey as "the greatest wilderness trip ever recorded."

Methods and Study Area

Recently, Martin and Szuter (1999a, 1999b, 2002, 2004), Lyman and Wolverton (2002), and Laliberte and Ripple (2003) presented contrasting interpretations of western ecosystems based on Lewis and Clark's journals, but those analyses are flawed, in part, because they either did not separate ungulates by species or they did

not correlate wildlife sightings with the abundance of native people on each day of the entire trip. Instead, I developed three measures to quantify the wildlife observations recorded by Lewis and Clark in their original journals, which have recently been re-edited and republished (Moulton 1986, 1987a, 1987b, 1988, 1990, 1991, 1993 – hereafter cited only by volume and page). First, game seen. If Lewis and Clark reported old sign of a species, that was assigned a value of one, fresh sign a two, and if they actually saw the animal, a three. This included Bison (*Bison bison*), Elk (*Cervus elaphus*), Whitetailed Deer (*Odocoileus virginianus*), Mule Deer (*O. hemionus hemionus*), Blacktailed Deer (*O. h. columbianus*), Moose (*Alces alces*), Pronghorn Antelope (*Antilocapra americana*), Bighorn Sheep (*Ovis canadensis*), Grizzly Bears (*Ursus arctos*), Black Bears (*U. americanus*), and Grey Wolves (*Canis lupus*). This was done each day for the entire 863 days of the expedition.

Second, game killed. On each day, Lewis and Clark recorded the exact number of animals that were killed to provision their party. In three instances, though, Lewis and Clark reported that "some" Whitetailed Deer (day 78), Elk (day 365), or Bison (day 413) were killed. In these cases, "some" was recorded as three animals killed. In 12 instances, Lewis and Clark reported that "several" Whitetailed Deer (days 46, 365, 367, 373, 408, and 811), Bison (days 354, 406, 408, and 413), Mule Deer (day 404), or Blacktailed Deer (day 602) were killed. In those cases, "several" was recorded as seven animals killed. Similar to game seen, the number of animals killed was recorded for all species on all days.

Third, herd size. If Lewis and Clark reported sighting large numbers of a particular animal, a value of ten was assigned to that species on that day. A value of ten was also assigned if Lewis and Clark reported killing 10 or more of one species on a single day. I then added game seen, game killed, and herd size values for all species on each day to obtain a daily measure of wildlife abundance. Again, this was done for all 863 days of the expedition.

I also developed a similar convention to quantify the relative abundance of native people that Lewis and Clark encountered each day of their journey. If Lewis and Clark observed old sign, that was assigned a value of one, fresh sign a two, and if Lewis and Clark actually saw native people, a three. If Lewis and Clark met more than ten native people on a given day that was assigned a value of ten. On most days Lewis and Clark traveled together but on a few occasions they took separate routes, most notably on the return trip. In those cases, Lewis' observations were recorded separately from Clark's. These conventions produced nearly 40 000 numerical data entries. To facilitate analysis, Lewis and Clark's route was divided into 55 trip segments (Table 1), for which mean daily abundances of wildlife and mean daily abundances of native people were calculated. It should be noted that Lewis and Clark generally sent their best hunters ahead of the main party so that game would more readily be encountered.

Lewis and Clark left St. Louis, Missouri on 14 May 1804 and proceeded, via watercraft, up the Missouri River through present-day Missouri, Kansas, Nebraska, Iowa, South Dakota, and into North Dakota where they built Fort Mandan in close proximity to the Mandan and Hidatsa villages. Lewis and Clark over-wintered at Fort Mandan, and then ascended the Missouri River into present-day Montana during the spring of 1805. After leaving their larger boats and portaging the Great Falls, Lewis and Clark continued up the Missouri to Three Forks before ascending the Jefferson and Beaverhead Rivers, on whose upper reaches they met the Shoshone. After obtaining horses from the Shoshone, Lewis and Clark cached their canoes where Clark Canyon Reservoir is now situated and traveled over the Continental Divide into Idaho and down the Lemhi and Salmon Rivers. From there, Lewis and Clark ascended the North Fork of the Salmon and crossed Lost Trail Pass, re-entering Montana.

Next, Lewis and Clark traveled down the Bitterroot Valley to Lolo Creek, which they traced to its source. Lewis and Clark then followed the high ridges north of Idaho's Lochsa River and eventually descended to the lower Lochsa, where the explorers met the Nez Perce. At this point, Lewis and Clark left their horses and proceeded via canoe down the Clearwater, Snake, and Columbia Rivers through present-day Oregon and Washington state. Finally, Lewis and Clark built Fort Clatsop and overwintered on the south bank of the Columbia near the Pacific Ocean.

During the spring of 1806, Lewis and Clark retraced their route, with minor variations, until the expedition reached present-day Lolo, Montana, where the party divided. Lewis ascended the Blackfoot River, crossed the Continental Divide, and proceeded to the Great Falls on the Missouri River, where the party split a second time. Lewis left most of his men to repair the boats cached in 1805, while he and three companions traveled by horseback to Cutbank Creek, where they met the Blackfeet. After the only fatal encounter with native people on the entire trip, Lewis retreated to the Missouri, where he rejoined the rest of his men and together they floated down that river until reunited with Clark below the Yellowstone in present-day North Dakota.

Clark, on the other hand, left Lolo, Montana, and ascended the Bitterroot River to Chief Joseph Pass, where he entered the Big Hole. From there, Clark crossed to the Beaverhead and refloated the canoes cached in 1805. Clark's party then proceeded by land and water to Three Forks, where the group split a second time. Clark sent some of his men and the canoes down the Missouri to meet Lewis at Great Falls, while he traveled overland via Bozeman Pass to the Yellowstone. At this point, Clark fashioned canoes and floated down the Yellowstone and Missouri Rivers until reunited with

TABLE 1. Trip segments and itinerary of Lewis and Clark 1804-1806.

Trip segment	Segment length (days)	Description	Dates
1	30	St. Louis to Grand River, Missouri	5/14-6/12/1804
2	50	Grand River to Council Bluffs, Nebraska	6/13-8/1/1804
3	20	Council Bluffs to Big Sioux River, Nebraska	8/2-8/21/1804
4	4	Big Sioux River to above Vermillion River, Nebraska	8/22-8/25/1804
5	8	Above Vermillion River	8/26-9/2/1804
6	22	Above Vermillion River to Bad River, South Dakota	9/3-9/24/1804
7	22	Bad River to below the Cannonball River, North Dakota	9/25-10/16/1804
8	7	Cannonball River to Mandan Villages, North Dakota	10/17-10/23/1804
9	9	Mandan Villages, North Dakota	10/24-11/1/1804
10	156	Fort Mandan, North Dakota	11/2/1804-4/6/1805
11	6	Fort Mandan to Little Missouri River, North Dakota	4/7-4/12/1805
12	13	Little Missouri River to Yellowstone River, North Dakota	4/13-4/25/1805
13	12	Yellowstone River to Milk River, Montana	4/26-5/7/1805
14	12	Milk River to Musselshell River, Montana	5/8-5//19/1805
15	14	Musselshell River to Marias River, Montana	5/20-6/2/1805
16	13	Marias River to Great Falls, Montana	6/3-6/15/1805
17	29	Great Falls portage	6/16-7/14/1805
18	10	Great Falls to Three Forks, Montana	7/15-7/24/1805
19	13	Three Forks to Big Hole River, Montana	7/25-8/6/1805
20	6	Big Hole River to meeting Shoshone in Idaho – Lewis' account	8/7-8/12/1805
21	14	Present Clark Canyon Reservoir across divide to Lemhi River, Idaho – Lewis' account	8/13-8/26/1805
22	16	Above Three Forks to present Clark Canyon Reservoir, Montana – Clark's account	8/1-8/16/1805
23	12	Clark Canyon Reservoir to Lemhi River to Salmon River and return to Lemhi – Clark's account	8/17-8/28/1805
24	13	Lemhi River, Idaho, to present Lolo, Montana	8/29-9/10/1805
25	9	Lolo, Montana, over Lolo Trail to lower Lochsa River, Idaho	9/11-9/19/1805
26	17	Lower Lochsa River – canoe camp	9/20-10/6/1805
27	18	Canoe Camp to the Dalles, Washington	10/7-10/24/1805
28	9	Cascade Mountains and portage, Washington	10/25-11/2/1805
29	22	Cascade Mountains to the mouth of Columbia River on the north bank, Washington	11/3-11/25/1805
30	11	Crossed to south bank of the Columbia River, Oregon	11/26-12/6/1805
31	106	Ft. Clatsop, Oregon	12/7-3/22/1806
32	15	Ft. Clatsop to the Cascade Mountains, Washington	3/23-4/6/1806
33	12	Cascade Mountains to the Dalles, Washington	4/7-4/18/1806
34	25	The Dalles to Camp Chopunnish, Idaho	4/19-5/13/1806
35	27	Camp Chopunnish, Idaho	5/14-6/9/1806
36	15	Attempted crossing of mountains	6/10-6/24/1806
37	5	Crossed mountains on Lolo Trail	6/25-6/29/1806
38	3	Present Lolo, Montana – here Lewis and Clark separated	6/30-7/2/1806
39	5	Lewis – up Blackfoot River and across Continental Divide, Montana	7/3-7/7/1806
40	14	Lewis – Divide to Great Falls (split party) Lewis to Cutbank Creek, Montana	7/8-7/21/1806
41	6	Lewis – Upper Cutbank Creek, met Piegan, fled back to Missouri River	7/22-7/27/1806
42	11	Lewis – Marias River down Missouri to Yellowstone River, North Dakota	7/28-8/7/1806
43	4	Lewis – Down Missouri until reunited with Clark	8/8-8/11/1806
44	10	Clark – Lolo, Montana, up Bitterroot into Big Hole Valley then to present Clark Canyon Reservoir and down to Three Forks where the party again split	7/3-7/12/1806
45	3	Clark – Three Forks to Bozeman Pass and on to the Yellowstone River, Montana	7/13-7/15/1806
46	18	Clark – Down Yellowstone River to Missouri River, North Dakota	7/16-8/2/1806
47	9	Clark – Down Missouri River until reunited with Lewis, North Dakota	8/3-8/11/1806
48	6	Little Missouri River to Mandan Villages to Ft. Mandan, North Dakota	8/12-8/17/1806
49	3	Heart River to Cannonball River, North Dakota	8/18-8/20/1806
50	2	Aricara villages, South Dakota	8/21-8/22/1806
51	7	Moreau River to White River, South Dakota	8/23-8/29/1806
52	5	White River to Vermillion River, Nebraska	8/30-9/3/1806
53	5	Big Sioux River to Council Bluffs, Nebraska	9/4-9/8/1806
54	9	Platte River to Grand River, Missouri	9/9-9/17/1806
55	6	Grand River to St. Louis, Missouri	9/18-9/23/1806

Lewis. Lewis and Clark then descended to St. Louis (2: 64; 3: 6; 4: 6; 5: 6, 110, 176; 6: 6, 80; 7: 6; 8: 8-9, 49, 84).

Results

Lewis and Clark's observations show an inverse relationship between wildlife and native people (Figure 1). Wildlife was abundant only where native people were absent, and if it had not been for the presence of aboriginal buffer zones between tribes at war (Hickerson 1965; Steffian 1991; Martin and Szuter 1999a, 1999b, 2002, 2004; Farr 2001; Laliberte and Ripple 2003), there would have been little wildlife anywhere in the West.

Yankton Sioux buffer zone

As Lewis and Clark ascended the Missouri River, they met the Omahas and Ottes on day 97 and the Yankton Sioux on day 108 (Figure 2). These two groups were at war (2: 488), and wildlife was abundant only in the buffer zone between the tribes. Bison, in particular, were found only in the center of the buffer zone.

Sioux-Mandan buffer zone

Lewis and Clark met the Teton Sioux on day 135, the Arikaras on day 148, and the Mandan-Hidatsa on day 164. Wildlife was not abundant in the area between the Teton Sioux and the Arikaras, but was abundant between the Arikaras and the Mandan-Hidatsa (Figure 3). This was because the Teton Sioux and Arikaras were allied against the Mandan-Hidatsa (3: 156, 161, 195-196, 207, 226, 233-234, 243-244, 251, 272-273, 295-297, 304-305; Porsche and Loendorf 1987; Bouchet-Bert 1999). That is, peace had a negative impact on wildlife populations while war had a beneficial effect, similar to conditions Hickerson (1965) reported in the upper Mississippi Valley (Farr 2001).

Missouri-Yellowstone buffer zone

In 1804-1806 all of Montana between the Missouri and Yellowstone Rivers was a six-sided buffer zone between warring tribes (4: 21-22, 67, 108-109, 159-160, 216, 222, 354, 379, 401, 426, 437; 5: 8-9, 45, 68-71, 77-80, 85, 87-91, 96-97, 102-106, 123-124, 178, 197, 259, 318; 7: 242, 250; 8: 88, 93-94, 104, 113, 123, 143, 182, 195, 278, 321, 323). The north was controlled by the Blackfeet Confederation, which consisted of five tribes (Ewers 1958), while on the west were the Flathead, Salish, Kootenay, and their allies. The Shoshone occupied the southwest (Trenholm and Carley 1964), the Crow the south-central, and the Sioux, Cheyenne, and their allies the southeast. To the east were the Mandan, Hidatsa, and their allies (Ahler et al. 1991). Within this large buffer zone (Martin and Szuter 1999a, 2002, 2004; Farr 2001), wildlife was relatively more abundant (Figures 4-7) because the warring factions did not hunt along the Yellowstone and Missouri as frequently as they did more secure environments closer to each tribe's core area. As noted by Lewis and Clark, tribes did venture into the buffer zone,

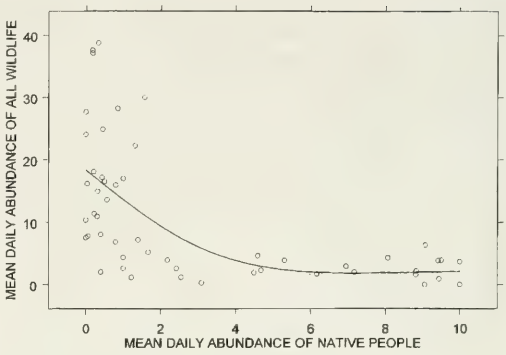

FIGURE 1. Relationship between the abundance of native people and the abundance of wildlife as observed by Lewis and Clark in 1804-1806. Plotted are the mean daily abundance of all wildlife species and the mean daily abundance of native people by trip segments – segments 1, 2, 54, and 55 were excluded because those areas were near European settlements. Line fitted using a smoothing spline with cross validation (Mathsoft 1997: 158-167). X and Y axes are offset. Note that there are no data points in the upper right as might be expected if cultural beliefs fostered conservation. Clearly, it made little difference what native people believed, or said they believed. Instead, aboriginal hunting followed predictions derived from optimal foraging theory and other evolutionary ecology models.

but only in force due to fear of attack. So the Missouri-Yellowstone buffer zone was not unhunted (4: 232), instead the area was just hunted less frequently (Farr 2001), which apparently was sufficient to permit greater numbers of wildlife.

Deer

Lewis and Clark killed more Whitetailed Deer than all other large mammals combined. By comparison, Mule Deer were rare and were found only in tribal boundary zones, while blacktails were restricted to the Cascade Mountains west to the Pacific (6: 328, 331, 403-404). Even along the lower Columbia, though, Lewis and Clark encountered more whitetails than blacktails. This was because whitetails had a more effective escape strategy than the other deer (Geist 1998; Whittaker and Lindzey 2001; Lingle 2002; Robinson et al. 2002) and thus were less affected by native hunting. Even where native people were abundant, some whitetails were usually able to survive (Figure 8a) because, when discovered, whitetails quickly fled into riparian thickets from which they could not easily be dislodged (5: 87; 6: 403). Lewis and Clark noted that Mule Deer and Elk when chased fled into the open (4: 136-137; 6: 403), making those species easier to hunt.

Elk

Lewis and Clark reported that Elk were easier to kill than Whitetailed Deer (6: 85, 242), which is reflected in the fact that native hunters had a greater impact on

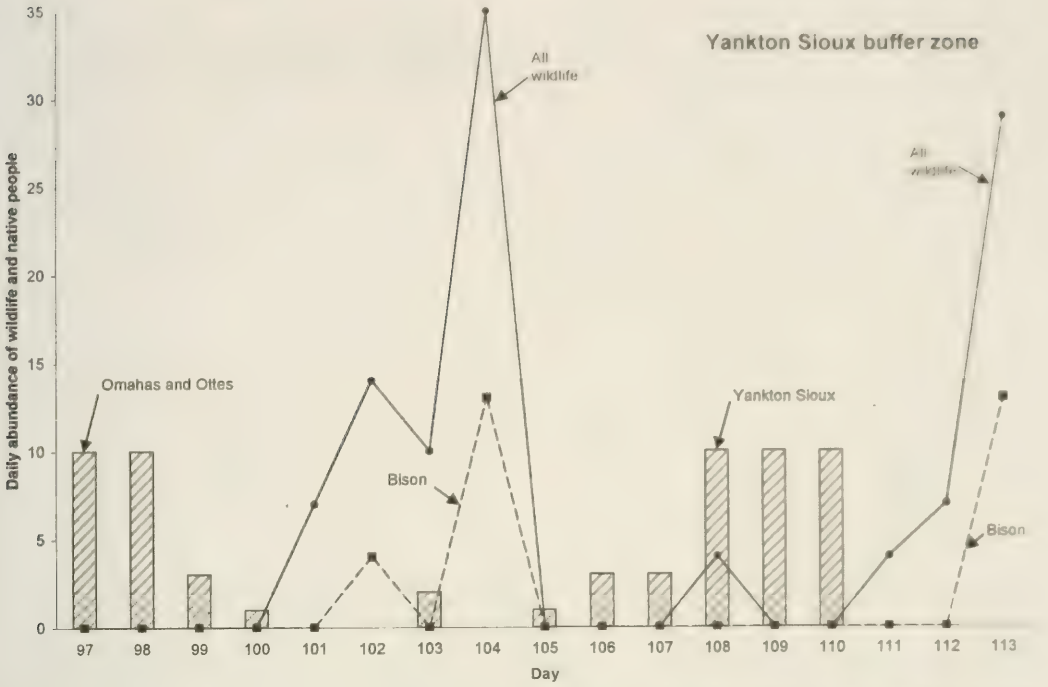

FIGURE 2. Yankton Sioux buffer zone along the Missouri River as reported by Lewis and Clark in 1804. Wildlife was abundant only in the zone between warring tribes.

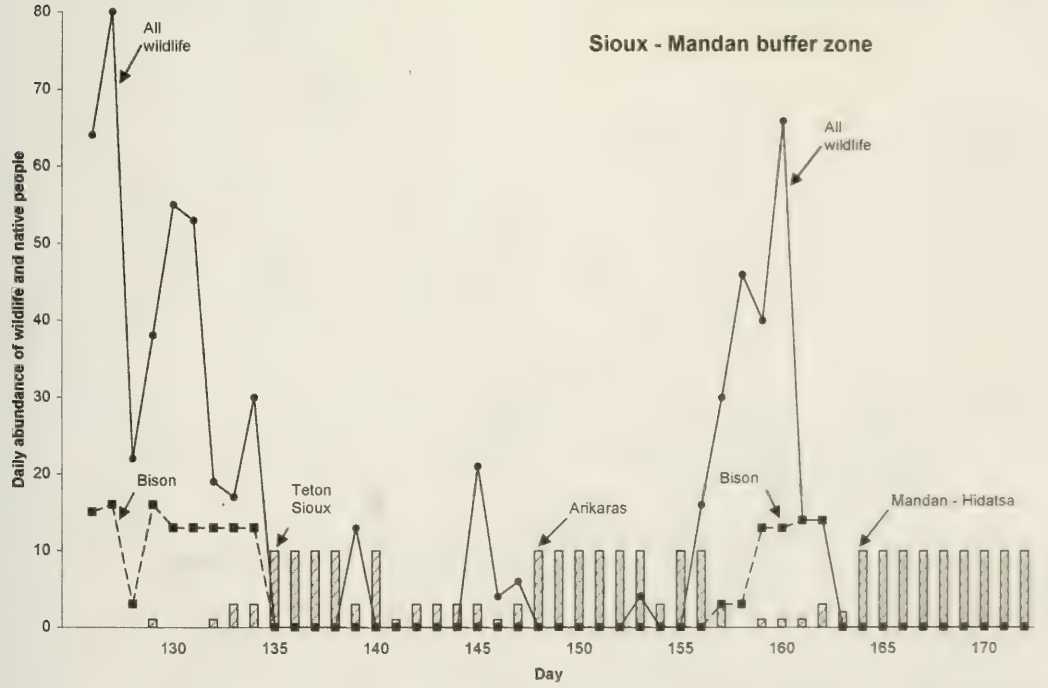

FIGURE 3. Sioux-Mandan buffer zone along the Missouri River as reported by Lewis and Clark in 1804. The Teton Sioux were allied with the Arikaras against the Mandan-Hidatsa and wildlife was abundant only in the zone between warring factions. There was little wildlife and no Bison in the area between the allied tribes.

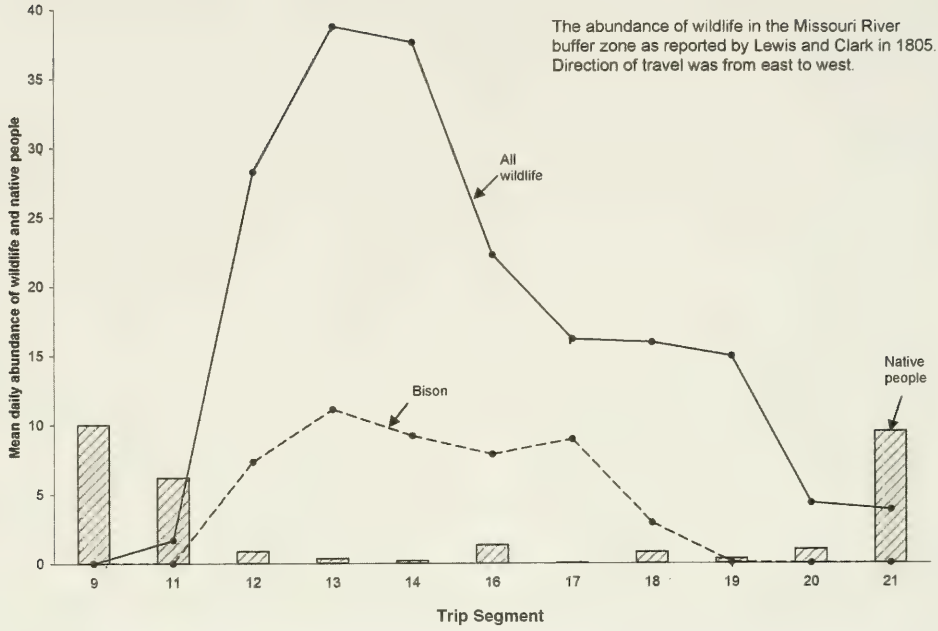

FIGURE 4. The mean daily abundance of wildlife and native people along the Missouri River buffer zone as reported by Lewis and Clark in 1805. On their trip across this section of Montana, Lewis and Clark did not see a single native person from the time they left the Mandan (trip segments 9 and 11) until they met the Shoshone along the Montana-Idaho border (trip segment 21). Bison were observed only where native people were absent.

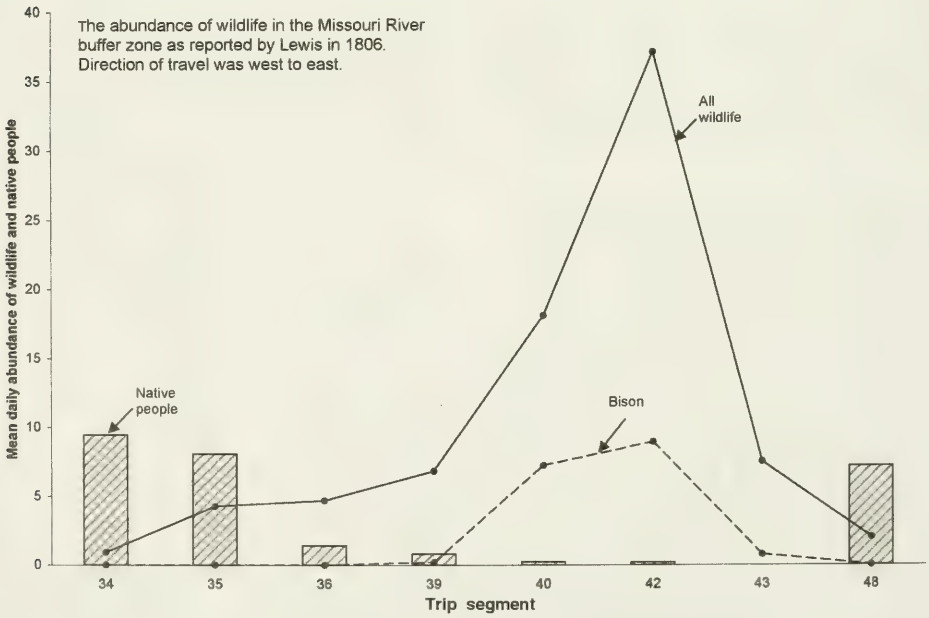

FIGURE 5. The mean daily abundance of wildlife and native people along the Missouri River buffer zone as reported by Lewis in 1806. Trip segment 34 included tribes in central Washington, while Lewis and Clark spent trip segment 35 with the Nez Perce. Lewis and Clark then crossed the Bitterroot Mountains (trip segment 36) and separated at Lolo, Montana. By trip segment 40, Clark was back at Great Falls on the Missouri River, which he descended to the Mandan villages (trip segment 48). As on the upstream journey (Figure 4), Clark did not see a single native person on this section of the Missouri and wildlife was abundant only where native people were absent. Bison, in particular, occurred only in the center of the buffer zone.

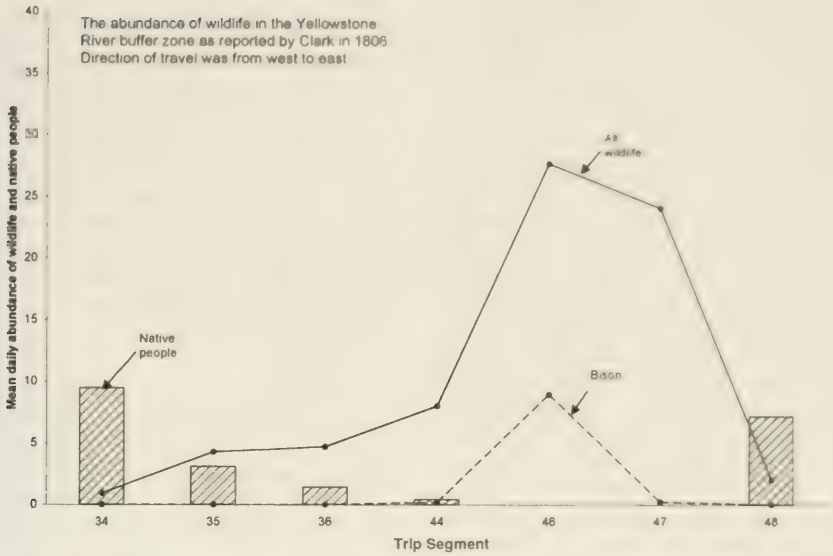

FIGURE 6. The mean daily abundance of wildlife and native people along the Yellowstone River buffer zone as reported by Clark in 1806. Trip segments 34, 35, and 36 are the same as those in Figure 5. After Lewis and Clark separated, Clark returned to Three Forks by trip segment 44 and was on the Yellowstone River by trip segment 46. Although the Crow stole all of Clark's horses on the Yellowstone, he did not actually see a single native person on his return trip across Montana until he neared the Mandan villages (trip segment 48). The only place wildlife was abundant was along the Yellowstone River and Bison were only seen in the center of that buffer zone.

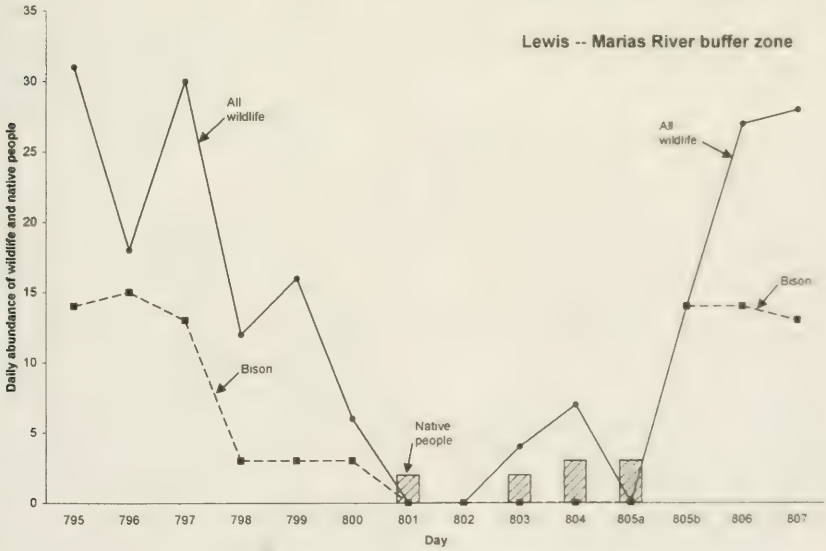

FIGURE 7. Marias River buffer zone. After returning to Great Falls, Lewis ascended the Marias River and Cutbank Creek in what is now the Blackfeet Indian Reservation. As Lewis traveled from the Missouri, wildlife became less and less abundant, while Bison disappeared. Wildlife was reported on days 803 and 804 only because Lewis sent his hunters downstream 30-40 km to kill Whitetailed Deer for food. On day 804 Lewis met seven Blackfeet who told him their village was less than one-half day's travel. Lewis camped with this small group of Blackfeet and next morning (day 805a) awoke to find the Blackfeet attempting to steal his guns and horses. An altercation followed and at least one Blackfoot was killed, the only native person killed by Lewis and Clark on their entire journey. Fearing retaliation and annihilation, Lewis fled back to the Missouri, and by his own account, traveled more than 160 km by nightfall (day 805b). Thus within one day's hard travel, Lewis went from an area with no game and native people to an area with abundant game and no natives. Bison were found only where native people were absent (8: 112-140).

the abundance of Elk (Figure 8b) than they did deer (Figure 8a). Lewis and Clark did kill a number of Elk at Fort Clatsop, but only because they purposefully built the fort where Elk were relatively more common and native people infrequent (6: 92-93, 95-96, 105, 108, 112). That is, Lewis and Clark constructed Fort Clatsop in an intervillage buffer zone to take advantage of the more abundant Elk. Nevertheless, Lewis and Clark observed that most of the Elk they killed during the winter of 1805-1806 had old arrow wounds (6: 208, 210), indicative of intense native hunting. "Many of the Elk we have killed since we have been here, have been wounded with these arrows, the short piece with the barb remaining in the animal and grown up in the flesh" (6: 208). Lewis and Clark also described how native people used pit traps to kill Elk. "Then pits are employed in taking the Elk, and of course are large and deep, some of them a cube of 12 or 14 feet. These are usually placed by the side of a large fallen tree, which as well as the pit [lie] across the [trails] frequented by the Elk. [The] pits are disguised with the slender boughs of trees and moss; the unwary Elk in passing the tree precipitates himself into the pit which is sufficiently deep to prevent his escape" (6: 208). Thus, even in thick coastal forests, Elk were intensely hunted by native people.

Pronghorn Antelope

Native hunting had an even greater impact on the abundance of Pronghorn Antelope (Figure 8c). Despite their great speed, pronghorns were relatively easy for native people to kill (3: 176; Frison 1991).

Bison

Native hunting controlled the distribution and number of Bison on the northern Great Plains (Figure 8d). The only places Lewis and Clark saw Bison, and especially in large numbers, were in the center of aboriginal buffer zones between warring tribes. This is similar to what West (1995) documented on the central Great Plains – if it had not been for warring tribes and buffer zones, there would have been few Bison anywhere in North America (Kay 2002).

Bighorn Sheep

Native hunting had an even greater effect on Bighorn Sheep (Figure 8e). Lewis and Clark reported an abundance of bighorns only in the center of buffer zones far removed from native people.

Grizzly Bears

Native hunters also controlled the distribution and abundance of Grizzly Bears (Figure 8f). This is similar to what Birkedal (1993) reported in Alaska. Aside from a few grizzlies killed in the rugged Idaho mountains, Lewis and Clark only observed grizzlies in aboriginal buffer zones.

Black Bears

Based on Lewis and Clark's observations and kill rates, Black Bears were less common than grizzlies, even in forested areas.

Moose

Despite spending substantial amounts of time in what is currently prime Moose habitat, Lewis and Clark recorded Moose only once (6: 313; 7: 326; 8: 95) and that was in the center of the buffer zone between the Blackfeet and the Flathead-Salish. As explained elsewhere, native hunting controlled the distribution and abundance of Moose throughout western North America (Kay 1997b). Contrary to what is generally believed, Moose are more abundant in western North America today (Stevens 1971; Pierce and Peek 1984) than they were in Lewis and Clark's time, or any other point in the past (Kay 1997b).

Grey Wolves

Lewis and Clark observed a direct relationship between the abundance of game and the abundance of wolves. Wolves were common only where game was relatively abundant (4: 85). Thus, wolves were largely restricted to the same aboriginal buffer zones as were Bison, Elk, and other ungulates.

Dogs and horses

I also recorded the number of dogs (*Canis familaris*) Lewis and Clark purchased when game was in short supply, and the number of horses (*Equus caballus*) the explorers killed for food. Lewis and Clark killed nine horses and bought (ate) 210 dogs, primarily in the Columbia Basin, where native people were particularly abundant and wildlife was virtually non-existent (7: 49, 92). Lewis and Clark also bought large quantities of other foodstuffs from various native peoples, especially corn from the Mandan-Hidatsa and salmon from tribes throughout the Columbia Basin.

Discussion

Optimal-foraging theory

According to optimal-foraging theory, high-ranked diet items are more susceptible to overexploitation than lower-ranked items (Smith 1983; Stephens and Krebs 1986; Smith and Winterhalder 1992; Butler 2000). Theoretical considerations and studies of modern hunter-gatherers both indicate that large mammals are the highest-ranked diet items, and that, in general, the larger the animal, the higher its rank (Smith and Winterhalder 1992; Hill and Hurtado 1996). Moreover, if risk to the hunter or travel distances are great, only the highest-ranked diet items should be pursued (Smith and Winterhalder 1992). Thus, optimal-foraging theory would predict that when native people entered aboriginal buffer zones, they should have concentrated their hunting on the larger species, such as Bison and Elk, causing those species to decline accordingly. This would also imply that native people lacked any effective conservation strategy regarding these prey items. This pattern was, in fact, observed by Lewis and Clark as they left various native peoples and entered buffer zones, first Whitetailed Deer increased, then Elk and then Bison. Conversely, as Lewis and Clark exited a buffer zone, Bison disappeared first, followed by Elk, while

FIGURE 8. Relationship between the abundance of native people and the abundance of various wildlife species as observed by Lewis and Clark in 1804-1806. Plotted are the mean daily abundance of species and the mean daily abundance of native people by trip segments – segments 1, 2, 54, and 55 were excluded because those areas were near European settlements. Lines fitted using a smoothing spline with cross validation (Mathsoft 1997: 158-167). X and Y axes are offset. (a) Whitetailed Deer, (b) Elk, (c) Pronghorn Antelope, (d) Bison, (e) Bighorn Sheep, and (f) Grizzly Bears.

some Whitetailed Deer were usually able to escape native hunters (Figure 9). Furthermore, Lewis and Clark noted that native hunters preferred to kill female ungulates (3: 61, 270) due to that sex's higher fat content. Now, killing females runs counter to any conservation strategy (Kay 1994, 1997b, 1998; Kay and Simmons 2002).

Alvard (1998b, 2002) recently reviewed the conditions under which evolution by natural selection might favor resource conservation by humans. In short, conservation will be favored by evolution only if the resource is economical to defend. For instance, if 1000 kcal are spent defending a resource, but less than 1000 kcal are derived from that resource, evolution will not favor conservation. For a variety of reasons, including competition from carnivore predators, large mammals were seldom, if ever, economical to defend (Kay 1994, 1998, 2002). Instead the logical, rational thing to do was to kill-out the large mammals as quickly as possible and then move on to other resources,

which is exactly what aboriginal people did (Kay 1998, 2002). Counter-intuitively, once that was accomplished, native populations actually increased because people were forced to consume lower-ranked, but more abundant diet items (Hawkes 1991, 1992, 1993). There is also an evolved discount rate that acts to negate a wide range of possible conservation practices (Rogers 1991, 1994).

Predator-limited

Even within buffer zones, though, wildlife was not as abundant as one might think, because the animals were predator, not food, limited (Kay 1998, 2002). Food-limited ungulates invariably destroy berry-producing shrubs and woody riparian vegetation due to repeated browsing, and once willows (*Salix* spp.), cottonwoods (*Populus* spp.), and aspen (*Populus tremuloides*) decline, so do associated species like Beaver (*Castor canadensis)* (4: 189-190), which are dependent upon those plants for food (Kay 1998 and references therein; Nietvelt 2001). Lewis and Clark, however, reported that riparian thickets were common in buffer zones, as were Beaver and berry-producing shrubs (e.g.; 4: 70, 145-146, 189-190, 247, 278, 332, 374, 391-392, 399, 414, 419, 428, 435, 451; 5: 14, 42, 46, 59). In addition, Lewis and Clark noted that Whitetailed Deer often had twin fawns or triplets, and that even lactating deer were fat (4: 165), which would not have been physiologically possible if ungulate populations had been food-limited. Thus, carnivore predation and occasional hunting by native people (4: 232) kept buffer zone ungulate populations well below what the habitat could otherwise support (White et al. 1998; Kay 2002).

Estimate of pre-Columbian wildlife populations

A number of investigators have cited Lewis and Clark's descriptions of abundant wildlife without realizing that those accounts only apply to the center of buffer zones (Craighead 1998; Wilkinson and Rauber 2002). Botkin (1995: 49-86; 2004: 141-147), for instance, used Lewis and Clark's observations of grizzlies along the Missouri and Yellowstone Rivers to estimate the number of bears in the western United States prior to European contact, and arrived at a figure of 56 000, which others increased to 100 000 for the entire continent (e.g.; Flores 1998: 61). Although Botkin (1995: 165-169) acknowledged that native people could be important ecological factors, he failed to realize that native hunting controlled the distribution and numbers of grizzlies throughout North America (Figure 8f; Birkedal 1993). During pre-Columbian times, there may have been no more than 4000-5000 grizzlies in all of North America because the bears were simply large packages of fat meat that native hunters killed at will (Hallowell 1926: 31-37; Birkedal 1993). Similarly, there never were 60 million Bison on the Great Plains (Seton 1929; Roe 1951), as is commonly believed (Shaw 1995; Geist 1996; Kay 2002).

Canadian buffer zones

Aboriginal buffer zones also occurred throughout western Canada. Palliser, for instance, reported that "As a general rule the more dangerous the country [due to Indian attack] the greater the probability of finding [an] abundance of game, showing in more ways than one the truth of the old sportsman's adage the more danger the more sport. This part of the country is so evidently the line of direction [demarcation] between the three hostile tribes, that none of them dare venture into it for hunting, except when driven to desperation by hunger, they endeavor to snatch their game from between the jaws of Scylla and Charybdis. Much therefore as I enjoyed [this] locality for a hunting camp, seeing buffalo on all sides, elk feeding in the distance, and fresh deer tracks in every direction... Boucharville [Palliser's companion] did not relish it at all, and began already to calculate how soon we were to go away" (Palliser 1969: 266-267). "The abundance of game here [and not anywhere else] is accounted for by its being the neutral ground of the Crees, Assineboines, and Blackfeet; none of these tribes are in the habit of resorting to its neighborhood except in war parties.... We are now in the heart of the buffalo country. This region may be called a buffalo preserve, being the battle-ground between the Crees and the Blackfeet..." (Spry 1968: 146). Like Lewis and Clark, Palliser observed grizzlies primarily in aboriginal buffer zones.

Alexander Henry the Younger, describing conditions on the Red River, also noted that grizzlies were found almost exclusively in aboriginal buffer zones – "they [grizzlies] are – very numerous, and seldom are molested by the hunters [Indians], it being the Frontier of the Sieux [sic] and their enemy where none can hunt in safety. Here they [the bears] breed and multiply in the greatest security" (Gough 1988: 72). While Henry Hind (1971: 28-29) reported the presence of five aboriginal buffer zones on the northern Great Plains – four in Canada and one in the United States. "The following are celebrated 'war-paths,' where hunting is generally disallowed although game from that circumstance is usually more abundant. 1. 'The War-path River' and war road of the Lac la Pluie, Ojibways and the Sioux, from Rainy River to Red Lake River, thence across the prairies in the Valley of Red Lake River to Miniwahen or Devil's Lake, in Dakotah [sic] Territory. 2. 'War-path River,' from the southwest corners of Lake of the Woods to Roseau River, thence to the prairies west of Red River – same tribes. 3, 'War-path River', from Lake Winnipeg to the Little Sashatchewan [sic], thence to the prairies south of Manitobah [sic] Lake – the old war-path of the Swampy Crees, the Assinaiboines and Sioux, also of the Swampy Crees and the Lake Winnipeg Ojibways. 4. The 'war-road' near the Elbow of the South Branch of the Sashatchewan [River], on the flanks of the Grand Coteau, of the Blackfeet and Plain Crees. 5. The 'war-road' of the Sioux, Blackfeet and

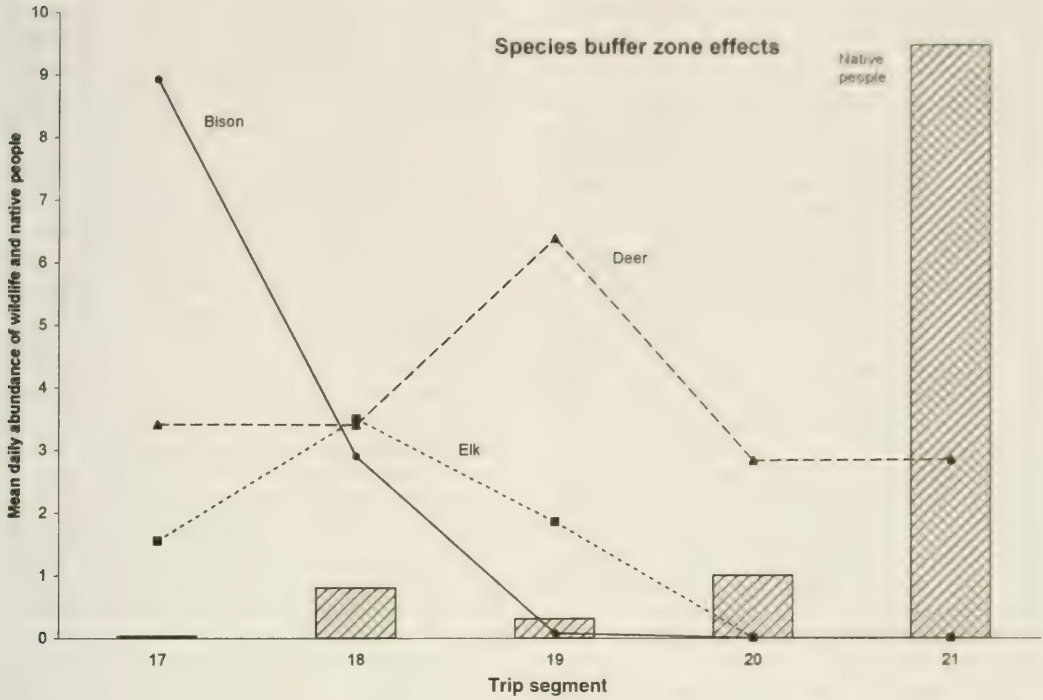

FIGURE 9. The effect of native hunting on Bison, Elk, and Whitetailed Deer. As Lewis and Clark ascended the Missouri River from Great Falls (trip segment 17) and finally met the Shoshone (trip segment 21), wildlife became less and less abundant. First, Bison disappeared, and then Elk, until only a few Whitetailed Deer remained. This is the pattern that would be expected if native hunters foraged optimally without regard to conservation.

Crows, in the Valley of the Yellowstone [River]". In addition, both Alexander Mackenzie and Samuel Black noted the presence of an aboriginal buffer zone along the lower Peace River in northern British Columbia (Rich 1955: 112; Lamb 1970: 279, 288-289, 404-407). Similarly, Alexander Mackenzie reported a major Indian-Inuit buffer zone in the far north on his 1789 trip to the Arctic Ocean (Lamb 1970: 181-233) as did Franklin (1969) in 1821-1822.

As in the United States, most observations of wildlife in western Canada recorded by early European explorers, including virtually all sightings of Grizzly Bears, occurred in aboriginal buffer zones. Heretofore these buffer zone observations have been interpreted to mean that all of western Canada once teemed with game, which is simply not true. Instead, many areas of western Canada were almost devoid of wildlife due to intense native hunting (Kay et al. 2000).

Prey behavior

Lewis and Clark also reported a direct relationship between prey behavior and native hunting. In the center of buffer zones, where native people hunted only infrequently, game was relatively tame and could easily be approached (e.g., 4: 67, 108). Elsewhere, however, game was exceedingly wary. "The country about the mouth of this river [Little Missouri] had been recently hunted by the Minetares, and the little game which they had not killed and frightened away, was so extreemly [sic] shy that ... [our] hunters could not get in shoot [range] of them" (4: 26). "The Borders of the river [Missouri] has so much hunted by those Indians ... [that] the game is scerce [sic] and veery [sic] wild" (4: 39). This also applied to Grizzly Bears and other animals. "[The bears] appear more shy here [near the Shoshone] than on the Missouri below the mountains" (4: 426). "These anamals [sic] [beaver] in consequence of not being hunted [in a buffer zone] are extreemly gentle, where they are hunted [though] they [the beaver] never leave their lodges in the day" (4: 100). Similarly, in 1819 Long observed that Bison fled in panic at the mere scent of humans. "The wind happening to blow fresh from the south, the scent of our party was borne directly [to the Bison], and we could distinctly note every step of [our scent's] progress through a distance of eight or ten miles, by the consternation and terror it excited among the buffaloes. The moment the tainted gale infected their atmosphere, [the Bison] ran with as much violence as if pursued by a party of mounted hunters" (Thwaites 1905: 255-256) – not unexpectedly, these observations were made in an aboriginal buffer zone along the Platte River in eastern Colorado (West 1995). This is identical to what Diamond (1984) reported in New Guinea, where even low-intensity aboriginal hunting completely altered the be-

havior of prey species, as well as significantly reducing prey number (Kay 2002).

Habitat

Over the years, I have retraced most of Lewis and Clark's route across North Dakota, Montana, Idaho, Washington, and Oregon, and there are no habitat features that could explain the distribution and abundances of the various species observed by the explorers. Lewis and Clark, for instance, did not find any "buffalo" in the large, treeless valleys of southwest Montana. This they attributed to the fact that Bison had been driven-out and/or killed-out by Shoshone hunters, not habitat characteristics (8: 182). At another point in their journey, Lewis and Clark commented on how they could see no difference between the country west of the mountains and the plains along the Missouri, except that wildlife was common only on the latter. "I see very little difference between the apparent face of the country here [eastern Washington and western Idaho] and that of the plains of the Missouri only that these [the Columbia Basin grasslands] are not enlivened by the vast herds of buffaloe [sic] Elk [etc] which ornament the other" (7: 196). Bighorn Sheep are certainly restricted to areas with precipitous escape terrain, but Lewis and Clark found bighorns common only in the center of aboriginal buffer zones. Other suitable habitat was unoccupied because those areas were more frequently used by native people.

Moreover, there is no evidence to support the assertion by Mack and Thompson (1982) or Lyman and Wolverton (2002) that Bison and other ungulates were rare in the Columbia Basin because those grasslands were nutritionally deficient. First as Daubenmire (1985) and others have noted, the Columbia Basin supported an open range livestock industry for nearly 40 years during the late 1800s (Oliphant 1968; Galbraith and Anderson 1971). Since cattle are less efficient herbivores than Bison, there is no physiological reason Columbia Basin grasslands could have supported large numbers of free-ranging cattle and not Bison (Van Vuren 1987; Urness 1989). In addition, a modern Elk herd on Columbia grasslands not only grew at near the maximum rate of increase for that species, but produced huge record-book antlers, as well – all indicative of excellent nutritional conditions (McCorquodale et al. 1988, 1989; McCorquodale 1991, 1993). Free-ranging Bison on other intermountain ranges have also shown high rates of increase (Van Vuren and Bray 1986; Keiter 1997; Bjornlie and Garrott 2001). There is also no evidence to support the notion that historically Columbia Basin Bison populations were kept at low levels by severe winter weather, as proposed by Daubenmire (1985). After all, Bison thrive in Yellowstone National Park (Keiter 1997; Bjornlie and Garrott 2001) and Wood Buffalo National Park (Carbyn et al. 1998) where winter climates are much more severe than in the Columbia Basin (Urness 1989). Instead, Bison and other ungulates were rare or absent from most of the Columbia Basin because large runs of salmon, and other alternative resources, supported high numbers of native people (Hunn and French 1981), who took their preferred ungulate prey to low levels or local extinction (Kay 1994, 1998, 2002; Chatters 2004).

Native populations and European diseases

It has long been known that native people in the Americas had no immunological resistance to European diseases, but only recently has it been learned that those diseases had a significant impact on native people prior to direct European contact (Dobyns 1983), or how this, in turn, caused abnormal increases in wildlife populations (Neumann 1985; Preston 1996, 1997, 2002; Kay 1998, 2002; Kay and Simmons 2002). European diseases, for instance, preceded Lewis and Clark. The smallpox epidemic of 1780 was especially devastating (Boyd 1985; Trimble 1985), and its aftermath was noted by Lewis and Clark (2: 478-482; 3: 285, 295, 311-312; 6: 81-82, 285, 308). In 1804-1806, Lewis and Clark found four Mandan villages along the middle Missouri but observed that there had been 12 prior to the 1780 epidemic. Similarly, Arikaras villages were reduced from 32 to 2 (Ahler et al. 1991: 57). Thus, if Lewis and Clark had journeyed west in 1775 instead of 1804-1806, they would have met more native people and correspondingly there would have been even less wildlife (Geist 1998: 4-5; Kay 1998, 2002). Furthermore, European diseases may have decimated native populations throughout western North America as early as 1550-1600 (Ramenofsky 1987; Campbell 1990; Kornfeld 1994: 198; Preston 1996, 1997, 2002), which suggests that pre-Columbian wildlife populations were likely much lower than even what Lewis and Clark experienced. Butler (2000), who studied resource depression in the Columbia Basin, reported that high-ranked diet items, such as ungulates, increased only after epidemic diseases decimated native populations ca. 1550. Similarly, Chatters (2004: 72-73) reported that Bison numbers increased only when native populations declined.

Conclusions

Contrary to prevailing paradigms (Lyman and Wolverton 2002; Moore 2002; Wilkinson and Rauber 2002), native people controlled the distribution, abundance, and behavior of wildlife, and large mammals were common only in boundary or buffer zones between warring tribes (Martin and Szuter 1999a, 1999b, 2002, 2004; Farr 2001). It is also clear that Lewis and Clark recognized this phenomenon, for Clark (8: 328) "observed that in the country between the [Indian] nations which are at war with each other the greatest numbers of wild animals are to be found." This pattern can only be explained if native hunters pursued an optimal-foraging strategy and did not employ any effective conservation measures (Alvard 1998b, 2002). Only twice did Lewis and Clark report high wildlife values and encounter

large numbers of native people on the same day. In both cases, native hunters were killing as many animals as possible (3: 176, 253-255). Moreover, Lewis and Clark were only able to complete their journey because of the food, horses, and above all else, knowledge that they received from native people. There were no unnamed streams, there were no unnamed mountains, and there was no wilderness (Kay and Simmons 2002). As noted by Lewis and Clark, the West was even more densely populated prior to the smallpox pandemic that decimated native people in 1780.

These data have important implications for anthropology and archaeology, as well as other disciplines. Most anthropological subsistence models, for instance, incorporate the view that native people harvested ungulates at or near sustained yield levels, yet these and other data do not support that assumption (Kay and Simmons 2002). Similarly, cultural or religious beliefs are often invoked to explain how aboriginal peoples interacted with their environment (Krech 1999), yet irrespective of what the 40 or so native groups encountered by Lewis and Clark believed, or said they believed, the ecological patterns were identical, at least regarding large mammals (see Figure 1). This is similar to what Jerozolimski and Peres (2003) reported for modern subsistence hunters in South America, where neither ethnicity nor culture slowed the depletion of game stocks. Finally, these data support the hypothesis that native people were keystone predators, who once structured entire ecosystems (Kay 1998, 2002; Kay and Simmons 2002); i.e., ecologists need to abandon the myth of once abundant wildlife and instead recognize that unhunted ungulate populations are outside the range of historical variability.

Acknowledgments

This research was supported by a grant from Utah State University and a book contract from Oxford University Press. Susan Durham conducted the smoothing-spline analyses. Fred Wagner, William Preston, Paul Martin, Cliff White, Valerius Geist, Richard Keigley, and Randy Simmons reviewed earlier drafts of this manuscript, as did three anonymous reviewers.

Elsinger, M., E. Burrell, N. deBruyn, K. Tanasichuk, and K. Timoney. 2007. The influence of air pollution on corticolous lichens near the Strathcona Industrial Area, Alberta. Canadian Field-Naturalist 121(1): 17–23.

Lichens that grow on the bark of mature trees were studied at 35 sites along an air pollution gradient east of Edmonton, Alberta. Data on species composition, richness, and cover were recorded in October 1999 in a matrix of sites that extends from a known source of pollutants (the Strathcona Industrial Area) east across Strathcona County. Air pollution is affecting the corticolous lichen community. Lichen species richness and total cover increased with distance from the pollution source. Species richness in areas distant from pollution was roughly twice that in areas near the Strathcona Industrial Area. *Xanthoria fallax* and *Phaeophyscia orbicularis* were the most pollution tolerant lichens. *Xanthoria hasseana, Ochrolechia arborea, Physcia adscendens, Parmelia sulcata,* and *Melanelia albertana* were rare or absent near the pollution source and common in more distant areas. Most of the 15 species assessed were sensitive to air quality to some degree. Some lichens near the refineries and in Sherwood Park showed abnormal coloration and poor thallus integrity indicative of stress. We discuss implications for human health.

Key Words: corticolous lichens, air pollution, health, refineries, vehicle emissions, Alberta.

Lichens are well-known indicators of air quality. While most lichen biomonitoring studies have been conducted in Europe and the United States, there is a growing body of such studies in Canada. In western Canada, 49 lichen species have been used to study general air pollution, while 39, 23, and 18 species have been used to monitor sulphur dioxide, photochemicals, and fluoride, respectively (Thormann 2006). Lichens have proven useful to characterize the concentrations and deposition patterns of air pollutants over large areas, particularly for metals, sulphur, and nitrogen compounds (Enns 2001*).

The fungal and algal partners of the lichen symbiosis live in a delicate balance. Any pollutant that affects the well-being of either partner affects the lichen as a whole (Brodo et al. 2001). Sensitivity to air pollution is related to several features of lichens. They obtain nutrients only from air and precipitation; they accumulate compounds in their thalli and have inefficient mechanisms of excluding or eliminating wastes, they have no protective epidermis or cuticle, and they are quick to show symptoms of stress (Case 1981*; USGS 2005*).

The concentration and constituents of air pollution vary in time and space. In Alberta, there are several important constituents and sources of air pollution (Alberta Environment 1996*; Alberta Health and Wellness 2003). Sulphur dioxide (SO_2) is released from natural gas processing plants, oil sands facilities, power plants, gas flaring, oil refineries, pulp and paper mills, and fertilizer plants. In Alberta, 42% of SO_2 is emitted from natural gas processing plants (Myrick and Hunt 1998*). Hydrogen sulphide is released from fugitive emissions (leakages) at petroleum refineries, tank farms for unrefined petroleum products, natural gas and petrochemical plants, oil sands plants, sewage treatment plants, kraft pulp and paper plants, and animal feedlots. Natural sources include sulphur hot springs and some wetlands and lakes.

Nitrous oxides are produced from high temperature combustion of natural gas, coal, oil, and gasoline. Nitrogen dioxide (NO_2) is a pungent toxin. Ozone near ground level comes from reaction of nitrous oxides and volatile organic compounds in the presence of sunlight and from transport of upper atmosphere ozone down to ground level. Ozone levels are generally lower in urban and polluted areas as ozone is destroyed by nitric oxide (NO). Hydrocarbons come from a variety of industrial and natural sources. The most abundant hydrocarbon in the Earth's atmosphere is methane, a potent greenhouse gas. Reactive hydrocarbons such as alkenes, alkynes, and aromatics are toxic to humans and other animals and vegetation. They react with nitrous oxides in the presence of sunlight to form ozone.

Particulates come from a variety of sources (typically combustion) and can act as carriers for biologically active metals and combustion products. Particulate monitoring is based on the mass of particles filtered per m^3 of air; PM_{10} and $PM_{2.5}$ refer to particles <10 µm and <2.5 µm respectively. In Alberta, the ratio of $PM_{2.5}$: PM_{10} in recent years has ranged from 0.52 to 0.59 (Pollution Watch 2006*).

Alberta is the largest emitter of air pollutants in Canada, with a 2005 release of 1.339 billion kg, 28.4% of the national total, an increase of 62% over its 2002 pollutant release (Pollution Watch 2006*). Among the criteria air contaminants that affect human and ecosys-

tem health, Alberta released 412.8 million kg of sulphur dioxide and 403.9 million kg of oxides of nitrogen in 2005 (Pollution Watch 2006*).

Lichens can be harmed by a variety of air pollutants, including sulphur dioxide, sulfuric and nitric acids, ozone, hydrocarbons, fluorides, and metals such as copper, lead, and zinc (Brodo et al. 2001). Sulphur dioxide impacts on lichens have been noted in Europe since the early 19th century (Simonson 1996*) and can cause decreased species richness, diversity and vitality (Case 1981*). Pollution-tolerant lichens may exhibit increased cover in polluted areas because of decreased competition with more sensitive species, such as *Melanelia albertana* (Muir and McCune 1988; Forest Health Highlights 1994*). Comparative study of the lichens in an urban or industrial area with those distant from pollution can provide a good indicator of air quality.

Our objective was to determine if there are spatially detectable effects on the lichen communities of mature tree bark within and downwind of pollution sources. We focused on the corticolous lichen species that grow on Balsam Poplar (*Populus balsamifera*) and Trembling Aspen (*Populus tremuloides*) trunks.

Study Area

The study area and the Strathcona Industrial Area ("Refinery Row", Figure 1) are located east of Edmonton, Alberta. Refinery Row contains a large group of refineries and other industrial plants and is downwind of Edmonton. Sherwood Park, Fort Saskatchewan, and rural Strathcona County are downwind of Refinery Row. Major sources of air pollution from Refinery Row are industrial plants and vehicle emissions (Alberta Environment 1997*).

Methods

Study sites spanned an area roughly 28 km east-west and 14 km north-south downwind (east) of the primary pollution source in the Strathcona Industrial Area. Study sites were located in naturally forested areas both public and private. Two crews of two people each sampled a total 35 sites in mid-October 1999. Only mature trees with diameters >20 cm at breast height were sampled. Balsam Poplar was the preferred tree as its rough bark afforded abundant microsites for lichens. Aspen were also sampled. Prior to sampling, we learned to recognize a subset of the lichen flora. We focused on 15 taxa readily identifiable in the field.

At each site, we chose the four trees with the highest lichen cover. These trees had rough or fissured bark and were usually the largest and oldest trees present. Our data indicate average maximum cover rather than average cover. For each tree, we noted the tree species and diameter at breast height and determined the percent cover of each lichen species growing on the bark in the zone 0.5-1.5 m above the ground. Locations were recorded with a GPS unit. Lichen names follow Brodo et al. (2001).

For each site, we determined mean percent cover for each species and all combined species and the total number of species. Lichen cover and location data were analysed statistically. While air pollutants originate from the entire industrial area, and from Edmonton in general, we defined a single pollution source point to quantify distance from source. That point was defined as the junction of Baseline Road and 34th Street on the west side of Refinery Row. Distances from each site to the defined pollution source were determined in a geographic information system.

Results

Of the 15 taxa of corticolous lichens assessed, six tended to be common and dominant and nine uncommon and non-dominant (Tables 1, 2). Lichen species richness and cover increased with distance from the pollution source (Figure 2). Relationships with distance were strongest for species richness and for non-dominant species cover (Table 3). Both richness and cover appeared to rise exponentially with distance. Species richness and total cover increased gradually from west to east over the first 15-20 km of the pollution gradient, then increased more rapidly (Figure 3). Minimum richness and cover were found in the northwestern sites. Richness and cover continued to rise over the gradient indicating that air quality influenced the lichen community across the entire area. Some lichens near the refineries and in Sherwood Park showed abnormal coloration (e.g., pale colors, or pinkish hues) and poor thallus integrity (partly disintegrated thalli) indicative of stress.

Of the six dominant species, all but one species (*Phaeophyscia orbicularis*) increased in cover with dis-

tance from the pollution source (Figure 4). *Xanthoria fallax* and *Phaeophyscia orbicularis* were the most hardy lichens, present in virtually all sample sites. *Xanthoria hasseana* and *Ochrolechia arborea* increased appreciably in cover with distance from the refineries. *Physcia adscendens, Parmelia sulcata,* and *Melanelia albertana* were rare or absent near the pollution source and common in more distant areas. Similarly, *Flavopunctelia flaventior, Hypogymnia physodes, Usnea* sp., *Evernia mesomorpha,* and *Arthonia patellulata* were rare to absent near the refineries. Most species were sensitive to air quality to some degree.

Discussion

Lichens are good bioindicators of air quality in the region. There were clear trends of decreasing cover and richness with increasing proximity to Refinery Row.

TABLE 3. Spearman rank correlations of distance from pollution source with lichen species richness and cover ($n = 35$; all correlations were significant at $P<0.001$).

Correlations (r)	Distance
Species Richness	0.61
Total Cover	0.57
Dominant Species Cover	0.51
Non-dominant Species Cover	0.67

The pattern of decreasing lichen cover and species richness with increasing levels of air pollution is consistent with that documented in large Canadian cities such as Winnipeg, Manitoba (Stringer and Stringer 1974), and Hamilton, Ontario (McCarthy and Vaughan 2004*).

The results support those of Muir and McCune (1988) and van Dobben and ter Braak (1999) who found that

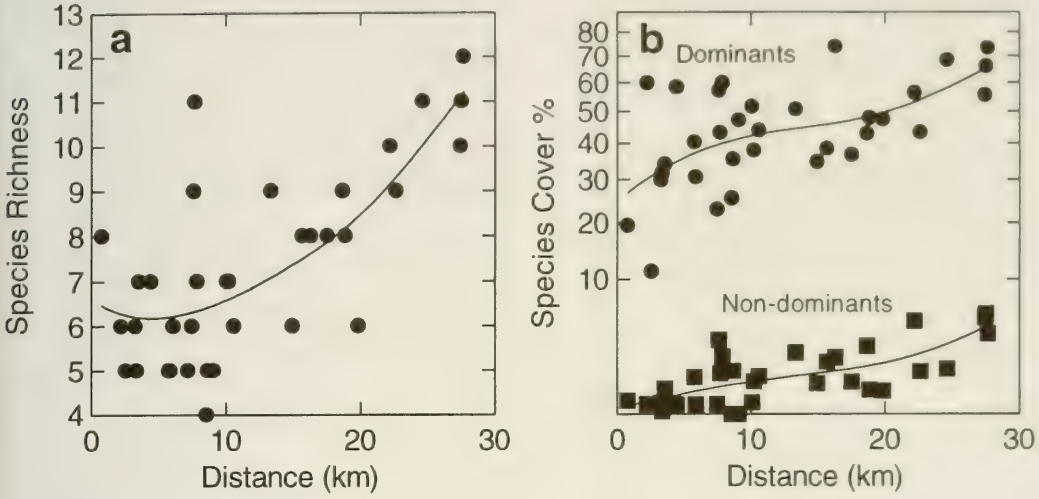

FIGURE 2. Lichen species richness (a) and total cover (b) in relation to distance from the pollution source. Line is a distance-weighted least squares regression, tension 1. The species cover y-axis is transformed, power 0.5.

air pollution reduces species richness, decreases total cover, alters species composition, and amplifies the presence of pollution-tolerant lichen species. *Phaeophyscia orbicularis* is a pollution-tolerant species; *Xanthoria polycarpa* (a close relative of *X. hasseana*) and *Ochrolechia* are moderately to significantly sensitive to SO_2 pollution (van Dobben and ter Braak 1999).

Several factors may have influenced the results. Lichen species richness differs among host tree species (Muir and McCune 1988). This influence was minimized by our choice of only Balsam Poplar and Trembling Aspen. Exposed and isolated tree patches may have had lower lichen cover and richness in part because isolated trees are more exposed to air pollutants than are forest trees (Smith 1981). Microsite differences may have affected our findings at some sites. The choice of four mature trees with maximum lichen cover at each site should have minimized differences due to unsuitable substrates (such as smooth bark on rapidly growing trees).

As the pollution originates from several sources, including refineries, local vehicle emissions, and urban combustion, distance from a single point source is a simplification. Most of the sites were near roadways and were likely affected by vehicle emissions. Differences in traffic load may have contributed to the variability in the lichen communities. Strathcona County official weekday traffic counts during 1997 and 1998 for arterial roads in the vicinity of Refinery Row ranged from 21 120 to 36 130 vehicles per day. In contrast, traffic counts near the easternmost rural sites ranged from 82 to 1252 vehicles per day (mean 326, $n = 15$).

A combination of industrial, vehicular, and urban emissions results in lower air quality in the Refinery Row area. Winds distribute and disperse the pollutants in complex ways evident in Figure 3. Air quality monitoring in Fort Saskatchewan, about 20 km north-northeast of Refinery Row, found that sulphur dioxide levels rose significantly (by 21%) when winds were from the south-southwest (Albert Health and Wellness 2003), a fact attributed to wind dispersal of pollutants from east Edmonton.

Air pollution is a serious health concern of millions of people worldwide and has been linked with higher rates of allergies and respiratory and cardiovascular diseases (Health Canada 2004*). Numerous epidemiological studies have demonstrated a link between ambient air pollution and adverse human health effects (Alberta Health and Wellness 2003). It can be difficult, however, to establish a causal relationship between exposure to a specific contaminant and a resultant health effect. Lack of a demonstrated causal link between a pollution source and human health does not mean that no link exists. Indeed, precautionary common sense should assume there may be a link until the required controlled studies are conducted. Sensitive bioindicators such as lichens can be used in the interim to inform public policy.

While air pollution effects upon the lichen communities are evident, levels of local monitored air quality parameters appear to be within Alberta government guidelines. This should perhaps not come as a surprise. Air quality guidelines are based in part upon science and in part upon what is feasible within the socioeconomic objectives of stakeholders (Long Fu, Alberta Environment, personal communication, 9 February 2006). Our results indicate that current air quality guidelines are inadequate for the protection of the lichen communities.

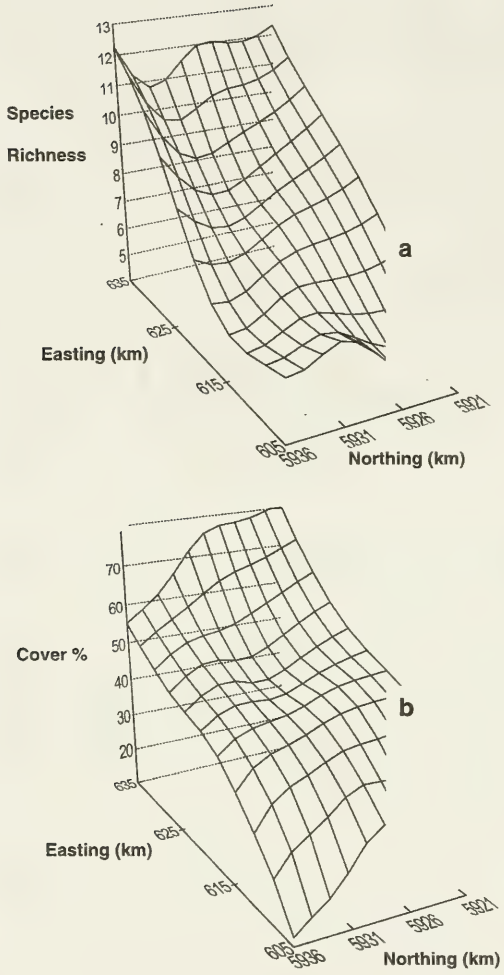

FIGURE 3. Lichen species richness (a) and total cover (b) in relation to location. The surface is a distance-weighted least squares regression, tension 1. The view is from the northwest towards the southeast. Coordinates are in Alberta provincial 10TM projection.

Despite widespread public concern, independent, journal-published studies of the relationships between air pollution and human health downwind of the Strathcona Industrial Area have not been conducted to date. Alberta Health (1996) conducted a small, short-term study of respiratory disease rates in Strathcona County and Fort Saskatchewan. They were unable to detect above normal rates of mortality and hospital admissions but observed above normal rates of physician visits for asthma. As a large human population is needed for robust statistical analyses, the statistical power of that study was limited. Ozone, acid aerosols, nitrogen oxides, volatile organic compounds, and particulates may be responsible for adverse health effects at current levels of exposure (Alberta Health 1996).

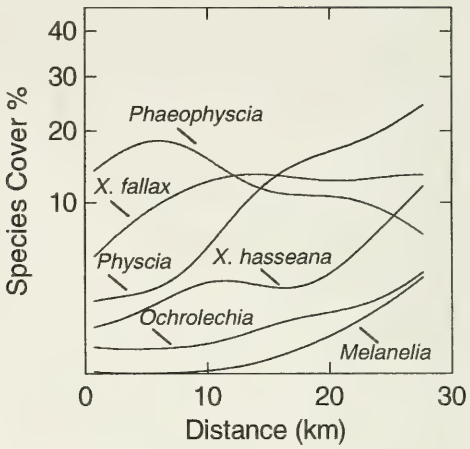

FIGURE 4. Lichen cover in relation to distance from the pollution source for the six dominant species. Line is a distance-weighted least squares regression, tension 1. The species cover y-axis is transformed, power 0.5.

As regards particulate matter, epidemiologic studies have been conducted that reveal a coherence and consistency of effects across a range of health outcomes and independent studies in different settings (Dockery and Pope 1994). Weighted mean increases in daily mortality of 1.0% (all causes of death), 1.4% (for cardiovascular deaths), and 3.4% (for respiratory deaths) for each 10 $\mu g/m^3$ increase in PM_{10} have been established (Dockery and Pope 1994). In Fort Saskatchewan, Alberta Health and Wellness (2003) observed a 95th percentile $PM_{2.5}$ outdoor concentration of 13.2 $\mu g/m^3$, corresponding to a PM_{10} concentration of ~ 23.3 $\mu g/m^3$ (when the 2005 ratio of 0.568 for $PM_{2.5}$ to PM_{10} in Alberta is applied). Such a concentration would be expected to cause an increased daily mortality of 2.3% for all causes of death, 3.3% for cardiovascular deaths, and 7.9% for respiratory deaths (Dockery and Pope 1994).

Political decisions on regional air quality issues have to date supported business as usual. As Strathcona County Councillor Alan Dunn sees it (personal communication, 16 February 2006), "we politicians spend too much time sticking our heads in the sand." Councillor Glen Lawrence (personal communication, 16 February 2006) supports an improved air quality monitoring program. Both Councillors agree that protection of air quality and human health must begin to play a central role in future decisions regarding development.

Rates of death from asthma in Canada increased sharply from 1970 through the early 1980s and subsequently remained high through the 1980s (Wilkins and Mao 1993). In Alberta from 1980 to 1988, hospital admissions for asthma increased 35% for children younger than 15 years and increased 48% for Albertans 15-34 years of age. Of all provinces in Canada, Alberta has the

highest death rate for asthma in people younger than 35 years of age (Wilkins and Mao 1993).

As sentinels of air quality, the lichens are telling us that all is not well in the air east of Edmonton, Alberta.

The Hepatic Flora and Floristic Affinity of Hepatics Around Takakia Lake, Queen Charlotte Islands, British Columbia

Won Shic Hong

Department of Biology, University of Great Falls, Great Falls, Montana 59405-4934 USA.

Hong, Won Shic. 2007. The hepatic flora and floristic affinity of hepatics around Takakia Lake, Queen Charlotte Islands, British Columbia. Canadian Field-Naturalist 121(1): 24–28.

The known hepatic flora of the Takakia Lake area consists of 66 species, 2 subspecies, and 2 varieties, in 30 genera and 18 families. Thirty-seven taxa (51.8%) of the total 70 taxa present are boreal in distribution. Seven taxa (10.1%) are western North American and Amphi-Pacific elements. This clearly demonstrates that the greatest diversity of western North American hepatics occurs between 45°–55°N and between 120°–135°W which includes the lake (Hong 1988). Other distribution patterns include a taxon which is a North American boreal endemic and one which is a North American temperate endemic; two are cosmopolitan and disjunct montane; three are circumtemperate and circum-montane; six are temperate disjunct; eight are arctic and alpine; fourteen are boreal disjunct and twenty-three are circumboreal.

Key Words: Hepatics, Takakia Lake, Queen Charlotte Islands, British Columbia.

Takakia Lake is a high-elevation lake located on the northwestern part of Moresby Island, one of 150 islands that comprise the Queen Charlotte Islands (31°54'–54°13'N to 130°58'–133°06'W). The lake (52°55'N and 132°03'W) is situated at almost 650 m above sea level just at the tree line and measures 1.25 km in length and 0.75 km in width.

Before the discovery of the rare bryophyte *Takakia lepidozioides* (on soil, partly covering rocks) by Persson in 1958, the lake was unnamed (Figure 1).

The first report of *Takakia lepidozioides* was made by Hattori and Inoue (1958) using the specimen collected by Takaki in 1951 at 2400 m altitude on Mt. Shirouma, Japanese Alps, middle Japan. They described this species as a member of hepatics and placed it under the new order Takakiales, and the new family, Takakiaceae, based on sterile materials. Later the species was found in Borneo (Hattori 1963) and another species of *Takakia, T. ceratophylla,* was found in the Himalayas (Grolle and Long 2000).

For many years after the discovery of this species, many bryologists sought sporophytes of *Takakia.* Finally in 1990, Smith and Davidson (1990) reported sporophytes in the central Aleutian Islands and clarified the systematic position of *Takakia* as a moss with links to Andreaeopsida, previously suggested by Mizutani (1974) and Murray (1988).

The surrounding hills of Takakia Lake are mainly noncalcareous substrates which receive almost 5 000 mm annual precipitation; they are dominated by Sitka Spruce *(Picea sitchensis)* and Western Hemlock *(Tsuga heterophylla).* There are many suitable moist areas that favor the growth of hepatics, especially alpine meadows that have developed on north-exposed slopes of the lowest part of the alpine region at the eastern end of the lake.

The most common herbs are *Senecio triangularis, Mitella pentandra, Habenaria saccata, Vahlodea atropurpurea, Eriophorum angustifolium, Erigeron peregrinus, Veratrum eschscholtzii, Saxifraga punctata, Cardamine umbellata, Epilobium delicatum, Tiarella trifoliata, Dodecatheon jeffreyi,* and *Heracleum lanatum* (Calder and Taylor 1968). Hepatics are abundant along a small stream running through the meadows.

In 1969, V. J. Krajina and his colleagues of Department of Botany, University of British Columbia, proposed that the provincial government preserve the lake as an ecological reserve, citing the need to protect representative ecosystems, rare genetic resources, and outstanding biological phenomena in a remote alpine setting. The proposal was considered by the government; however, it was never approved.

The lake flows into Moresby Lake, which feeds a turbine and supplies electric power to Moresby Island and the southern part of Graham Island. In 1997, Queen Charlotte Power Corporation from Vancouver, British Columbia, proposed the drilling of holes into Takakia Lake to supply water for more electric power, thus reducing the water level of the lake. Any such drawdown of the lake would destroy the sensitive habitat of most of its endangered or threatened species of plants, especially hepatics, mosses and lichens.

It is necessary to preserve the lake's constant water level to protect this unique representative ecosystem of an alpine lake, rare genetic resources, and outstanding biological phenomena in a remote, clear, and unpolluted lake. Hepatics especially are so sensitive to humidity that if water were drained from the lake during their vigorous growing season (summer), they would die or would disappear. Such phenomena have been clearly demonstrated by the cutting of old-growth forests around various lakes or along the stream banks resulting in reduced water availability.

Along the shore line of Takakia Lake, there are numerous rare species vulnerable to water level change,

FIGURE 1. Takakia Lake in Queen Charlotte Islands (after Provisional Resource Description & Analysis. South Moresby/ Gwaii Haanas National Park Reserve 1990)

including *Takakia lepidozioides* (under Musci), and the following hepatics: *Anastrophyllum assimile, Anthelia julacea, Diplophyllum imbricatum, D. plicatum, Gymnomitrion pacificum, Herbertus sakuraii, Hygrobiella laxifolia, Kurzia sylvatica, Lepidozia filamentosa, Marsupella alpina, M. boeckii, Pleurocladula albescens,* and *Pleurozia purpurea.*

In order to secure luxurious growth and maintenance of its biodiversity of bryophytes through ample moisture, a constant water level should be maintained in Takakia Lake.

The author made collecting trips during the summers of 1999, 2000 and 2001. Voucher specimens have been deposited at the herbarium of the University of Great Falls, Montana (GFC), with available duplicates in the herbarium of University of Cincinnati (CINC). This report is based on author's collections, specimens borrowed from Chicago Natural History Museum (F), Swedish Museum of Natural History (S), and University of British Columbia (UBC) and literature reports from the following: Persson (1958); Miller (1968); Schofield (1968); Hong (1992, 1993). In general, nomenclature follows Stotler and Crandall-Stotler (1977) and Grolle and Long (2000). Only one representative specimen of each taxon is cited. Genera and species are listed alphabetically.

Annotated Checklist of the Liverworts of Takakia Lake Area

Anastrophyllum (Spruce) Steph.
- *assimile* (Mitt.) Steph. – wet cliff crevices. (Persson 1958)

Anthelia (Dumort.) Dumort.
- *julacea* (L.) Dumort. – wet rocks. 00-397.
- *juratzkana* (Limpr.) Trevis – humus on rocks. 99-179.

Barbilophozia Loeske
- *floerkei* (F. Weber & D. Mohr) Loeske – shaded rocks. 00-400.
- *hatcheri* (A. Evans) Loeske – partially shaded ledge. Persson s.n.(S).
- *kunzeana* (Huebener) Müll. Frib. – moist ledge. Schofield 25158 (F).
- *lycopodioides* (Wallr.) Loeske – shaded, moist ledge. Persson s.n. (S).

Bazzania Gray
- *pearsonii* Steph. – rocks and soil. Schofield 25158 (UBC). (Schofield 1968).
- *tricrenata* (Wahlenb.) Lindb. – bark, decayed wood, and soil. 99-256.

Blepharostoma (Dumort.) Dumort.
- *trichophyllum* (L.) Dumort. subspecies *trichophyllum* – shaded, moist soil, rocks and decayed wood. 99–180

Calypogeia Raddi
- *azurea* Stotler & Crotz. – shaded, decayed wood and moist soil. (Persson 1958).
- *integristipula* Steph. – shaded, decayed wood and moist soil. 01-206.
- *neesiana (C.* Massal. & Carestia) Müll. Frib. – shaded, decayed wood and moist soil. 99-208.

Cephalozia (Dumort.) Dumort.
- *ambigua C.* Massal. – shaded, decayed wood and moist soil. 015-216.
- *bicuspidata* (L.) Dumort. – shaded, decayed wood 99-195.
- *leucantha* Spruce – shaded, decayed wood. 01-230.
- *lunulifolia* (Dumort.) Dumort. – shaded decayed wood. wet rocks and stream banks. 99-180.
- *macounii* (Austin) Austin – decayed wood and moist soil. 99-182.

Diplophyllum (Dumort.) Dumort.
- *albicans* (L.) Dumort. – shaded, decayed wood, soil and rocks. 99-170.
- *imbricatum (M. A.* Howe) Müll. Frib. – rocks. (Persson 1958; Hong 1993).
- *plicatum* Lindb. – shaded, decayed wood and thin soil over wet rocks. (Persson 1958).
- *taxifolium* (Wahlenb.) Dumort. – shaded ledge. 99-253.

Eremontus Lidnb. & Kaalaas in Pearsson
- *myriocarpus* (Carrington) Pearson – wet rocks. Godfrey and Schofield (1979).

Frullania Raddi
- *nisquallensis* Sullivant – branches and bark, decayed wood and humus on rocks. 99-175.

Gymnomitrion Corda
- *concinnatum* (Lightf) Corda – rocks. Schofield 24279 (UBC).
- *obtusum* Lindb. – acid rocks. 99-253.
- *pacificum* Grolle – wet rocks. (Persson 1958; Schofield 1968).

Herbertus Gray
- *aduncus* (Dicks.) Gray – bark and soil. Schofield 24788 (UBC).
- *sakuraii* (Warnst.) S. Hatt. – bark and soil. 99-194.

Hygrobiella Spruce
- *laxifolia* (Hook.) Spruce – peat bog. Schofield 25058 (UBC). (Schofield 1968).

Jungermannia L.
- *hyalina* Lyell – wet soil or soil covered rocks. Persson s.n. (S). (Váña & Hong 1999).
- *obovata* Nees – shaded, decayed wood and wet soil near stream. 99-245.
- *pumila* With. – wet rocks near stream. 99-266a.

Kurzia G. Martens
- *sylvatica* (A. Evans) Grolle – decayed wood and soil. 99-165.

Lepidozia (Dumort.) Dumort.
- *filamentosa* (Lehm. & Lindenb.) Lindenb. – shaded, decayed wood (Persson1958)
- *reptans* (L.) Dumort. – shaded, decayed wood. 99-255.

Lophozia (Dumort.) Dumort.
- *incisa* (Schrad.) Dumort. – shaded, moist decayed wood. 99-285.
- *longiflora* (Nees) Schiffn. [= *ventricosa* var. *longiflora* (Nees) Macoun;
- = *guttulata* (Lindb. & Arm.) Schiffn.] – decayed wood and soil. 99-255.
- *opacifolia* Culm. ex Meyl. – wet soil. 00-402.
- *sudetica* (Nees) Grolle – wet outcrop. 00-394.
- *ventricosa* (Dicks.) Dumort. – decayed wood and soil. 99-218.
- *wenzelii* (Nees) Steph. – humus on decayed wood. 00-475.

Marsupella Dumort.
- *alpina* (Gottsehe ex Husn.) Bernet. – rocks. 99-253.
- *boeckii* (Austin) Kaal. – rocks. 99-179 (Hong 1992).
- *emarginata* (Ehrh.) Dumort. – moist soil near stream and wet rocks. 99-218.
- var. *aquatica* (Lindenb.) Dumort. – submerged. 99-168. This variety is very abundant, covering wet rocks in the streamlets of the entire meadow, disdistinguished from var. *emarginata* by its rigid texture, black color, shallow-

ly bilobed leaves with narrow sinus and bulging trigones. Many rhizoids are distinctly purplish.

Moerckia Gottsche
blyttii (Moerch) Brockm. – wet soil near stream. 00-479.

Mylia Gray
taylorii (Hook.) Gray – shaded, decayed wood and moist soil. 99-191.

Nardia Gray
compressa (Hook.) Gray – seep margins of stream. 99-198.
geoscyphus (De Not.) Lindb. – moist soil and wet rocks near stream. 00-411.
japonica Steph. – soil. Schofield 25028 (UBC).
scalaris Gray – moist soil and wet rocks near stream. 99-266b.

Pellia Raddi
endiviifolia (Dicks.) Dumort. – wet rocks and soil near stream. 99-266a.
epiphylla (L.) Corda – moist soil near stream. 01-190.
neesiana (Gottsche) Limpr. – moist soil near stream. 99-200.

Plagiochila (Dumort.) Dumort.
porelloides (Torrey ex Nees) Lindenb. – moist soil and decayed wood. 99-214.

Pleurocladula Grolle
albescens (Hook.) Grolle – moist soil near stream. 01-196. (Persson 1958).

Pleurozia Dumort.
purpurea Lindb. – peat bog. Schofield 25058 (UBC). (Schofield 1968)

Ptilidium Nees
californicum (Austin) – bark and decayed wood. 99-175.

Radula Dumort.
auriculata Steph. – shaded, wet cliffs and bark. Schofield 25060 (UBC). Schofield (1968).
obtusiloba subsp. *polyclada* (A. Evans) S. Hatt. – wet rocks, soil and humus on decayed wood. 00-464.

Riccardia Gray
latifrons (Lindb.) Lindb. – shaded, decayed wood and peat. 00-433.
palmata (Hedw.) Carruth. – shaded, decayed wood. 99-255.

Scapania (Dumort.) Dumort.
americana Müll. Frib. – wet soil near stream. 01-68.
bolanderi Austin – bark, decayed wood and soil. 99-170.
paludosa (Müll. Frib.) Müll. Frib. – wet rocks near stream. 01-104.
undulata (L.) Dumort. – shaded, decayed wood and wet soil near stream and waterfalls. 99-256. Many collections show distinct reddish-blackish color due to light exposure and are superficially similar to S. *uliginosa*.
var. *oakesii* (Austin) Müll. Frib. – wet rocks near stream. 01 -104.

Tritomaria Schiffn. ex Loeske
quinquedentata (Huds.) H. Buch – shaded rocks. 99-214.

Geographical Relationships

The known hepatic flora of Takakia Lake area consists of 70 taxa; twelve different distributional elements (Table 1) are presented. The world distribution categories follow those given in Belland et al. (1992) and Hong (1999).

1. *Cosmopolitan element*s (2 taxa 3.0%). The taxa of this group are not restricted to major vegetational biomes – arctic, boreal, temperate and tropical zones.

TABLE 1. The floristic affinities of the Hepaticae of Takakia Lake.

Elements	Number of hepatics	(%)
1. Cosmopolitan	2	(3.0)
2. Circumboreal	23	(32.2)
3. Boreal disjunct	14	(19.6)
4. North American boreal endemic	1	(1.5)
5. Circumtemperate	3	(4.6)
6. Temperate disjunct	6	(8.5)
7. North American temperate endemic	1	(1.5)
8. Circum-montane	3	(4.6)
9. Disjunct-montane	2	(3.0)
10. Arctic and alpine	8	(11.4)
11. Amphi-Pacific	5	(7.1)
12. Western North American endemic	2	(3.0)
Total	70	(100.0)

Jungermannia hyalina and *Riccardia palmata* belong to this element.

2. *Circumboreal elements* (23 taxa, 32.2%). Almost one-half of the hepatics around the lake belong to the boreal elements (51.8%), and are predominantly (32.2%) circumboreal. The latter are widespread throughout the Northern Hemisphere within the boreal biomes. Representative taxa are *Anastrophyllum assimile, Barbilophozia hatcheri*), *B. lycopodioides, Blepharostoma trichophyllum, Calypogeia integristipula, C. neesiana, Cephalozia lunulifolia, C. macounii, Diplophyllum taxifolium, Gymnomitrion concinnatum, Jungermannia pumila, Lepidozia reptans, Lophozia incisa, L. longiflora, L. ventricosa, L. wenzelii, Marsupella emarginata* and var. *aquatica, Nardia compressa, N. geoscyphus, Plagioichila porelloides, Riccardia latifrons* and *Tritomaria quinquedentata.*

3. *Boreal elements* (14 taxa, 19.6%). The species of this group have major gaps in their world distribution. Representative taxa are *Barbilophozia voerkei, Bazzania tricrenata, Cephalozia leucantha, Diplophyllum albicans, Gymnomitrion obtusum, Hygrobiella laxifolia, Moreckia blyttii, Mylia taylori, Nardia scalaris, Pellia endiviifolia, P. epiphylla, Pleurozia purpurea, Scapania undulate* and var. *oakesii.*

4. *North American boreal endemic elements* (a taxon, 1.5%). Only one taxon, *Diplophyllum imbricatum*, belongs to this element.

5. *Cicumboreal element* (3 taxa, 4.6 %). The taxa of this group; are widely distributed in the temperate forests of the Northern Hemisphere including Europe. Asia and eastern and western North America. Examples are *Calypogeia azurea, Cephalozia bicuspidata,* and *Pellia neesiana.*

6. *Temperate disjunct elements* (6 taxa, 8.5%). The taxa of this group occur in the same region as the above group; however, they are absent from one or two of the above regions. Examples are *Gymnomitrion pacificum, Herbertus aduncus, Kurzia sylvatica, Lepidozia fila-*

mentosa, Plagiochila semidecurrens, and *Radula auriculata.*

7. *North American temperate endemic elements* (a taxon, 1.5%). The taxon is restricted to temperate forest of North America. *Scapania americana* belongs to this group.

8. *Circum-montane elements* (3 taxa, 4.6%). The taxa in this element are *Bazzania pearsonii, Marsupella alpina* and *M. boeckzii.*

9. *Disjunct-montane elements* (2 taxa, 3.0 %). Only *Jungermannia obovata* and *Scapania paludosa* belong to this element.

10. *Arctic-alpine elements* (8 taxa, 11.4%). The taxa restricted to arctic and alpine areas. Examples are *Anthelia julacea, A. juratzkana, Barbilophozia kunzeana, Cephalozia ambigua, Eremontus myriocarpus, Lophozia opacifolia, L. sudetica* and *Pleurocladula albescens.*

11. *Amphi-Pacific elements* (5 taxa, 7.1%). The taxa of this group occur in the Northern Pacific coast of Asia (from Kamchatka to the northern tip of the Philippines, including southeastern area of China, Formosa, the southern part of Korea and Japan) and North America (from Alaska to California, including the southwestern part of Yukon, Idaho and western part of Montana). Examples are *Diplophyllum plicatum, Herbertus sakuraii, Nardia japonica, Ptilidium californicum,* and *Scapania bolanderi* (see Hong 1988).

12. *Western North American endemic elements* (2 taxa, 3.0%). The taxa of this group are restricted to the western part of North America, including *Frullania nisqualensis* and *Radual obtusiloba* subsp. *polyclada.*

Acknowledgments

The author thanks E. McAllister, R. McDowell, D. Lund, A. Alt, Rv. J. Sikora, A. Graetzenberg, V. Matthews, and Sisters M. Benoit and K. Nealen for their assistance. I am also grateful to W. Schofield for suggestions and helpful comments on the original manuscript.

Comparison of Scales, Pectoral Fin Rays and Opercles for Age Estimation of Ontario Redhorse, *Moxostoma*, Species

Scott M. Reid

Watershed Science Centre, Trent University, Peterborough, Ontario K9J 7B8 Canada

Reid, Scott M. 2007. Comparison of scales, pectoral fin rays and opercles for age estimation of Ontario Redhorse, *Moxostoma*, species. Canadian Field-Naturalist 121(1): 29–34.

Opercle based age estimates of four redhorse species (*Moxostoma anisurum*, *M. carinatum*, *M. macrolepidotum* and *M. valenciennesi*) were compared with those from two structures that can be obtained non-lethally (scales and pectoral fin rays). For all species, age estimates from scales were significantly lower than those obtained from fin rays and opercles. After ages 4 to 5, age estimates from scales were consistently lower than those from the opercle. Overall differences between age estimates from fin rays and opercles were only detected for *M. anisurum*. For all species, age estimates from fin rays were consistently lower than opercles after ages 12 to 15. Closer agreement among different structures was identified for populations of *M. macrolepidotum* comprised of younger individuals. Maximum ages reported for Ontario populations were higher than those previously reported across the species' ranges, reflecting either geographic differences in growth and longevity, or the historical use of scales for age estimation.

Key Words: redhorse, *Moxostoma*, age interpretation, calcified structures, Ontario.

Redhorses (*Moxostoma* spp.) are relatively large, laterally compressed and superficially similar suckers (Scott and Crossman 1979). In southern Ontario rivers, redhorse comprise a large proportion of fish biomass (Cooke and Bunt 1999). However, like many non-sport fish species in Canada, little is known about redhorse life history (Cooke et al. 2005). Of the six redhorse species in Ontario, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) designated the Black Redhorse (*M. duquesnei*) as nationally threatened and the River Redhorse (*M. carinatum*) as a species of special concern (COSEWIC 2005*). These two species and the Greater Redhorse (*M. valenciennesi*) are also imperiled in several neighbouring Great Lakes states (NatureServe 2005*). Recovery efforts for fish species at risk in Canada are limited by a lack of knowledge regarding their ecology, population size and factors that affect distribution and abundance.

Population age information is necessary for determining growth and mortality rates, age at maturity, and understanding the effects of environmental changes. Most redhorse age interpretations have used scales (Meyer 1962; Carlander 1969; Bowman 1970; Hackney et al. 1970; Curry and Spacie 1984; McAllister et al. 1985; Sule and Skelly 1985; Kwak and Skelly 1992; Cooke and Bunt 1999). Compared to fin rays or the opercle, scales typically underestimate age of older catostomids (Chalanchuk 1984). In older fish, annuli may be crowded at the distal edge due to minimal or non-existent scale growth and/or scale edges may be reabsorbed and annuli lost. Annulus formation in Shorthead Redhorse (*M. macrolepidotum*) pectoral fin rays was validated by Harbicht (1990). However, while less likely to underestimate age than scales, fin ray based age interpretations for older redhorse can be less accurate than those from either the opercle or otolith (Huston 1999). Re-absorption of the central part of the fin rays can obscure the first annulus and crowding of annuli in distal portions may occur in older fish, leading to potential errors in age determination (Beamish and Chilton 1977; Quinn and Ross 1982). If the fin ray is cut too far from the body, the core may not be seen or the annulus may be missing (Howland et al. 2004). The primary disadvantage of age estimation based on the opercle or otolith is that the fish must be killed in order to obtain the structure. As well, burnt or cracked otoliths have poor archival properties compared to fin rays (Howland et al. 2004).

Population monitoring of fish species at risk may require non-lethal sampling methods. Method comparisons assist in evaluating which is most efficient, reliable and appropriate for a given population study (Beckman 2002). If similar ages are observed using different structures then the most accessible and easily interpreted should be used (Howland et al. 2004). The objective of this study was to compare opercle based age estimates of four redhorse species (Greater Redhorse, River Redhorse, Shorthead Redhorse and Silver Redhorse (*M. anisurum*)) with age estimates from two structures that can be obtained non-lethally (scales and pectoral fin rays). The opercle was used, instead of the otolith, because it requires less preparation time and provides age estimates that are in close agreement with the otolith (Howlett 1999; Huston 1999).

Methods and Materials

Between 2000 and 2004, redhorse were collected from multiple sites across three southern Ontario drainages: Bay of Quinte (44°6'N, 77°28'W), Grand River (43°6'N, 80°19'W), and Ottawa River (45°39'N,

TABLE 1. Number and size range (total length: TL) of redhorse sampled from the Ottawa River, Bay of Quinte and Grand River drainages in Ontario.

	Greater Redhorse		River Redhorse		Shorthead Redhorse		Silver Redhorse	
Drainage	Number	TL (cm)	Number	TL (cm)	Number	TL (cm)	Number	TL (cm)
Ottawa River	7	51.0–63.5	8	40.0–65.0	51	18.8–55.4	87	15.2–66.0
Bay of Quinte	17	39.2–59.8	18	47.3–73.2	26	38.4–55.6	67	33.8–63.3
Grand River	11	40.3–63.9	1	64.7	37	24.5–53.7	–	–
All	35	39.2–63.9	27	40.0–73.2	114	18.8–55.6	154	15.2–66.0

76°42'W) (Table 1). Sampling occurred either as part of targeted redhorse inventories or Ontario Ministry of Natural Resources (OMNR) fish community sampling programs. Redhorse were collected using gill-nets, hoop-nets or a boat electro-fishing unit. Scales were collected below the dorsal fin above the lateral line on the left side of the fish. The most anterior pectoral fin ray on the left side of the body was removed using wire cutters as close to the body as possible. The opercle, a thin flat bone that covers the gills, was also removed. All structures were placed in a scale envelope to dry.

Two to five scales were pressed onto acetate slides using a roller press and read on a microfiche projector. Pectoral fin rays were embedded in epoxy, sectioned with a low-speed Isomet saw (section width 600 μm) mounted on a slide and polished with 320 and 600 grit wet sandpaper. Opercles were placed in hot water for several minutes to facilitate tissue removal with a toothbrush and then air dried. Fin ray sections and opercles were interpreted using a dissecting microscope and transmitted light. Identification of scale, fin ray and opercle annuli was based on illustrations provided by Chalanchuk (1984), Harbicht (1990) and Marcogliese (1996). Age assignment was based on annulus counts and edge condition data (Casselman 1987). Annuli number and edge condition were assigned without knowledge of fish size or date of collection. Before structures were interpreted, a subsample (~10) of each structure was interpreted with a second experienced reader to improve confidence in annuli identification.

For each species, statistical differences between age estimates based on scale, pectoral fin ray and opercle were tested using Friedman's test and a non-parametric multiple comparisons procedure for ranked data (Zar 1999). Age bias plots (Campana et al. 1995) were constructed to assess age bias from scales and pectoral fin rays compared to opercle bones. Repeatability of age estimates was evaluated by re-interpreting a subset (30 to 50) of each structure within one year of first interpretation. Percent agreement (absolute and ± 1 year) of first and second interpretations was calculated.

Results

For all species, age estimates from scales, fin rays and opercles were not equal (Friedman's test statistic: 31.8 to 134.7; $P < 0.001$). Age estimates from scales were significantly lower than those obtained from either fin rays or opercles (Table 2). After ages 4 to 5, age estimates from scales were consistently lower than those

TABLE 2. Comparisons of redhorse age estimates and repeatability for each aging structure. Statistically different age estimates are indicated by different superscripts (A, B or C).

Structure	Greater Redhorse	River Redhorse	Shorthead Redhorse	Silver Redhorse
Mean age[1]				
Scale	5.9 (2-9)^{A}	7.4 (4-13)^{A}	5.1 (1-10)^{A}	7 (1-11)^{A}
Fin ray	8.7 (4-15)^{B}	11.3 (7-19)^{B}	8.5 (2-18)^{B}	11.4 (2-23)^{B}
Opercle	9.4 (4-20)^{B}	11.6 (6-27)^{B}	8.7 (1-20)^{B}	12.9 (1-27)^{C}
Mean pairwise difference in age estimates[1]				
Scale vs. Fin ray	3.0 (0-8)	3.9 (1-11)	3.7 (0-10)	4.4 (0-15)
Scale vs. Opercle	3.5 (0-11)	4.3 (0-16)	3.9 (0-12)	6.3 (0-22)
Fin ray vs. Opercle	1.4 (0-6)	2.3 (0-9)	1.5 (0-9)	2.4 (0-11)
Percent agreement between structures[2]				
Scale vs. Fin ray	3.4 (13.8)	0 (8.7)	4.3 (17.0)	1.9 (18.1)
Scale vs. Opercle	3.2 (22.6)	8.3 (37.5)	9.4 (27.1)	5.7 (19.0)
Fin ray vs. Opercle	27.3 (63.6)	29.6 (48.1)	30.6 (63.1)	28.7 (54.3)
Percent agreement between first and second readings[2]				
Scale	74 (100)	72 (89)	60 (74)	48 (68)
Fin ray	85 (100)	80 (94)	87 (98)	64 (93)
Opercle bone	64 (91)	96 (100)	54 (88)	70 (94)

[1]Age range in parentheses. [2]Percent agreement ± one year in parentheses.

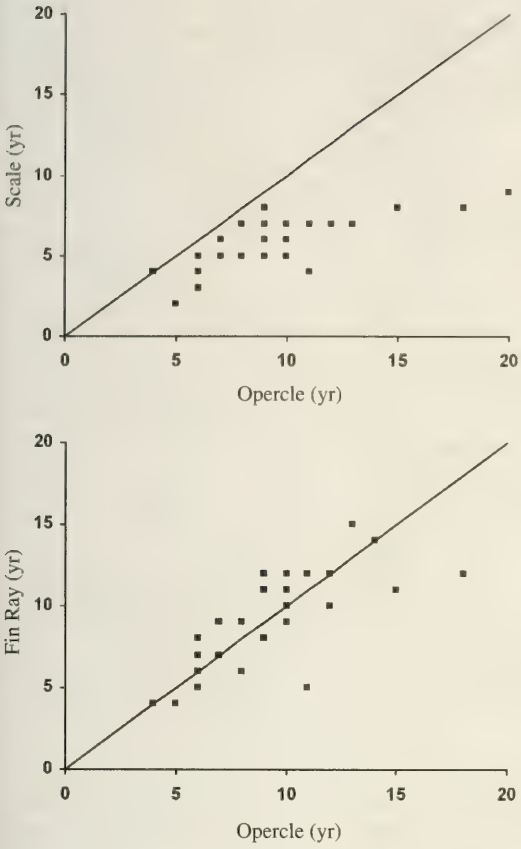

FIGURE 1. Comparison of Greater Redhorse opercle-based age estimates with those from scales (top) and pectoral fin rays (bottom). Opercle vs. scale CV (mean ± SE): 20.8 ± 2.3. Opercle vs. pectoral fin ray CV: 10.6 ± 3.6.

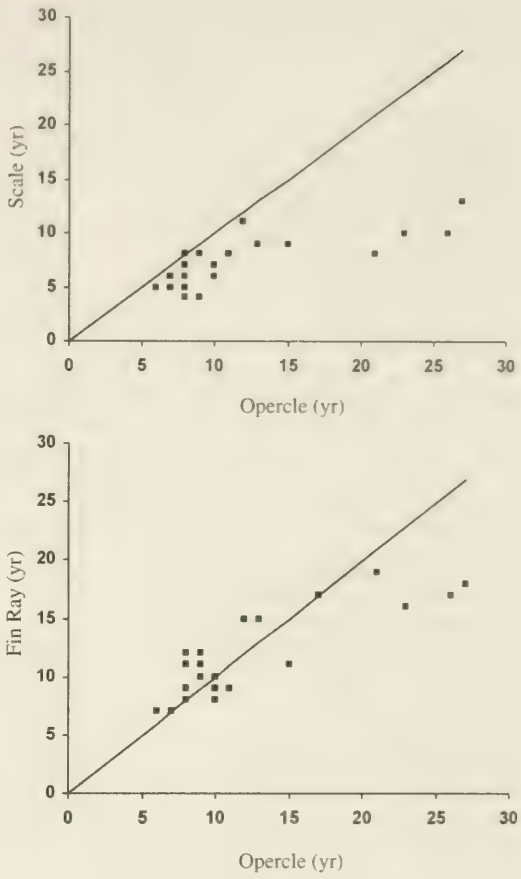

FIGURE 2. Comparison of River Redhorse opercle-based age estimates with those from scales (top) and pectoral fin rays (bottom). Opercle vs. scale CV (mean ± SE): 28.6 ± 5.8. Opercle vs. pectoral fin ray CV: 8.4 ± 1.4.

from the opercle (Figures 1 to 4). Mean pairwise differences between scale-based age estimates and those from fin rays and opercles were at least double that between fin rays and opercles (Table 2). Regenerated scales were common.

Agreement between age estimates from fin rays and opercles was greater than that between scales and the other two structures (Table 2). For all species except Silver Redhorse, there were no significant differences between age estimates from fin rays and opercles. However, the maximum difference between age estimates from these two structures was as large as 6 to 11 years. Fin ray based maximum age estimates were also 2 to 4 years less than those from opercles (Table 2). More frequent underestimation of age using fin rays began between ages 12 and 15 (Figures 1-4). For all species except Greater Redhorse, agreement between first and second interpretations of each structure was greater for pectoral fin rays and opercles than for scales (Table 2).

For Shorthead Redhorse and Silver Redhorse, sample numbers permitted an evaluation of whether differences in age estimates among structures were consistent across drainages. For Shorthead Redhorse, there was a greater level of agreement among Grand River structures (mean pairwise differences: 1.2 to 2.9 years) than among those from the Bay of Quinte (mean pairwise differences: 1.6 to 4.4 years) and Ottawa River (mean pairwise differences: 2.0 to 4.8 years) populations. The pattern reflects among drainage differences in the age of redhorse sampled, as Grand River Shorthead Redhorse were younger (mean age: 7.3) than those from Bay of Quinte (mean age: 9.2) and Ottawa River (mean age: 10.7). The level of agreement among structures from Silver Redhorse was equivalent for the similarly aged Bay of Quinte (mean pairwise differences: 2.4 to 5.9 years) and Ottawa River (mean pairwise differences: 2.4 to 6.5 years) Silver Redhorse populations. The mean age of both populations was 13 years.

TABLE 3. Comparison of maximum size (TL in cm) and maximum age for redhorse reported in past studies. For maximum age, superscript indicates structure used in the study: S:scale; F:fin ray: and O:opercle.

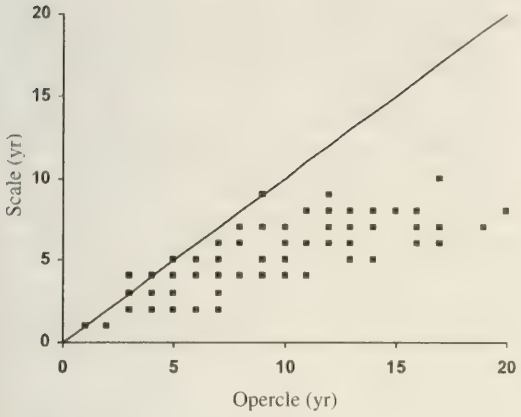
Discussion

This study indicates that pectoral fin rays are a more precise and accurate non-lethal age interpretation structure for redhorse than scales. However, underestimation of age can occur for fish older than 12 to 15 years. Observed overestimation of age at younger ages indicates the presence of false annuli or checks. Errors in the age interpretation of long-lived fishes can lead to substantial errors in estimates of growth, reproductive lifespan, age at maturity and survivorship. For northern redhorse populations where there is a larger representation of old individuals, pectoral fin ray based ages could overestimate growth and mortality rates and underestimate age at maturity. Determination of whether re-absorption of initial annuli occurs (Penha et al. 2004) would assist in further assessments of error associated with pectoral fin rays. If re-absorption is occurring in redhorse, age interpretations of older individuals could be improved by estimating the location of the first and second annuli using their average diameter calculated from juvenile fish, or those with clearly visible annuli (McFarlene and King 2001).

Maximum ages for Greater Redhorse (20 years), Shorthead Redhorse (20 years) and Silver Redhorse (27 years) are the oldest reported for these species (Table 3). The maximum for River Redhorse (27 years) was similar to that reported by Campbell (2001) for the Mississippi River, Ontario (28 years). The substantially higher maximum ages for Ontario populations could be the result of either the geographic differences among the populations compared or that most past studies have used scales to estimate age. Many of the redhorse species found in Ontario are near the northern limit of their range (Scott and Crossman 1979). For freshwater species with wide geographic distributions, northern populations tend to exhibit lower growth rates, later maturity and greater longevity than southern populations (Colby and Nepszy 1981; Mills 1988). For example, Huston (1999) reported the maximum age (interpreted from opercles) of more southerly River Redhorse populations in Missouri to be 15 years. Alternatively, the low maximum age of 5 years reported by Tatum and Hackney (1970) for river redhorse in the Cahaba River, Alabama, was likely an underestimation of age as a result of using scales (Jenkins and Burkhead 1993). For similarly sized (~60 cm TL) River Redhorse, scale-based age estimates from Huston (1999), Campbell (2001) and this study were up to 15 years less than



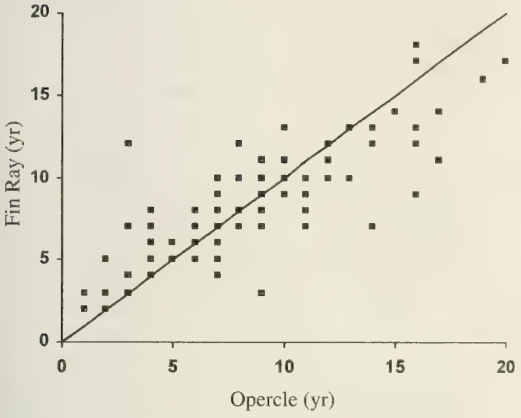


FIGURE 3. Comparison of Shorthead Redhorse opercle-based age estimates with those from scales (top) and pectoral fin rays (bottom). Opercle vs. scale CV (mean ± SE): 35.5 ± 2.8. Opercle vs. pectoral fin ray CV: 9.4 ± 1.0.

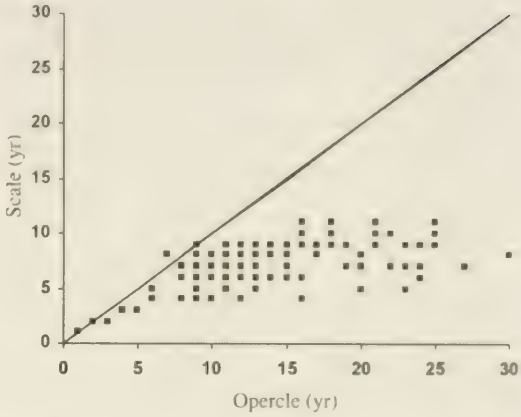

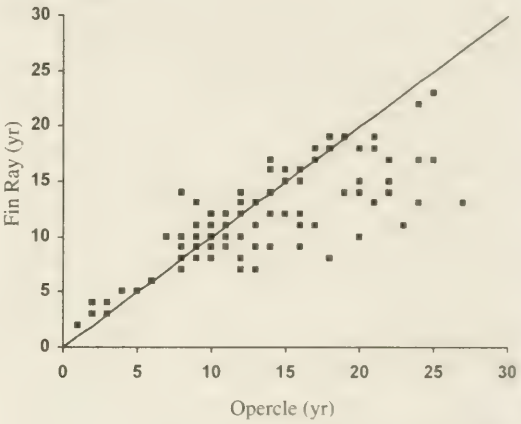

FIGURE 4. Comparison of Silver Redhorse opercle based age estimates with those from scales (top) and pectoral fin rays (bottom). Opercle vs. scale CV (mean ± SE): 31.8 ± 2.0. Opercle vs. pectoral fin ray CV: 25.3 ± 3.2.

opercle-based estimates. Underestimation of age resulting from the use of scales may also apply to maximum ages reported for Silver Redhorse in Alabama and Iowa (Meyer 1962; Hackney et al. 1970). For similarly sized Silver Redhorse in Ontario, scale-based age estimates were as much as 18 years lower than those from opercles.

Monitoring the status of imperiled redhorse species in Ontario will require non-lethal sampling methods. Results from this study indicate that pectoral fin rays are suitable for monitoring recruitment and detecting changes in population age structure. However, estimates of growth, mortality and maximum age are expected to be inaccurate. If more accurate estimates are necessary to meet monitoring objectives, opercles could be removed from a subset of the individuals sampled and used to: (1) back-calculate growth rates from measurements of annuli radii; and (2) adjust pectoral fin ray based age estimates of large (and presumably older) individuals.

Acknowledgments

The study was supported by the Ontario Ministry of Natural Resources and Industrial NSERC and Ontario Graduate scholarships awarded to S. Reid. Pectoral fin ray sections were prepared by Ontario Federation of Anglers and Hunters (Peterborough, Ontario). C. Robinson assisted with age interpretations. Some of the aging structures used in this study were provided by Fisheries and Oceans Canada. The manuscript was improved by comments provided by L. Carl, A. Dextrase, S. Stoklosar and two anonymous reviewers.

A Rare Case of Completely Ambicoloured Atlantic Halibut, *Hippoglossus hippoglossus*, from the Lower St. Lawrence Estuary, Quebec

Denis Chabot and Roberta Miller

Direction des sciences halieutiques et de l'aquaculture, Institut Maurice-Lamontagne, Pêches et Océans Canada, C.P. 1000, Mont-Joli, Québec G5H 3Z4 Canada

Chabot, Denis, and Roberta Miller. 2007. A rare case of completely ambicoloured Atlantic Halibut, *Hippoglossus hippoglossus*, from the lower St. Lawrence estuary, Quebec. Canadian Field-Naturalist 121(1): 35–39.

An Atlantic Halibut (*Hippoglossus hippoglossus*) (41.4 cm fork length) with the same pigmentation on the blind side as on the ocular side (ambicoloration) was captured in the lower St. Lawrence estuary, Canada, on 24 June 2004. This specimen represents the most extreme case of ambicoloration published for this species to date. As in other cases of extreme ambicoloration, this specimen shows other signs of abridged metamorphosis and reduced asymmetry, such as incomplete migration of the left eye and a hooked dorsal fin. Studies of hatchery-reared larvae have shown that the most common cause of malpigmentation, including ambicoloration, in halibut is a diet containing inadequate amounts and proportions of essential unsaturated fatty acids shortly before metamorphosis. Even though not expected to be common in the wild, inadequate diet for a short duration before metamorphosis is the most likely cause of ambicolouration in wild halibut.

Key words: Atlantic Halibut, *Hippoglossus hippoglossus*, ambicolouration; malpigmentation, metamorphosis, eye migration, hooked dorsal fin, St. Lawrence estuary, Quebec.

Flatfish larvae are normally pigmented on both sides, whereas juveniles and adults are usually pigmented only on their ocular side. Once metamorphosis begins, larval-type melanophores (pigment cells containing melanin) on the blind side go through cytolysis whereas developing adult melanophores differentiate on the ocular side (Norman 1934; Venizelos and Benetti 1999; Bolker and Hill 2000). However, some pleuronectiforms both wild and hatchery reared, have abnormal pigmentation patterns (Wheeler 1969; Gartner 1986; Bolker and Hill 2000). Malpigmentation ranges from deficiencies of pigmentation on the ocular side (hypomelanosis or pseudoalbinism) to an excess of pigmentation on the blind side (hypermelanosis or ambicoloration) (Venizelos and Benetti 1999; Bolker and Hill 2000).

Norman (1934) divided ambicolouration into three categories: staining, spotting and true ambicoloration. Staining is the development of irregular pigmented patches on the blind side that are lighter than the pigmentation of the eyed side and lack the characteristic spots and markings of the latter. Spotting is the presence of black or brown spots, in irregular or regular arrangement; the spots that are present occupy the same position as the characteristic dark spots found on the ocular side. Finally, true ambicoloration is when the coloring on the blind side is the same as that on the ocular side; true ambicoloration is often partial, involving the posterior part of the body while the head and a variable proportion of the anterior part remain white on the blind side. Very occasionally flatfish are completely ambicolored (Norman 1934).

Juvenile and adult Atlantic Halibut, *Hippoglossus hippoglossus*, are olive or slaty brown with some black on the ocular (right) side and strikingly white on the blind side, although the blind side can be of a more or less uniform grayish cast, or blotched with gray or even red, in older specimens (Gudger and Firth 1935; Scott and Scott 1988; Collette and Klein-MacPhee 2002). Here we describe a completely ambicoloured Atlantic Halibut and review the few past mentions of malpigmented Atlantic Halibut as well as studies dealing with possible causes of malpigmentation in general, and ambicolouration in particular.

Results

An Atlantic Halibut with a total length (TL) of 42.6 cm and a fork length (FL) of 41.4 cm was captured by bottom-trawling in the lower St Lawrence estuary, 48°56'N, 67°26'W on 24 June 2004 (depth = 90-100 m, temperature = 0.5-1.1°C). Nine normally-pigmented *H. hippoglossus* were captured during the 56 sets fished over 6 days in this area. No ambicolored Atlantic Halibut was captured during the annual survey of the northern Gulf of St. Lawrence and lower estuary for the years 1990-2005. This bottom-trawl survey was conducted by the Department of Fisheries and Oceans Canada in August and early September every year. A total of 310 normally-pigmented *H. hippoglossus* was captured in 3715 trawl sets during this period.

The blind side of the ambicoloured fish was exactly the same colour as the ocular side, except for a lack of pigmentation on the distal half of the pectoral fin and one small white spot (1-2 mm) in the middle of the left side. The anterior end of its dorsal fin had grown into a hook detached from the head. Furthermore, the left eye had not completed its migration to the right side and remained partly visible from the blind side. Photos of the ocular and blind sides of this fish are shown in Figure 1. For comparison, a normal Atlantic Halibut

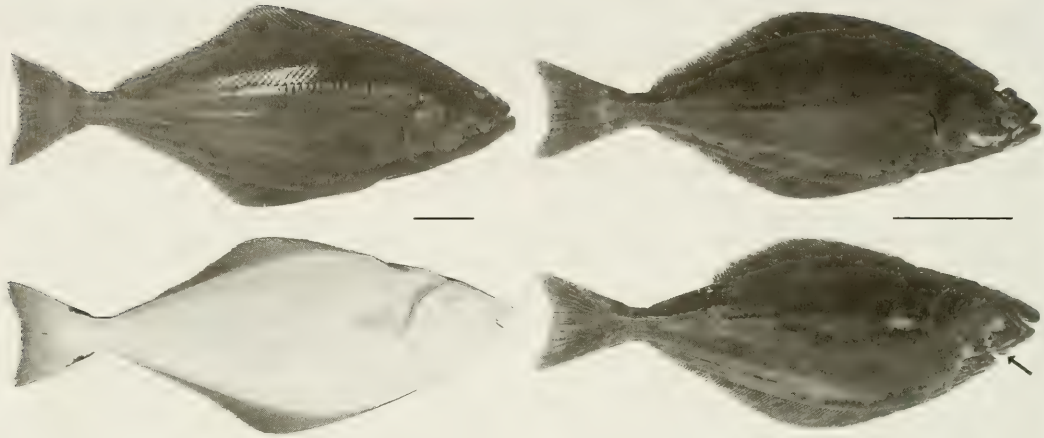

FIGURE 1. Ocular (top) and blind side (bottom) of a normal (left) and ambicoloured (right) Atlantic Halibut, *Hipoglossus hippoglossus*. A 10-cm scale bar is shown next to each fish. The left eye of the ambicoloured fish has not completed its migration and is partly visible from the blind side (arrow). Pale areas on the blind side of the head of ambicoloured fish are caused by light reflection: pigmentation was the same as on the ocular side.

(85.9 cm TL and 84.7 cm FL [Fork Length]) captured at about the same location on 25 June 2004 (depth = 120-130 m, temperature = 1.8-2.0°C) is also shown.

Discussion

An almost completely ambicoloured Atlantic Halibut was described by Gudger and Firth (1935). Like the present specimen, it had a hooked dorsal fin and incompletely rotated left eye. Unlike the present specimen, about 30% of the blind side of the head was white, and except for the distal half of the pectoral and caudal fins, the remainder of the blind side was darker in colour than the ocular side, almost black. Gudger and Firth (1937) mention two other *H. hippoglossus* that were partially ambicoloured and reversed (the eyes were on the left side). A literature search revealed no further occurrences of wild ambicoloured halibut. However, malpigmentation is common in hatchery-reared Atlantic halibut and ambicoloration is often accompanied by a hooked dorsal fin and incomplete eye migration (Næss et al. 1995; Pittman et al. 1998).

Bolker and Hill (2000) discussed two possible explanations for malpigmentation. The first hypothesis asserts that the development of the normal pigmentation asymmetry in flatfish is associated with the development of a fundamental left-right distinction. The lack of development of adult melanophores on the blind side is not due to the lack of precursor cells, but rather to a difference in the histological structure of the skin on both sides of the fish (Seikai and Matsumoto 1994). Failure of this differentiation to develop can prevent adult melanophore development on the ocular side and result in pseudoalbinism. Although not as thoroughly studied, ambicoloration could also be explained in this manner. The second hypothesis to explain malpigmentation, or at least pseudoalbinism, involves dietery-based abnormal development of the retina. The resulting visual defects are thought to lead to a failure of a hormonal signal necessary for melanophore development on the ocular side. Bolker and Hill (2000) noted that the two hypotheses were not mutually exclusive.

Incomplete eye migration could be the cause of ambicoloration if optical signals were still interpreted by the brain as coming from the blind side, resulting in ocular-side melanophore development on the blind side. However, this hypothesis is not supported by the results of studies of hatchery reared Atlantic Halibut, where ambicoloration was found in fish that had complete eye migration (e.g., Hamre et al. 2002), and conversely, both normally coloured and ambicoloured Atlantic Halibut exhibited a lack of eye migration (Pittman et al. 1998).

In wild fish, partial ambicoloration is usually not associated with other abnormalities, whereas Norman (1934) and Gudger and Firth (1936) noticed that in almost completely ambicoloured flatfish with pigmentation on at least 25-35% of the blind side of the head, eye migration was usually incomplete and the anterior end of the dorsal fin was hooked. Incomplete eye migration and the presence of a hooked dorsal fin are expected to occur together: pterygiophores (bones supporting the dorsal fin) normally expand towards the snout during metamorphosis, after the left eye clears the dorsal crest (Norman 1934; Gudger and Firth 1935; Brewster 1987). Incomplete eye migration, where the left eye does not clear the dorsal crest, prevents normal pterygiophore expansion. Furthermore incomplete eye migration is accompanied by incomplete torsion of the neurocranium, resulting in the formation of a hooked dorsal fin (Sæle et al. 2004). Total or nearly

total ambicoloration is also accompanied by other abnormalities such as pectoral fins that are more equal in length than in normally pigmented fish, and the presence of the same type of scales on the coloured areas of the blind side as those on the ocular side.

As pointed out by Norman (1934), the anterior part of the head is coloured only in the most complete cases of ambicoloration and is also the most asymmetrical part of a flatfish. Thus the available observations indicate that the gradient in ambicoloration corresponds to a gradient in the level of perturbation during metamorphosis. Pigmentation of a small proportion of the blind side is a minor developmental defect, whereas complete ambicoloration is a sign of more profound disturbances resulting in a less complete metamorphosis, i.e., a reduction of asymmetry including incomplete eye migration and almost complete pigmentation of the blind side. However, the causes of these developmental defects are not well understood, especially for wild fish.

Many possible causes of malpigmentation have been proposed that involve flatfish larvae before or during metamorphosis, including diet, water quality, stocking density, extreme temperature, UV light, stress and genetic factors (for reviews see Gartner 1986; Seikai and Matsumoto 1994; Venizelos and Benetti 1999; Bolker and Hill 2000; Hamre et al. 2005). Inadequate diet is now thought to be the most important cause of malpigmentation. Pseudo albinism was a very common problem when hatcheries started to grow halibut larvae and fed them artemia. This was alleviated when larvae were fed a natural copepod-based diet during a specific premetamorphic stage that constitutes a critical period (Næss et al. 1995; Næss and Lie 1998; Shields et al. 1999). In particular, levels and proportions of essential unsaturated fatty acids are important for successful pigmentation. Artemia are low (in proportion of total lipids) in docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) and high in arachidonic acid (ARA) compared with copepods (Næss et al. 1995; Copeman et al. 2002; Hamre et al. 2005). High levels of DHA resulting in a DHA/EPA ratio > 1, reduced levels of ARA and high EPA/ARA ratios decrease the incidence of pseudoalbinism, incomplete eye migration and hooked dorsal fin (Næss et al. 1995; McEvoy et al. 1998a; Næss and Lie 1998; Shields et al. 1999; Hamre et al. 2002). Other nutritional differences between artemia and copepods may contribute to pigmentation, such as the greater proportion of polar lipids (McEvoy et al. 1998b), vitamin A (or its precursors, carotenoid compounds) and iodine (Hamre et al. 2005) in copepods.

Less attention has been paid to the development of ambicoloration. It can be voluntarily produced in the Japanese Flounder, *Paralichthys olivaceus,* by immersing larvae in water containing retinoic acid (Haga et al. 2005). Ambicoloration is an undesirable trait in hatcheries that is not normally induced voluntarily, but rather occurs spontaneously at incidence rates that depend on diet. Most diets that reduce the incidence of pseudoalbinism also increase the incidence of hyper melanosis of the blind side (for a review, see Haga et al 2004). For instance, an excess of vitamin D_3 (Hasegawa et al. 1998; Haga et al. 2004) or A (Miwa and Yamano 1999) can increase the rate of ambicoloration in the Japanese Flounder. In Atlantic Halibut, copepod-based diets sometimes resulted in ambicoloration for up to 30-40% of the fish (Shields et al. 1999; Hamre et al. 2002; Hamre et al. 2005), but in other studies it did not (Næss et al. 1995; Næss and Lie 1998). This is likely the result of variability in nutritional properties of the copepods used, as the quantities and ratios of unsaturated fatty acids, vitamins and other nutrients changed between batches or size-classes of copepods within and between studies (e.g., Næss et al. 1995; McEvoy et al. 1998a; Shields et al. 1999; Hamre et al. 2002). Diet-induced ambicoloration is conceivable in wild halibut as well: hatching time, egg condition and environmental conditions all influence when larvae begin to metamorphose and the availability and quality of prey items. Laboratory studies have shown that the critical period during which diet influences the development of post-metamorphic pigmentation is short, making it possible for wild fish to have a suboptimal diet near the beginning of metamorphosis and become ambicoloured.

Malpigmentation can also occur in post-metamorphic flatfish. Many wild fingerlings of Speckled Flounder (*Paralichthys woolmani*) that were normally pigmented when captured developed white spots on their ocular side within a few days. Most of them returned to a normal pigmentation within one year, except for a few that retained some pigmentation on their blind side (Benetti 1997; Venizelos and Benetti 1999). Light reaching the blind side where it is not in contact with the bottom, and lack of sediment in which fish can bury themselves can also result in some pigmentation on the blind side of flatfish (Cunningham 1893; Ottesen and Strand 1996). However these are examples of staining, not ambicoloration. True ambicoloration appears to be in place soon after metamorphosis.

It is difficult to assess whether factors leading to malpigmentation in hatchery-reared halibut would do so in the wild, or if these factors are even relevant in the wild. Halibut larvae likely encounter appropriate prey items in the wild. However, considering the high incidence of malpigmentation when diet is inappropriate for only a few days in hatcheries, and the fact that non-diet related causes of malpigmentation in captive Atlantic Halibut (light, sediment type, stocking density, etc.) are even less likely to be problematic in the wild, diet is the most likely of the known causes of malpigmentation to occur in the wild. Other possible causes, such as a genetic causes, remain possible, however. True albinism (i.e., presence of red eyes) is inheritable in the Japanese Flounder (Shikano 2005), but diet appears much more important than genetic factors in the development of pseudo-albinism and ambicolouration (Seikai and Matsumoto 1994).

Few wild ambicoloured Atlantic Halibut have been reported, but reporting rate is unknown. Reporting malpigmentation should be encouraged in scientific surveys for this species as well as others to assess incidence and mortality rate of ambicoloured fish and improve our understanding of the causes of ambicolouration in Atlantic Halibut, and of taxonomically related incidence rates in flatfish (e.g., Díaz de Astarloa et al. 2006).

The specimen presented in this study has been preserved and is part of the Maurice-Lamontagne Institute Collection (accession number 11633).

Acknowledgments

We thank G. Hogan and V. Puvanendran for their helpful comments on an earlier version of the manuscript.

Frey, Brenda, Chaim Kempler, and David L. Ehret. 2007. Micro-propagation of White-top Aster, *Sericocarpus rigidus*, a threatened species from the Garry Oak Ecosystem in British Columbia. Canadian Field-Naturalist 121(1): 40–45.

A study was undertaken to examine the feasibility of using micro-propagation techniques to regenerate White-top Aster (*Sericocarpus rigidus*), a threatened species native to the Garry Oak ecosystem in coastal British Columbia. Shoot multiplication from explants was compared in three different basal media formulations. The effects of varying IAA (indole-3-acetic acid) and kinetin on shoot production were also investigated using one of the three basal media. Shoot production was most successful on modified MS (Murashige and Skoog) media containing various concentrations of BAP (benzylaminopurine) and GA_3 (gibberellic acid), followed by media containing IAA and kinetin at concentrations of 2 mg l^{-1}. Root formation occurred readily on modified MS media with IAA and reduced macronutrient and micronutrient concentrations. The study showed that *S. rigidus* can be successfully propagated using *in vitro* shoot multiplication.

Key Words: *Sericocarpus rigidus*, *Aster curtus*, White-top Aster, micro-propagation, Garry Oak ecosystem, British Columbia.

The Garry Oak ecosystem has a geographic distribution that spans the west coast of North America, from southwestern British Columbia to southern California. In recent years, the survival of this ecosystem in Canada has been threatened by fire suppression and by residential, industrial and agricultural development. These activities have resulted in loss of species habitat, habitat degradation and the spread of invasive exotic species (Garry Oak Ecosystem Recovery Team 2002*). The Garry Oak ecosystem contains more plant species than any other terrestrial ecosystem in coastal British Columbia, and many plants that live in the ecosystem do not occur elsewhere in Canada. It is now estimated that less than 5% of all Garry Oak sites remain in their natural state (Garry Oak Ecosystem Recovery Team 2002*).

The White-top Aster, *Sericocarpus rigidus* (formerly *Aster curtus*), is an herbaceous perennial species of Asteraceae native to low elevation grasslands in the Pacific Northwest in the United States and the associated Garry Oak ecosystem on Vancouver Island, British Columbia (Clampitt 1987). Due to the serious loss of habitat, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) designated White-top Aster as a threatened species in 1996, and the species is now protected under the Species At Risk Act (SARA) (Environment Canada 2006*). *Sericocarpus rigidus* produces underground rhizomes, and as a result, occurs in patches which can vary tremendously in size. Shoots emerge from rhizomes in April, flower in July and August, then die back in the autumn. Seedlings are rarely, if ever, observed, making rhizomes the major form of propagation (Douglas and Illingworth 1997). Even though *S. rigidus* produces an abundance of seeds, viability is low and often uneven. In pollination studies, Clampitt (1987) found that excluding pollinators by bagging ramets significantly reduced the percentage of viable seeds (measured with tetrazolium chloride) from 20% in the unbagged treatment to 5% in the bagged. Bigger (1999) found that exposed and hand-pollinated flowers generally had the same number of viable seed (as tested with tetrazolium chloride), but differences in seed viability between hand-pollinated and exposed plants varied greatly among sites, possibly due to pollinator limitations in some patches. Patch size was also found to influence the degree of predation by insects. Overall, seed viability varied from 0 to 83%. In a field comparison of open pollinated, between patch pollinated, within patch pollinated and pollination excluded treatments, Giblin (1997) found that open and between patch pollination treatments produced significantly more filled seed (39% and 35%, respectively) than within patch and pollination exclusion treatments (18% and 9%, respectively). In terms of conditions required for germination, Clampitt (1987) showed that stratification and exposure to light increased germination. Ehret et al. (2004) have shown that the seeds required an 8–12 week period of stratification for germination and seedlings are slow to establish. Even so, Giblin and Hamilton (1999) suggest that the reproductive biology of the species does not contribute to its rarity.

Sericocarpus rigidus was one of three species "at risk" plants studied at the Pacific Agri-Food Research Centre (PARC) with the objective of developing propagation methods that would allow for the generation of plant material that could be reintroduced into protected Garry Oak ecosystems, parks and ecological

reserves or made available to native plant nurseries. Because of the difficulties associated with seed germination, micro-propagation was studied with the objective of developing a method that could rapidly and reliably produce plantlets.

Materials and Methods

Plant Material

Seeds were collected from two patches of *S. rigidus* growing at an elevation of 220 m on Mt. Tzuhalem (48°47'N, 123°38'W) on Vancouver Island in September 2001 and from another patch at the same location in September 2002. The collection sites were 100 to 300 m apart. Given the close proximity, all plants may have been derived from the same clone. Collected seed count varied from 50 to 200 per plant. Seeds from 2001 were dried and stored at room temperature in the dark for one year. In September 2002, all seeds were placed in the dark in a cooler at 4°C. In October 2002, 15 to 30 seeds from each patch were placed on damp filter paper in petri dishes and incubated in a growth chamber maintained at 20°C and 14/10 h light/dark. After three weeks, only four seeds had germinated and all were collected from the same patch in 2001. These were potted in 10 cm pots containing Sunshine Mix 4, (Sun Gro Horticulture Inc., Vancouver, British Columbia) and were over-wintered in a greenhouse. In May 2003 the seedlings were hardened off in a cold frame for four weeks before being transplanted into a silt loam soil in irrigated raised beds at PARC. After one season of growth and flowering, seeds were collected from those plants in October 2003, and after air drying, were stored in a cooler at 4°C for 3 months. Surface sterilization of 10 seeds was conducted by suspending the seeds in a 5% solution of PPM (Plant Preservative Mixture) (Plant Cell Technology Inc., Washington D.C., USA) and deionized water (v/v) in a beaker on a shaker for 24 h. Seeds were aseptically transferred to a petri dish containing a 1.5% solution of sterile Bacto agar in deionized water (w/v). The petri dish was sealed with parafilm and placed in a plastic bag in a refrigerator at 3°C in the dark.

After nine weeks at 3°C, one seed germinated. This was the only seed that germinated during the next five months. The seedling was removed from the petri dish under sterile conditions and placed in a 350 ml jar containing half-strength MS (Murashige and Skoog 1962) media containing 1.0 mg L^{-1} IAA and 0.1 mg L^{-1} kinetin. The jar was placed in a growth room maintained at 22–25°C with a 16/8 h light/dark cycle using fluorescent light with a PPFD (photosynthetic photon flux density) of ~50 µE m^{-2} s^{-1}. After five weeks, the fully developed, healthy seedling was transferred to a modified MS medium containing half the concentration of ammonium nitrate (825 mg•L), 2.0 mg•L^{-1} IAA and 2.0 mg l^{-1} kinetin. After four weeks on this medium, shoot and roots were excised and cultured on fresh media. Cultures were maintained by bimonthly transfer to fresh media until enough shoots were generated to conduct shoot multiplication and rooting experiments. The excised root tissue failed to grow after being removed from the shoot and was discarded.

Shoot Induction

A replicated shoot multiplication experiment was initiated to determine the effects of various concentrations of IAA plus kinetin or BAP plus GA_3 on the growth of explant shoots produced on modified MS media. The experimental design was a randomized complete block design consisting of seven media treatments with six replicate jars, each containing five explants. The experiment included three modified MS basal medium (BM) formulations with each formulation containing a different concentration of macronutrients, micronutrients and organic additives (Table 1). BM1 was a formulation used in earlier micropropagation media development using the cultivated violet species, *Viola praemorsa* (Ehret et al. 2004). BM2 and BM3 were modified MS media used routinely in the PARC strawberry and raspberry breeding programs for shoot proliferation. The ammonium nitrate concentration of BM1 was half that of the other media because higher rates of ammonium nitrate have been found to be toxic to cultures of some plant species because the uptake of ammonium ions can acidify the medium and increase the frequency of vitrification (Slater et al. 2003). BM1 was the basal media used in media treatments 1 through 5 and it was supplemented with five combinations of IAA and kinetin as follows: 0.5 mg•L^{-1} IAA + 1.0 mg•L^{-1} kinetin (M1), 0.5 mg•L^{-1} IAA + 2.0 mg•L^{-1} kinetin (M2), 2.0 mg•L^{-1} IAA + 1.0 mg•L^{-1} kinetin (M3), 2.0 mg•L^{-1} IAA + 2.0 mg•L^{-1} kinetin (M4) and 3.0 mg•L^{-1} IAA +2.0 mg l^{-1} kinetin (M5). M4 was the initial shoot multiplication media used to generate plant material for the experiment. BM2 was the basal media used in treatment 6 (M6) and it was supplemented with 2.5 mg•L^{1} BAP and 0.01 mg•L^{-1} GA_3. BM3 was the media used in treatment 7 (M7) and it was supplemented with 1.0 mg•L^{-1} BAP and 0.01 mg•L^{-1} GA_3. The ferrous sulphate and Fe-EDTA supplied in BM1 and BM2 was replaced by Sequestrene 138 (Becker Underwood Inc., Ames, Iowa, USA) in BM3.

The pH of all media treatments was adjusted to 5.6–5.7 and the media were then dispensed into 350 mL jars which were covered with cellophane and autoclaved. Explants which had a mean weight of 0.164 g ± 0.008 (SE), were aseptically transferred into treatment jars which were incubated in a growth room maintained at 22–25°C with a 16/8 h light/dark cycle using fluorescent light with a PPFD of ~50 µE m^{-2} s^{-1} for four weeks. After four weeks, the number of explants that produced shoots and roots, the number of shoots produced per explant, and shoot and explant fresh weights were recorded.

Root Induction

A separate rooting experiment was conducted using BM4 (Table 1) which is used in the PARC berry breed-

TABLE 1. Four modified Murashige and Skoog (MS) basal media (BM) formulations used for *S. rigidus* culture. Rates are expressed in mg•l^{-1} with the exception of Plant Preservation Mixture, which is expressed in ml l^{-1}.

	Induction Media			
	Shoot			Root
	BM1	BM2	BM3	BM4
Macronutrients				
Ammonium nitrate	825	1650	1237	464
Calcium chloride (anhydrous)	332	332	332	332
Magnesium sulphate ($MgSO_4 \cdot 7H_2O$)	370	370	370	370

ing program for root development. Fifteen shoot samples initiated on M4 were placed on the rooting medium containing 1.0 mg•L^{-1} IAA. After four weeks, rooted plants were transferred to Sunshine Mix 4 potting mix and moved to a greenhouse where they were acclimatized.

Statistical Analysis

Data were analysed using the general linear model procedure in SAS (SAS Institute, Cary, North Carolina, USA), for one-way analysis of variance (ANOVA). All independent factors were fixed. Where ANOVA results were significant, treatment means were separated by Duncan's multiple range tests. Data expressed in percentages were transformed by arcsin transformations before statistical analysis.

Results and Discussion

In general, explants grew rapidly in culture, with extensive shoot multiplication (Figure 1 a, b). After four weeks of culture, explant survival ranged from 83.3 to 100 percent with no significant survival differences among media treatments (Table 2). The percentage of surviving explants that produced shoots ranged from 61 to 100%. Just over 60% of M1 and M3 explants produced shoots compared to 90–100% of explants cultured on M4–M7. In addition, explants cultured on M1, M2 or M3 produced roots while being cultured on shoot multiplication media (data not presented). M1 and M3 which had the lowest concentrations of kinetin produced the greatest number of roots, 13 and 20 % respectively. These results suggest that aster media should contain kinetin at minimal rates of 2.0 mg•L^{-1} to avoid root initiation during the shoot multiplication stage. This supports previous recommendations that kinetin be added to a medium for cell division, shoot multiplication and axillary bud proliferation while IAA should be added to promote cell enlargement, root initiation and adventitious bud formation (Kyte and Klein 1999).

Mean explant plus shoot weights ranged from 0.241 to 0.855 grams. No statistically significant differences were observed among BM1 treatments. M6 produced a significantly greater biomass than all other media, followed by M7 which had a significantly greater biomass than M1 to M3 (Table 2, Figure 1c). Explants and shoots cultured on M6 appeared slightly chlorotic compared to those cultured on M7 which were the darkest green of all treatments (data not presented). Explants cultured on M2 and M3 were the least vigorous; explant and shoot leaves appeared mottled and there

Four-month-old rooted aster plants in the greenhouse.

were several dead leaves at the base of the explants.

The number of shoots per surviving explant ranged from 1.72 to 6.19 shoots per explant (Table 2). Within the BM1 treatments, M2 and M3 produced significantly fewer shoots than M4. Treatments M6 and M7, both of which contained BAP and GA_3 and which were on BM2 and BM3, respectively, produced a greater number of shoots per explant than most BM1 treatments containing combinations of IAA and kinetin.

The mean weight of individual shoots cultured on the different media ranged from 0.037 to 0.097 grams per shoot. Few consistent differences were observed among the five BM1 treatments. Compared to those treatments, M6 (on BM2 with BAP and GA_3) produced shoots with the greatest weight. Despite some differences among BM1 treatments, the results show

that the ratio and the concentration of IAA and kinetin in BM1 did not have a consistent effect on overall shoot multiplication. Shoots were small and difficult to handle after four weeks of culture. Extending the culture time from four to five weeks would likely have increased shoots to a size that would have made them easier to transfer and a more desirable size for rooting.

Root initiation was 100% on the BM4 medium (data not shown). Roots appeared on the shoots after 7 days of culture, and after 4 weeks a healthy root system had fully developed. The rooted plants were easily acclimatized to a greenhouse environment and showed vigorous growth (Figure 1d). Other methods to induce root development were not attempted since this technique was so highly successful.

Micro-propagation methods for commercially important species of Asteraceae such as sunflower (*Helianthus annuus*) employ a variety of techniques to regenerate plants (Alibert et al. 1994). There are also methods to micro-propagate other Asteraceae species of commercial value, such as feverfew (*Tanacetum parthenium*) (Simmons 1998), marigold (*Tagetes erecta*) (Vanegas et al. 2002), *Echinacea pallida* (Koroch et al. 2003) and safflower (*Carthamus tinctorius*) (Orlikowska and Dyer 1993). These techniques have increasingly been used on medicinally important Asteraceae species such as goldenrod (*Solidago virgaurea, S. canadensis, S. gigantea* and *S. graminifolia*) (Kelemba and Thiem 2004) and those which are rare, such as *Saussurea obvallata* (Joshi and Dhar 2003). In Canada, micro-propagation of the Gulf of St. Lawrence Aster, a rare species in Prince Edward Island, has been shown to have potential in conservation efforts (Stewart and Lacroix 2001).

Meristem culture has been extensively used for the clonal propagation of horticultural plants. Since the constituent cells of meristems are genetically stable, plants regenerated by *in vitro* culture of shoot apices without the callus-mediated process of organogenesis should result in the recovery of genetically identical progeny. Because the culture was started from a single seed and mass regenerated in tissue culture, genetic variability is limited. *Sericocarpus rigidus* propagates clonally in the wild by underground rhizomes, so *in vitro* mass clonal propagation could be a good strategy for preservation and reintroduction of this threatened species.

Our study is the first to show that the threatened Asteraceae species, *S. rigidus*, can also be successfully propagated using micro-propagation techniques. Only one germinated seed was available for use in the study. However, by its very nature, micro-propagation works at the level of single seeds or explants, so our situation is not atypical. The genetic variability of the Mt. Tzuhalem population of *S. rigidus* is not known, but since the plant occurs in clonal patches, it is unlikely that other seeds of *S. rigidus* would respond differently to micro-propagation. The best results for shoot mul-

tiplication were obtained with combinations of BAP and GA_3, a regime which has not often been used in other Asteraceae studies. Further work is required to determine the optimum basal medium formulation to use with the most successful combinations of BAP plus GA_3 in order to generate the greatest number of vigorous *S. rigidus* shoots. Additionally, research with vegetative tissue as a source of explants, rather than seeds, could be conducted in order to avoid the time and difficulties associated with seed germination. However, from a conservation point of view, harvesting vegetative tissue, particularly rhizomes, from a threatened or endangered species may be less desirable than harvesting seeds because of damage to the plant and disturbance of the site.

The costs of micro-propagation were not evaluated against more conventional propagation techniques. Tissue culture is cost effective and is used commercially in the propagation of many plants. Although it requires more knowledge and extra capital to start a micropropagation operation, the rate of propagation is much faster than in conventional propagation. Given that hundreds of propagules of an endangered or threatened species may be generated using micro-propagation, the effort seems reasonable.

Acknowledgments

The authors thank Georgia Kliever and Frederic Bounaix for technical assistance, and Matt Fairbarns for collecting seed and providing advice. This study was partially funded by the Interdepartmental Recovery Fund of Environment Canada.

Shaffer, Jill A., Gregory A. Knutsen, Ron E. Martin, and Joel S. Brice. 2007. Pattern and potential causes of White-faced Ibis, *Plegadis chihi*, establishment in the northern prairie and parkland region of North America. Canadian Field-Naturalist 121(1): 46–57.

The Northern Prairie and Parkland Waterbird Conservation Plan calls for renewed attention to determining the current status of waterbird populations, their distributions, and conservation needs. It highlights the need for baseline information on the White-faced Ibis (*Plegadis chihi*). In response, we examined the historical and current distribution of the ibis in North Dakota and summarized first sightings and nest records for the provinces and other states composing the northern prairie and parkland region. The establishment of breeding colonies of White-faced Ibis here may be due to climate and precipitation patterns, invasion and spread of Narrowleaf Cattail (*Typha angustifolia*), changes in agricultural practices, habitat loss and range expansion in the southern and western portions of the species' range, and increases in ibis populations in the Intermountain West. We placed special emphasis on North Dakota, a state for which there is scant published information concerning the current status of this species. In recent decades, the ibis has become a regular breeding-season resident in North Dakota and in other areas of the northern prairie and parkland region. From 1882 to 2002, there were 145 reports of one or more White-faced Ibis in North Dakota, including 93 reports during the breeding season (15 May to 31 August), 49 during the non-breeding season (1 September to 14 May), and three for which the season of occurrence was not reported. Prior to the 1960s, there were only three records of the species in North Dakota. Observations of White-faced Ibises in North Dakota increased dramatically between the 1960s and the early 21st century, and the species has been observed nearly annually since 1971. The first White-faced Ibis nesting activity in the state was recorded in 1978, and to date, there have been 21 known records of nesting activity in the state. The species nested in large (>300 ha) semipermanent or permanent wetlands within mixed-species colonies ranging in areal extent from small (0.1 ha) to fairly large (27 ha), and colonies were located in patches of emergent vegetation dominated by cattails (*Typha*) and bulrushes (*Scirpus*). We classify the White-faced Ibis as a fairly common migrant and a locally uncommon breeder east of the Missouri River and a casual migrant west of the Missouri River.

Key Words: White-faced Ibis, *Plegadis chihi*, colonial-nesting waterbird, distribution, status, northern prairie and parkland region, North Dakota.

The White-faced Ibis (*Plegadis chihi*; hereafter ibis) is a wading bird that nests in wetlands with emergent vegetation and forages in shallow wetlands, flooded hay meadows, or agricultural fields (Ryder and Manry 1994). Northernmost populations undertake regular north-south migrations, whereas populations in Texas and Louisiana are mainly year-round residents (Ryder and Manry 1994). Extralimital wanderings seem to be more prevalent before the nesting season than afterward and may represent individuals seeking new nesting areas when traditional sites are dry or have been destroyed by humans (Ryder 1967; Ryder and Manry 1994). During the twentieth century, numerous sightings of the species east and north of its historical range were reported (Sabo 1992; Jorgenson and Dinsmore 2005).

The recently completed North American Waterbird Conservation Plan (Kushlan et al. 2002) and its regional offshoot, the Northern Prairie and Parkland Waterbird Conservation Plan (NPPWCP) (Beyersbergen et al. 2004), called for renewed attention to determining the current status of waterbird populations, their distributions, and conservation needs. The NPPWCP emphasized that information on the breeding distribution of ibis in the northern prairie and parkland region (portions of Alberta, Saskatchewan, Manitoba, Montana, North Dakota, South Dakota, Minnesota, Iowa, and Nebraska) is needed to serve as a baseline for future monitoring needs (Beyersbergen et al. 2004). In response to these information needs, we examined the historical and current distribution of the ibis in North Dakota and summarized first sightings and nesting records for the provinces and states composing the northern prairie and parkland region. We placed special emphasis on North Dakota, a state for which there is scant published information concerning the current status of this species.

Lokemoen (1979) and Schmidt (1980a) summarized the first occurrences and nest records of White-faced

Ibis in North Dakota. Sabo (1992) described the status, range, first occurrences, and first nesting observations for some Great Plains states and Canadian provinces. Goossen et al. (1995) provided a detailed list of observations and breeding records for the species throughout Canada. Jorgenson and Dinsmore (2005) provided an update of breeding records throughout the Great Plains. In this paper, we summarize the reported occurrences of White-faced Ibis in North Dakota up to 2002, and we report nest records through 2003, beyond which time the U.S. Fish and Wildlife Service (USFWS) no longer quantified colony and nest numbers. We discuss factors influencing the species' expansion into the state and provide data on the species' breeding habitat. We also explain how the pattern of occurrence of the species in North Dakota compares to the general pattern throughout the rest of the northern prairie and parkland region.

Methods

Records of ibis occurrences in North Dakota were summarized from published reports, including those in *American Birds*, *Audubon Field Notes*, *National Audubon Society Field Notes*, and *North American Birds*, and unpublished reports filed with the North Dakota Birding Society (REM, unpublished data). We included data from the North American Breeding Bird Survey (BBS; 1966-2002; Sauer et al. 2005*), the National Audubon Society's Christmas Bird Count (NAS 2007*), and banding records from the U.S. Geological Survey Bird Banding Laboratory (USGS 2007*).

We defined a record as a museum specimen or a reported occurrence of an individual, group of individuals, or a colony. Records were summarized by date (year, month, and day if known) and location (to county level at a minimum). Nest records were defined as the presence of nests, eggs, dependent young, or adults exhibiting breeding behavior (e.g., carrying nesting material). Observations from 15 May to 31 August were considered breeding-season records, and observations from 1 September to 14 May were considered nonbreeding-season records, based on authors' observations of ibis behavior and phenological information as described by Ryder and Manry (1994). Occurrences of ibises at the same location over a range of days to months were counted as a single observation for purposes of annual summaries. To summarize data for the breeding and nonbreeding seasons, reports of the species at the same location within both seasons were counted as separate records, unless information indicated that individuals had nested at the location and were still present during the nonbreeding season.

We summarized information on use of wetlands for nesting from one published nest record and from three studies that measured habitat attributes of nesting ibis in North Dakota. Schmidt (1980a) provided a brief description of the habitat attributes of a wetland that supported several flightless young in 1978 and of one nest in southern North Dakota in 1979. During June and July 2000, Brice (2003) documented a multi-species colony that included ibis nests at Lake Alice National Wildlife Refuge (NWR; 48°19'54"N, 99°06'38"W), western Ramsey County, in northeastern North Dakota. Colony size was defined as the area occupied by nests of all colonially nesting species within the colony boundary, not just by ibis nests. Within the colony boundary, number of ibis nests, dominant vegetation, and presence of other bird species nesting within the colony were recorded. Two transects were placed lengthwise through the colony. The percent of water surface that was not covered or obstructed by standing or horizontal residual vegetation (i.e., percent open water), residual stem density, and water depth were measured within 86 1-m^2 sampling frames placed at 10-m intervals along the two transects (Table 1). Percent open water within the colony was recorded by visual estimation. Water depth was recorded using an approximately 3-cm diameter closet rod marked in 1-dm intervals. In 2001, this same colony was monitored for the presence of breeding ibises by USFWS personnel (Phelps and Meeks 2001*). Percentages of colony area composed of residual emergent vegetation and open water were visually estimated. During June and July 2001 and 2002, the USFWS (2001*, 2002*) documented ibis nesting activity on USFWS lands in Burleigh, Emmons, and Kidder counties in south-central North Dakota. The number of nests, the number of colonies, the dominant vegetation within colonies, and the presence of other nesting bird species were recorded on one NWR and one waterfowl production area (WPA). The ratio of live-to-residual emergent vegetation within colonies was visually estimated. In 2001, water depth at nests was measured using a meter stick. During June 2003, Knutsen (2004*) conducted a colonial-nesting waterbird inventory on 183 wetlands located on NWRs and WPAs in the Long Lake Wetland Management District (Knutsen 2004*). Wetlands were divided into three strata (high, moderate, and low) related to their likelihood of supporting a waterbird colony, based on habitat conditions in 2003, as well as the size and permanence of the wetlands (*sensu* Stewart and Kantrud 1971). Number of nests, number of colonies, dominant vegetation, and the presence of other colonial bird species nesting within colonies were recorded. The ratio of live-to-residual emergent vegetation within colonies and the percent of the colony's area that was composed of residual emergent vegetation and open water were visually estimated. Water depth was not measured in 2003. Vegetation density was classified into one of three categories: dense (heavy, thick stands of emergent vegetation with few visible openings), moderate (contiguous stands of emergent vegetation with numerous small openings), or sparse (large "canoe-sized" openings within the emergent vegetation of open-water floating mat colonies).

TABLE 1. White-faced Ibis colonies in North Dakota for which wetland and colony sizes, vegetation characteristics, and water depths were recorded.

Colony location	Year	Wetland size (ha)	Colony area (ha)[1]	Number of ibis nests or pairs	Dominant vegetation	% open water	% emergent vegetation	Ratio of live-to-dead vegetation	Water depth (cm)	Other species present	Source
Long Lake NWR, Burleigh Co	1978	6932[2]		2-4 nests in 1 colony	*Scirpus* sp.					Yes	Schmidt (1980a)
	2001	325	0.1-1.2	23 nests in 4 colonies	*Typha* spp., *Schoenoplectus* sp.			1:1 at 1 colony, more live than dead at 3 colonies	57-77	Yes	USFWS (2001*)
	2003	325	3.2	7 nests in 1 colony	*Typha* spp.					Yes	Knutsen (2004*)
Krafft Slough, Sargent Co.	1979	380		1 nest	*Typha* sp.				80	Yes	Schmidt (1980a)

	2001	4913	10-27	31 pairs in 3 colonies	*Typha* spp.	20-50	30-50			Yes	Phelps and Meeks (2001*)
Kleppe Lang WPA (Dewald Slough), Kidder Co.	2002	345	2.8, 6.0	11 nests in 2 colonies	*Phragmites australis*, *Typha* spp., *Schoenoplectus* sp.			1:1 at the smaller colony, more live than dead at larger colony		Yes	USFWS (2002*)
	2003	345	6.5	8 nests in 1 colony	*Phragmites australis*, *Typha* spp., *Schoenoplectus* sp.	15	85	9:1		Yes	Knutsen (2004*)

[1]Colony area refers to the area occupied, by nests of all colonially nesting species within the colony, not just to ibis nests.
[2]The wetland size for the 1978 ibis observation includes the entire wetland basin size for Long Lake. The wetland size in 2001 and 2003 reflects the size of an impoundment that did not exist in 1978.

Results

Ibis in North Dakota

The only reported observation of ibis in North Dakota in the nineteenth century was of a specimen that was collected in 1882 and deposited in the University of Michigan's Museum of Zoology (Wood 1923). Wood (1923) also reported the first two occurrences in the twentieth century, including single individuals in Morton County in 1912 and in Slope County in May 1920. The fourth report of an ibis occurred over 40 years later, on 5 June 1961, in Stutsman County (*fide* REM). This observation marked the beginning of the species' documented range expansion into North Dakota (Figure 1). Observations of ibis increased markedly between the 1960s and 1990s. Between 1961 and 2002, the species has been observed nearly annually, occurring in all but nine of the 42 years.

From 1882 to 2002, there were 145 reports of one or more White-faced Ibis in North Dakota, including 93 reports during the breeding season, 49 during the nonbreeding season, and three for which the season of occurrence was not reported. Of the 107 occurrences of the species during the twentieth century, 71 occurred during the breeding season, 34 during the nonbreeding season, and the season of occurrence for two early records was unknown (Figure 1). During the twentieth century, no occurrences were reported from January through March, and two occurrences each were reported in November and December (Figure 2). The earliest observation within a year was 14 April, which occurred in 2002 at Long Lake NWR (46°43'59"N, 100°05'43"W) in Burleigh County (P. C. Van Ningen, U.S. Fish and Wildlife Service, Moffit, North Dakota, personal communication). The latest observation within a year was 17 December 1999 in Sargent County (D. Kinzler, Oakes, North Dakota, personal communication). The largest group of birds observed during the breeding season was about 400 individuals on 11 August 2001 in Sargent County; this group was undoubtedly a post-breeding flock (Martin 2002). The largest group of birds observed during the nonbreeding season was over 50 individuals in September 2000 in Kidder County by H. F. Duebbert (Martin 2001).

From 1912 to 2002, ibises have been sighted in 28 (53%) of the 53 counties in North Dakota (Figure 3). Observations first occurred west of the Missouri River. The two observations in the early part of the twentieth century both occurred in the western part of the state (Wood 1923). Of the eight occurrences in the 1960s, all were reported from southern counties, but only one occurred west of the Missouri River, in Slope County (G. B. Berkey, personal communication). Most observations after the 1960s were east and north of the Missouri River. The first occurrences in the northern half of the state occurred in 1973 at Upper Souris NWR (48°30'11"N, 101°31'50"W), Renville County, by I. O. Rostad (Houston 1974) and in 1974 at J. Clark Salyer NWR (48°40'52"N, 100°47'23"W), McHenry County,

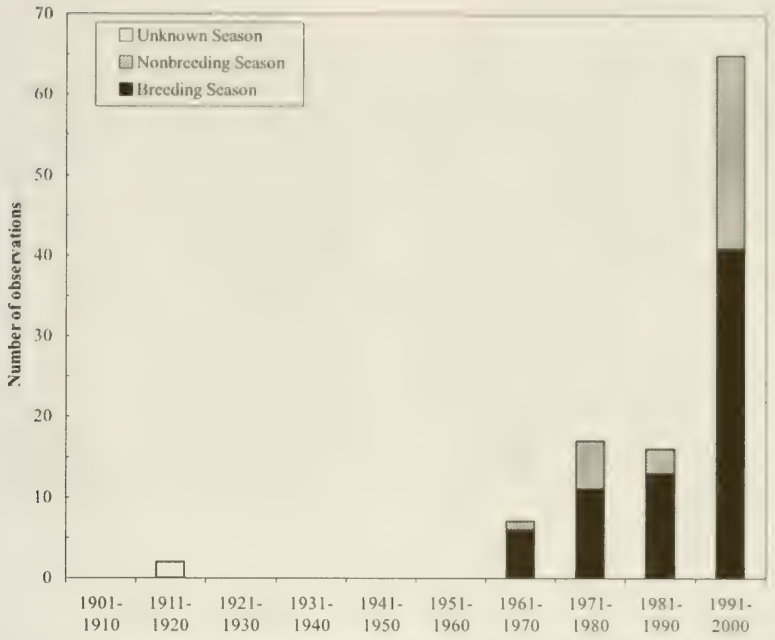

FIGURE 1. Records of White-faced Ibis occurrences in North Dakota during the twentieth century, by decade.

by R. C. Fields (Houston and Houston 1974). The first sightings in five counties (Bottineau, Foster, Mercer, Pierce, and Ward) occurred recently, within 2001-2002.

To date, there are 21 records of nesting activity in North Dakota (Table 2). The first nest was reported by R. A. Schmidt and R. N. Randall in 1978 (Serr 1978; Schmidt 1980a). From 1978 to 2003, nests have been reported in ten of the 26 years, with the majority occurring between 2000 and 2003. Nests or nesting activity have been reported in each of the four recent years from 2000 to 2003. The number of nests discovered within an individual wetland varied from one to 31. All 21 nesting observations were recorded in June, July, or August. Observations in June indicated that nesting had been initiated in May. By August, young or fledglings were observed. Nesting ibises have been observed in eight of the 53 counties (Table 2, Figure 3). Most nesting activity was recorded in Burleigh and Kidder counties (Table 2). Of the ten known wetlands that have contained nesting ibises, six are federally owned; two involve a mixture of federal, state, and/or private ownerships; and two are privately owned.

The ibis has been recorded on a Breeding Bird Survey route in North Dakota in only one year since the survey's inception in 1966. On 10 June 1999, three individual ibis were reported by H. C. Talkington (Mandan, North Dakota, personal communication) on his BBS route south of Tappen in Kidder County. According to banding records, three flightless young were banded in late July 1979, in western Sargent County (K. Klimkiewicz, U.S. Geological Survey, Laurel, Maryland, personal communication). No ibises have been recorded in North Dakota on a Christmas Bird Count, which have been conducted in the state since the early 1900s.

In North Dakota, ibises have been found breeding only in large (>300 ha) semipermanent or permanent wetlands. Colonies, all of which were mixed-species colonies, were located in patches of emergent vegetation dominated by cattails and bulrushes and ranged in areal extent from 0.1 to 27 ha (Table 1). Ibises appeared to prefer a fairly equal proportion of open water and emergent vegetation within a wetland basin, with half or more of the vegetation composed of live rather than residual stems. Water depths varied from 60 to 80 cm. Schmidt (1980a) reported that one ibis nest was built just above the water level in residual cattails interspersed with open water and was located 600 m from shore and 20 m from the central open water area of the wetland basin. Flightless ibises were located in emergent vegetation about 700 m from shore and 35 m from open water. Brice (2003) reported that the mean density of residual cattail stems within an ibis colony was 44 stems/m^2. Knutsen (2004*) found that two of 40 waterbird colonies contained ibis nests. Both of these ibis colonies were located on wetlands categorized as having a high probability of supporting a waterbird colony. One of the colonies was located on an impoundment of Long Lake that contained ibises in 2001, and the other was located on a WPA that contained

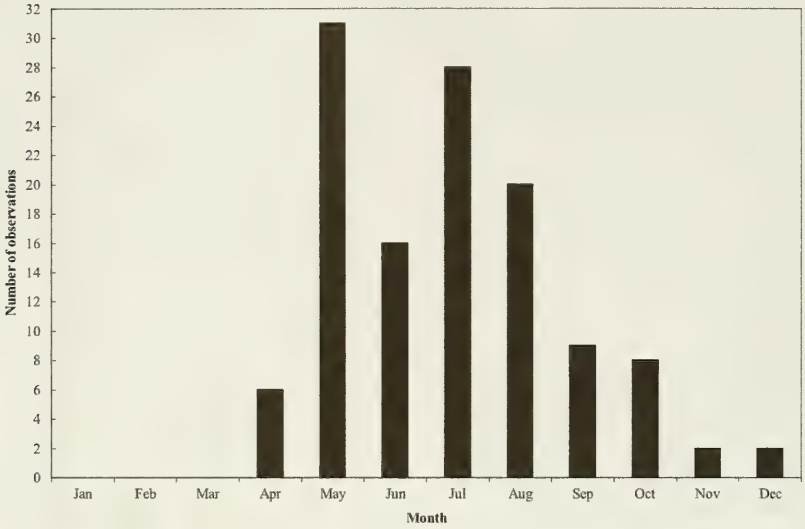

FIGURE 2. Records of White-faced Ibis occurrences in North Dakota during the twentieth century, by month. An observation was counted once, regardless of whether the observation was of one or of multiple individuals.

ibises in 2002 (Table 1). Vegetation density within the colony in the impoundment was categorized as moderate, whereas vegetation density within the colony in the WPA was categorized as dense. Several other waterbird species occurred at colonies with ibises (Table 1). These species included Ruddy Duck (*Oxyura jamaicensis*), Horned Grebe (*Podiceps auritus*), Eared Grebe (*Podiceps nigricollis*), Western Grebe (*Aechmophorus occidentalis*), Clark's Grebe (*Aechmophorus clarkii*), Snowy Egret (*Egretta thula*), Cattle Egret (*Bubulcus ibis*), Black-crowned Night-Heron (*Nycticorax nycticorax*), American Coot (*Fulica americana*), Franklin's Gull (*Larus pipixcan*), Forster's Tern (*Sterna forsteri*), and Black Tern (*Chlidonias niger*) (Schmidt 1980a; Phelps and Meeks 2001*; USFWS 2001*, 2002*; Brice 2003; Knutsen 2004*).

Ibis expansion in the northern prairie and parkland region

There appears to be a consistent pattern throughout the northern prairie and parkland region concerning the chronological progression from the first occurrences to the establishment of breeding colonies (Table 3). From our examination of regional patterns of ibis distribution, we determined that the species rarely visited the northern prairie and parkland region in the late nineteenth and early twentieth centuries and did not develop breeding populations until the late twentieth century. North Dakota, Iowa, and Minnesota reported ibis occurrences as early as the late nineteenth century (Peabody 1896; Lokemoen 1979; Schmidt 1980a; Janssen 1987; Kent and Dinsmore 1996), and Nebraska and Alberta reported occurrences during the early twentieth century (Kondla et al. 1973; Goossen et al. 1995; Mollhoff 2001). Montana, South Dakota, Manitoba, and Saskatchewan did not report ibis occurrences until the mid-to-late twentieth century (Skaar 1969; Serr 1975; DuBois 1989; Goossen et al. 1995; Tallman et al. 2002). The first nests in the region were reported in 1894 in Minnesota (Peabody 1896) and in 1916 in Nebraska (Mollhoff 2001), but other states and provinces did not report nesting ibis until the mid-to-late twentieth century. Two nest records have been reported for Saskatchewan, both of which occurred in 2000 (B. Hepworth, Ducks Unlimited Canada, Regina, Saskatchewan, personal communication; P. Taylor, Canadian Wildlife Service, Environment Canada, Saskatoon, Saskatchewan, personal communication). Bazin and Artuso (2006) documented the first nest record for Manitoba in 2005. Jorgenson and Dinsmore (2005) summarized recent nesting records for Alberta and some of the states in the northern prairie and parkland region. An additional nest record in Alberta was reported by Flockhart (2001).

Discussion

The number of occurrences of ibises in North Dakota reached the point that the North Dakota Birding Society stopped recording new nonbreeding observations after about 2002 (REM, unpublished data). Nesting ibises are becoming increasingly common, with multiple reports of nests every year from 2000 to 2003 (Table 2). Spring arrival in North Dakota typically begins in mid-to-late April, and birds begin departing in September (Figure 2). Few birds remain in the state in November and December, and no records exist for January through March. Nesting occurs from mid-May to late August (Table 2). The ibis appears to nest colonially with other waterbird species as has been report-

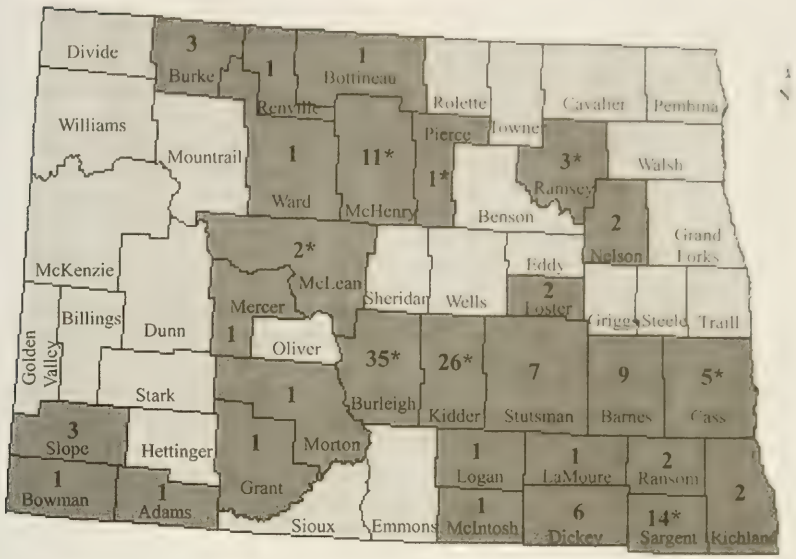

FIGURE 3. Records of White-faced Ibis occurrences in North Dakota during the twentieth century and 2001-2002, by county. Asterisks (*) denote counties in which nesting activity has been observed during the twentieth century and 2001-2003.

ed by other researchers in the northern prairie and parkland region (Peabody 1896; Dinsmore and Dinsmore 1986; Mollhoff 2001). Based on our findings, we believe that the status of ibis in North Dakota is that of a fairly common migrant and a locally uncommon breeder east of the Missouri River and a casual migrant west of the Missouri River.

Of the ten known wetlands that have contained nesting ibis, most are under federal management. These wetlands are protected from drainage and tillage; therefore, thick stands of cattails and other tall wetland vegetation are able to become established in some years (Table 1). These wetlands also may experience higher levels of human visitation than privately owned wetlands. More human visits, either by federal employees conducting biological surveys or by bird watchers and nature enthusiasts visiting the NWRs, WPAs, and other federal properties, could explain the greater number of reports of nesting activity on federally managed properties.

Because ibises were present as vagrants in some parts of the northern prairie and parkland region in the late nineteenth century, several authors have speculated that the presence of breeding colonies in the twentieth century was not so much an expansion of the species' range as it was the reclamation of portions of the species' former range (Ryder and Manry 1994; Dinsmore et al. 1984). Goossen et al. (1995) advanced several explanations for the expansion of breeding ibises into Canada, which included population growth; loss of habitat to draining, flooding, or drought in other portions of the species' breeding range; dispersal; and an increase in suitable habitat due to the advent of managed or restored wetlands and irrigation. The virtual absence of sightings from the late nineteenth century through the early twentieth century in the northern prairie and parkland region (Table 3) coincided with the withdrawal of ibises from inland areas in Texas, suggesting to Jorgenson and Dinsmore (2005) that sightings in northern regions in the late nineteenth century and first half of the twentieth century were linked to fluctuations in the Gulf Coast populations. They examined the historical status of the species from Alberta to Texas and suggested that the current range expansion appears to be unprecedented. They contended that the idea that ibises occupied the northern Great Plains in the nineteenth century was based on only three nesting records that occurred at a time when extralimital breeding of the species was being documented elsewhere in the continent. They suggested that the development of breeding populations of ibises was linked to population fluctuations in the species' core breeding areas of Texas, Louisiana, and, more likely in modern times, to fluctuations occurring in the Intermountain West, the region of North America lying between the Rocky Mountains to the east and the Cascades and Sierra Nevada to the west.

Drawing upon knowledge of habitat, climate, and socioeconomic conditions in the northern Great Plains, using North Dakota as an example, we suggest further explanations for the pattern of ibis observations. Those explanations include habitat perturbations and habitat loss in other parts of the ibis' range, climate and precipitation patterns in the northern prairie and parkland region that impacted habitat conditions, and socioeconomic conditions. We concur with Jorgenson

26 July 2003	Lake Alice NWR	10 pairs	R. E. Martin	this paper
18 August 2003	Unnamed wetland in southern Pierce Co. 47°56'55"N, 100°01'19"W	10 adults, including adults feeding young in nest	R. E. Martin	Martin (2004)

[1] Beyond 2003, U.S. Fish and Wildlife Service personnel no longer quantified colony and nest numbers on NWRs and WPAs.

and Dinsmore's (2005) suggestion that ibis occurrences in the northern Great Plains during the late nineteenth century and early twentieth century may have been due to extralimital wandering as was occurring in other parts of the U.S. at the same time, combined with the species' predilection for post-breeding dispersal north of its nesting grounds (Ryder 1967; Ryder and Manry 1994).

No ibises were reported in North Dakota between 1920 and 1961 (Table 3). Plausible explanations include a scarcity of suitable nesting habitat and a low level of human engagement in nature-based activities. Potential suitable wetland habitat for ibises deteriorated with the onset of drought that characterized the 1930s, the Dust Bowl years (Robinson 1966). Given the duration and intensity of that drought, it is highly likely that suitable wetland habitat was largely nonexistent in the 1930s.

The widespread drought of the 1930s, combined with economic collapse during the Great Depression, resulted in a human exodus from North Dakota (Robinson 1966). The human population in North Dakota reached the highest levels to date, according to the 1930 census, and experienced a 9% decline between 1930 and 1950 (USCB 2005), with much of the decline occurring in rural areas. The human population continues to fluctuate and recovered somewhat from the 1950s, but never has reached the levels experienced prior to the 1930s. During the 1940s, fewer people lived in North Dakota than in the 1920s or 1930s (Kazeck 1956), and some people that remained were called to war or were engaged in war-related activities. During the war, ammunition was rationed and hunting activities were subsequently curtailed. Overall, then, there likely were fewer people afield and thus there were fewer chances of people encountering ibises during this time.

Also during the 1940s, moisture conditions, and thus potential ibis habitat, began to improve, with the highest annual precipitation at Bismarck between 1900 and 2000 occurring in 1941 with 79.1 cm (NCDC 2004*). Concomitant with improved moisture conditions was the invasion into North Dakota of an introduced species of European cattail, the Narrowleaf Cattail (*Typha angustifolia*), which was first collected in North Dakota in 1942 at Long Lake NWR (Kantrud 1992). Prior to that time, there were few cattail-dominated wetlands in North Dakota, and the few stands that did exist were in boggy areas around freshwater lakes (Kantrud 1992). Narrowleaf Cattail was restricted largely to the southeastern portion of North Dakota in the early 1960s and spread to many wetlands in central North Dakota by the 1970s (Kantrud 1992). However, the invasive species hybridized with the native Broadleaf Cattail (*Typha latifolia*), and the resulting hybrid (*Typha* ×*glauca*) spread rapidly throughout the prairie pothole region of North Dakota during the 1950s, becoming the most abundant large hydrophyte in the state (Kantrud 1992). Wetlands dominated by the hybrid cattail potentially provided prime breeding habitat for ibises. Also, despite the decrease in the number

TABLE 3. Pattern for the northern prairie and parkland region, USA and Canada, that exhibits the lapse between time of first White-faced Ibis observations, time of consistent (>5 observations in a given decade) observations, and year of first nest record.

of temporarily flooded wetlands due to drainage, the number of permanent wetlands in the form of basin wetlands and riverine impoundments increased in the state (Lokemoen 1979).

Kantrud (1992) suggested that prairie wildfires and grazing by large ungulates, two major ecological forces during presettlement times, were responsible for the restricted distribution of Broadleaf Cattail prior to the invasion of Narrowleaf Cattail. Many semipermanent wetlands in eastern North Dakota, eastern South Dakota, and western Minnesota that were grazed and that were dominated by semi-open stands of Hardstem Bulrush (*Schoenoplectus acutus*) presently are not grazed and are dominated by dense stands of cattail. Gary Krapu (U.S. Geological Survey, Jamestown, North Dakota, personal communication) recalls that, prior to the mid-1950s in North Dakota, most wetlands experienced grazing pressure by livestock or were hayed. In the late 1950s and 1960s, however, many farmers began to focus exclusively on small-grain production, phasing out livestock production. Livestock were beneficial in stopping the growth of dense stands of cattails by eating young, green cattail shoots. With the loss of grazing pressure, Narrowleaf Cattail more easily became established in wetlands. The decline in farm operations that raised livestock was hastened by the Soil Bank Program in the 1950s, which provided farmers with annual payments under 5-to-10 year contracts to idle their cropland by planting to perennial cover. This program indirectly also encouraged the idling of wetlands as farmers reduced the number of livestock that they produced.

During the 1950s and 1960s in southern portions of the species' breeding range, ibis breeding habitat was being lost due to human encroachment or drought. Breeding colonies of ibises disappeared or decreased in size due to habitat loss or pesticide contamination in Oregon, California, and Nevada (Ryder 1967; Ryder and Manry 1994). This decline coincided with increased sightings in Minnesota, North Dakota, South Dakota, and Montana (Table 3). It is plausible that this highly nomadic species sought and found better breeding conditions in the northern prairie and parkland region than in its more traditional breeding range.

Banding studies during the 1960s found that shooting was the major cause of reported deaths for this species, with many bands recovered from Mexico (DuBois 1989). The species was a gamebird until the early twentieth century, when international treaties conferred protection from hunting or harassment. Lokemoen (1979) postulated that ibis population increases might have been due in part to federal protection. Although federal protection of migratory birds began in 1918 with the signing of the Migratory Bird Treaty (Legal Information Institute 2005*), resources were not available for widespread federal enforcement in North Dakota until the 1940s (G. Krapu, personal communication).

After the late 1960s, pesticide contamination and continued habitat loss occurred in southern states, coinciding with more frequent ibis sightings and first nest records in several northern states. King et al. (1980) monitored eggshell thickness, pollutant residues, and the population status of the species in Texas from 1969 through 1976. They found that nesting populations declined by 42%, associated with low reproductive success caused by DDE-induced shell thinning and dieldrin mortality. Taylor et al. (1989) reported that the ibis population doubled in the late 1970s in Utah and also increased in Oregon. They attributed these increases to flooding in the Great Basin during the early 1980s, recovery from reduced productivity caused by DDT in the 1970s, and/or natural fluctuations in ibis populations.

Other Ciconiiformes species also increased in occurrences and expanded their distribution during the same time period in North Dakota and other areas of the northern prairie and parkland region (Jones and Malcolm 1978; Lokemoen 1979; Schmidt 1979a,b, 1980b; Lambeth 1980). The first Cattle Egret in North Dakota was reported in 1971 (Lokemoen 1979), and the first nesting colony was discovered in 1976 among nests of Black-crowned Night-Herons and Little Blue Herons (*Egretta caerulea*) (Jones and Malcolm 1978). More Cattle Egret colonies were discovered in the ensuing years (Schmidt 1980b). It is possible that the presence of the colonies of Cattle Egret and other colonial-nesting birds provided the stimulus that prompted ibis to establish colonies.

More recently, the increase in White-faced Ibis observations in North Dakota has coincided with the wet conditions experienced in the northern prairie and parkland region from 1993 to the present (NCDC 2004*). The current wet cycle may be the wettest period during the past 130 years (Winter and Rosenberry 1998). These wet conditions may be contributing to suitable habitat conditions for the ibis. Johnson (1994) documented large-scale pioneering expansion of nesting distributions of several species of western North American birds over the last three decades. Although Johnson (1994) did invoke climatic warming as a possible explanation, he believed that it was neither the sole explanation nor even the primary cause. Rather, he hypothesized that many of the species were responding to a decades-long increase in summer rainfall in regions beyond their former ranges, based on regional climatic trends. Summer moisture, perhaps coupled with a higher mean temperature, encouraged avian range expansions. Detailed correlations of local climatic data with temperature and moisture requirements of individual species would be necessary to establish causality (Johnson 1994).

We believe that the combination of adequate rainfall and invasion of Narrowleaf Cattail in the 1940s in North Dakota, the rapid establishment of Narrowleaf Cattail and its hybridization with the Broadleaf Cat-

tail during the ensuing decades, the general expansion of other ciconiiform species, the conversion from ranching to small-grain production, wetland loss and poor ibis reproduction in the southern portions of the ibis breeding range, growing ibis populations in the Intermountain West region, wet conditions suitable for colonial waterbird establishment, and climatic changes have contributed to the growth of ibis populations in North Dakota. We suspect that the above factors also may have played a role in population changes elsewhere in the northern prairie and parkland region. Ibises are considered rare, localized breeders in the northern prairie and parkland region (Beyersbergen et al. 2004) and, more specifically, are considered locally uncommon in North Dakota (this paper), rare to locally uncommon in South Dakota (Sabo 1992), and a rare summer resident in Canada (Goossen et al. 1995).

The future status of ibis within the northern prairie and parkland region likely will depend upon precipitation patterns. With continuing years of adequate rainfall, wetlands that harbored colonies should continue to provide suitable habitat. There are no indications that the spread of monotypic stands of cattail within wetlands will abate, which should only aid in the spread of ibis into new breeding areas. Already, breeding sites in North Dakota that once contained only a few birds and nests now contain larger groups of nesting birds. With an onset of a prolonged drought, the quality of nesting habitat could decline in some wetlands, but water levels in other wetlands that had been inundated to the degree that they no longer supported emergent vegetation would recede and again allow the growth of deep-marsh vegetation that could harbor new nesting colonies. Even in a prolonged drought, colonies could persist at managed wetlands, such as those maintained within certain NWRs. From these colonies, ibis could disperse when precipitation levels again rise at previously dry wetlands.

Acknowledgments

We thank the many individuals who have contributed records of White-faced Ibis in North Dakota. We thank Richard Crawford, Todd Grant, Dave Griffiths, Craig Hultburg, Lawrence Igl, Will Meeks, and Mike Norton for providing detailed information on unpublished sightings. Will Meeks of the U.S. Fish and Wildlife Service procured funding and equipment for Joel Brice's graduate field research, and Richard Crawford served as his graduate advisor. Kathy Klimkiewicz of the Bird Banding Laboratory provided information on ibis banding records. Special thanks to Gary Krapu for sharing his knowledge and experiences of North Dakota birdlife and to him and Lawrence Igl for prompting discussions on factors relating to ibis population increases. Thank you to Rachel Bush for conducting library searches. Early drafts of the manuscript were reviewed by Steve Dinsmore, Lawrence Igl, Douglas Johnson, Gary Krapu, and Terry Shaffer.

Dubois, John E., and Kimberly M. Monson. 2007. Recent distribution records of the Little Brown Bat, *Myotis lucifugus*, in Manitoba and northwestern Ontario. Canadian Field-Naturalist 121(1): 57-61.

Until recently, the distribution of the Little Brown Bat (*Myotis lucifugus*) in Manitoba and northwestern Ontario was poorly documented. Since 1988, we have been banding and recapturing little browns throughout Manitoba and adjacent Lake of the Woods region in Ontario. All known hibernacula in the study area are recorded here for the first time, along with time of emergence. Connections between some hibernacula and summer nurseries are verified by band returns, ranging from 37 to 540 km.

Key Words: Little Brown Bat, *Myotis lucifugus*, distribution, Manitoba, northwestern Ontario.

We began our study of the Little Brown Bat *(Myotis lucifugus)* in 1988. The objectives of the study were: (1) to map the distribution of Little Brown Bats in Manitoba; (2) to find as many hibernacula and summer nursery roosts as possible; (3) to learn where bats found in hibernacula spend the summer; and (4) where bats found in summer roosts spend the winter. An overriding objective has been to encourage awareness and conservation of bats among the public and responsible agencies in Manitoba. All work was done under Manitoba Conservation "Wildlife Scientific Research", "Ecological Reserves Research", and Ontario Ministry of Natural Resources (Kenora District) permits issued to Dubois.

Little previous research had been done on the six species of bats known to occur in Manitoba (Banfield 1974). Robert Barclay worked on some species and made incidental observations of occurrences and migration dates of little browns at the University of Manitoba Delta Marsh Field Station from 1981 to 1983 (Barclay 1984). Barclay (1993) stressed "Even for species that are well studied elsewhere, such as the Little Brown Bat, information about the biology of prairie populations is scarce. More than anything else, it is this lack of information that hinders conservation efforts for prairie bats." This study is meant to aid conservation efforts by filling gaps in our knowledge.

A. L. Rand (1948) reported sightings of the Little Brown Bat in the Flin Flon district. J. Dewey Soper (1961) reported the first specimens taken at Max Lake, in Turtle Mountain Provincial Park, 20 August 1949. Little browns were reported from the Delta area (Tamsitt 1962). In 1978 the late Walter Cook of Grand Rapids showed provincial biologist Bill Koonz a couple of caves north of the town that over-wintered bats (Koonz, Manitoba Conservation, personal communication). Since 1988 systematic searching for caves with the Speleological Society of Manitoba (SSM) has produced more information on the Little Brown Bat in Manitoba. Soliciting the public and various agencies to report caves, summer bat roosts and sightings has also been very productive.

Methods

We banded Little Brown Bats to monitor their distribution and seasonal movements. Plastic coloured bands were used in the first year of banding, 1988. Each cave or location was identified by a different colour. For more precise tracking of individual bats and their movements, numbered aluminium bands (National Band & Tag Co., Kentucky), size 2 were used in 1989 and thereafter.

Hibernacula were located with the aid of the considerable efforts of the members of the Speleological Society of Manitoba and other volunteers. Starting from reported hibernacula sites, the authors and other members of the SSM used a combination of surficial geology, topographic maps, and air photos to identify likely areas for methodical ground searches. Karst features such as caves, sinkholes and trenches were detected on air photos in areas where limestone, dolomite and gypsum bedrock are near the surface. These areas were then visited and searched in a grid pattern, using map and compass, and latterly, hand-held global positioning system (GPS) units.

Information provided by home and cottage owners, Manitoba Department of Conservation, Ontario Ministry of Natural Resources, and other agencies led to the banding of bats in residential and cottage summer nursery colonies throughout the province, spilling over into adjacent northwestern Ontario around the north end of Lake of the Woods.

Greatest frequency of banding occurred in caves in the Grand Rapids and Gypsumville areas, and in one large cave (St. George Cave) north of Hodgson. [See map, Figure 1] The karst features, where the caves are found in gypsum and dolomite formations of these areas, are

described in detail in the field reports of the Manitoba Mines Branch for 1988, 1989 and 1990 (e.g., Sweet et al. 1988) and in McRitchie and Monson (2000).

We used standard techniques to capture and band the bats (Kunz and Kurta 1988). We captured them in caves by plucking the torpid bats carefully by hand from the cave wall, and placing them in a cloth bag. We live-trapped Little Brown Bats with a harp trap (Tuttle 1974). Once captured, the bats were examined to determine sex, reproductive status, age, injuries (both healed and fresh), and, on a cursory basis, external parasites present. According to custom (Kunz and Kurta

FIGURE 1. Map of Manitoba showing the portion of the Boreal Ecozone and major settlements. Circles are settlements, triangles are other localities (see text).

1988), we banded males on the right forearm and females on the left. Those bats found to be previously banded were duly recorded and injuries and/or parasites noted. Time in capture and handling was kept to a minimum to avoid stressing the animals. Banding locations are summarized in Tables 1 and 2, below.

Many of the Manitoba caves containing bats were mapped, the annual maximum and minimum temperatures recorded (average +5°C) and any other vertebrate or invertebrate inhabitants noted, by us, other SSM members, and by staff of the Manitoba Museum and the Manitoba Geological Survey. These details and more on the caves and surrounding landscapes are thoroughly described in McRitchie and Monson (2000).

Results

To date we have banded more than 9000 Little Brown Bats. J. Dewey Soper (1961) speculated that Little Brown Bats "probably extend almost to the Hudsonian Zone", now called the Boreal Shield ecozone (Ecological Stratification Working Group 1995), while van Zyll de Jong (1985) stated: "It is found from the Atlantic to the Pacific coast and occurs to the limits of the boreal forest."

In addition to those locations where banding has taken place (Tables 1 and 2), we have verified the presence of this species throughout southern Manitoba and at least to the latitude of Taiga Biological Station, University of Manitoba, Wallace Lake (51°01'50"N), east of Lake Winnipeg (Table 3). On the west side of the province, Little Brown Bats occur to the latitude of Sherridon (55°07'26"N), and in north-central parts of the province to Setting Lake (55°04'11"N) (Table 3) – locations slightly north and just south of Herb Lake (reported in van Zyll de Jong 1985, page 70).

Similar to many species across Canada, a combination of degree-days and night-length likely constrains their range in the north – see discussions in Holroyd et al. (1994), Nagorsen and Brigham (1993), Humphries et al. (2002). A maternity roost of Little Brown Bats was reported recently at 58°06'36"N on the Alaskan coast (Parker and Cook 1996), as was one at Squanga Lake, Yukon at 60°28'40"N (Jung and Slough 2005) .

Sherridon (55°07'26"N) is the site of the northernmost nursery colony we have found in Manitoba to date, while Okaw Cave (53°51'53"N) is the northernmost hibernaculum. Individual Little Brown Bats have been reported during summers from as far north as Thompson (55°44'36"N). Little browns have been reported to us as showing up at summer nursery colonies in central and southern Manitoba as early as the last week in April, and more often, the first week of May. However, we routinely find large numbers of a given hibernaculum still in torpor when entering the caves in the Grand Rapids area on the Victoria Day long weekend in May (normally the third weekend of the month, range 17-28 May).

Band returns from this study have shown little browns are very loyal to both their summer and winter roosts, with very low incidences of transference (>1%). Recoveries from subsequent, different roosts ranged from 5 km to 533 km distant from point of original banding. Seasonal migration distance from hibernacula to summer nursery colony for adult females ranged from 37 km to 540 km. Details of inter-roost and seasonal movements will be published separately.

We started banding Little Brown Bats around Lake of the Woods (mainly in the Kenora area) in 1993 to learn whether those populations use Manitoba caves to hibernate. Band returns demonstrate that at least some of those females forming nursery colonies in that region definitely use central Manitoba caves to over-winter, as well as one nearby abandoned mine. It has been speculated for some time that abandoned mines in the Kenora area have served as hibernacula (Nagorsen 1980). In July 1995, we were directed to an abandoned mine at Richard Lake, 37 km east of Kenora and, upon returning in late September, found it to contain at least 250 Little Brown Bats, none previously banded. In the Richard Lake hibernaculum in subsequent years we recaptured banded bats from nursery colonies on Lake of the Woods (Keewatin, French Portage Narrows, Rushing River Provincial Park), as well as bats previously banded in Manitoba hibernacula as far as 533 km away (St. George, Iguana Crypt and Microwave caves).

Conservation

This study has verified that at least 11 caves in Manitoba and one abandoned mine in northwestern Ontario serve as hibernacula for Little Brown Bats (Table 1). Bats of many species are at their most vulnerable at roost sites, particularly hibernacula (Brigham 1993). The largest hibernaculum discovered to date in Manitoba, by several orders of magnitude, is St. George Cave, 200 km north of Winnipeg. More than 20 000 little browns spend each winter in that cave. This critical cave and a small area around it was declared an ecological reserve by the Province of Manitoba on 15 March 1997, after several years of effort by Willard Anderson, the authors, and other members of the Speleological Society of Manitoba. This is the most stringent legal protection a natural feature can get in this province. The Province of Manitoba, on 15 January 1996 officially declared six species of bats to be "a wild animal" under *The Wildlife Act* (by the Designation of Wild Animals Regulation MR 3/96), as a first step in their protection. As of December 1997, Manitoba Department of Natural Resources (now Conservation) has issued guidelines to direct all activities occurring on Crown land around the known over-wintering caves (Asmundson and Larche 1996*).

Acknowledgments

We thank our employers, the Manitoba Museum and the University of Winnipeg, for their support during the majority of the time period of this study. Additional funding was granted by the Manitoba Museum Foundation Fund. We were also substantially assisted by the

staff of Manitoba Department of Conservation (Natural Resource Officers, Operations Branch, particularly of the Grand Rapids and Gypsumville offices, as well as Parks and Natural Areas Branch), and Manitoba Geological Survey, Department of Industry, Trade and Mines. Thanks to Tolko Industries Ltd. and the hospitable people of Grand Rapids and Gypsumville. Many family members and friends have worked with us for many hours. We would like to particularly thank Dale Brown and David Wright. Other volunteer banders and helpers over the years include Al Bisset, Melanie Dubois, Michelle Bell, Liza McClintock, Marie Voth, Lori Bilecki, Christy McDonald, Marg Rubin, Gloria Goulet, Cecile Foster, Janis Klapecki, Dennis Peristy, Kim Ottenbreit, Victoria Shemeliuk, Mike Claussen, Justin Harrison, Donna Kurt, Rick Nash, Paul Buisson, Robert Senkiw, Jocelyn Hildebrand, Marianne Setliff, Chris Caslake, Bob Gill, Darren Keam, Amy Barker, Lidi Kuiper, Lyndon Kivi, Kevin Campbell, Christine Abraham, John Fitzmaurice, Lisa Lagerge and Trapper John Christie. We thank Jim Duncan and Robert Nero for reviewing an earlier draft of this paper.

Immobilization of Elk, *Cervus elaphus,* with Telezol and Xylazine and Reversal with Tolazine or Yohimbine

Rick Rosatte

Ontario Ministry of Natural Resources, Wildlife Research and Development Section, Trent University, DNA Building, 2140 East Bank Drive, Peterborough, Ontario K9J 7B8 Canada; e-mail: rick.rosatte@ontario.ca.

Rosatte, Rick. 2007. Immobilization of Elk *(Cervus elaphus)* with telezol and xylazine and reversal with tolazine or yohimbine. Canadian Field-Naturalist 121(1): 62–66.

During January 2003 and March 2005, a Telazol®/xylazine mixture was used to immobilize 4 free-ranging Elk in Ontario, Canada. A dosage of 3.3-3.6 mg/kg of Telazol® and 1.7-2.0 mg/kg of xylazine proved to be effective for the rapid immobilization of Elk. Induction time for those dosages was as short as 3-4 minutes. The advantage of using Telazol® is that only small volumes (3-4 ml) are needed to immobilize Elk-sized animals. In addition, Tolazine® and yohimbine both proved to be effective antagonists for xylazine with recovery times of 8 to 15 minutes when administered at dosages of 3.3-3.6 and 0.08-0.14 mg/kg, respectively. The use of oxygen proved to be effective for treatment of hyoxemia in Elk immobilized with a Telazol®/xylazine mixture. The immobilization procedures and the drug and antagonist dosage information will be useful to researchers planning to capture free-ranging Elk for activities such as radio-collaring and blood sampling.

Key Words: *Cervus elaphus,* Elk, antagonist, immobilization, reversal agent, Telazol®, Tolazine, Yohimbine, Ontario.

During 1998 – 2001, 443 Elk (*Cervus elaphus*), also known as American Elk, or Wapiti, were transported from Elk Island National Park (EINP), Alberta, and released in four areas of Ontario, Canada (Bellhouse and Rosatte 2005; Rosatte et al. 2007). One of the release sites, near Bancroft, Ontario (approximately 44°5'N, 77°30'W), received 120 Elk during 2000 and 2001. All Elk were aged and weighed at EINP during processing, which included ear-tagging and fitting the Elk with telemetry collars (VHF and GPS) (Rosatte et al. 2002). The weights of Elk at EINP were used as guidelines to estimate the weight of Elk in Ontario for drug dosage calculations.

As ten of the Elk were fitted with GPS collars during processing at EINP, some of the animals had to be immobilized to retrieve the collars and download the data. On 16 January 2003 (-20°C), an 8 year old, free-ranging adult cow Elk (ear tag 341), previously fitted with a GPS collar (148.188 Mhz) at EINP, Alberta, was immobilized with Telazol® (tiletamine hydrochloride and zolazepam hydrochloride) (Fort Dodge Animal Health, Fort Dodge, Iowa) and AnaSed (xylazine hydrochloride) (Vet-A-Mix, Shenandoah, Iowa) near Bancroft, Ontario, for the purpose of collar removal. The drug dosage (target dosage was about 3 mg/kg Telazol® and approximately 1.5 mg/kg of xylazine) was calculated using an estimated weight for the Elk of 236 kg – her weight during processing at EINP in January 2001. The immobilizing drug mixture was prepared by injecting the desired volume and weight of xylazine into a bottle containing lyophilized Telazol®. The Telazol®/xylazine mixture was then drawn off with a syringe and injected into the immobilization dart. The dart was then plugged with vasoline to prevent the leakage of drugs from the dart. A Model 193 Pneu-Dart 50 caliber rifle and 4× scope (Pneu-Dart Inc., Williamsport, Pennsylvania) with a yellow CCI 22 caliber brass power charge (Omaha Industries, Lewiston, Idaho) and a diffuser setting of 4, was used to project a 50 caliber, 4 cc aluminum type C dart with a 3 cm long barbed needle (Pneu-Dart Inc., Williamsport, Pennsylvania), that contained the Telazol®/xylazine mixture, into the hind leg musculature of the Elk. The distance of the shot was about 35 m. As soon as the animal was in a lateral recumbent position and there was no evidence of leg or eye reflex, she was moved into a sternal recumbent position and the head was elevated to minimize the chance of bloat and regurgitation of rumen contents. Ophthalmic ointment was applied to the eyes of the immobilized Elk to prevent drying. The respiration rate of the cow Elk was about 18/min at 30 min post-darting. At 36 min post-darting, the respiration rate increased to 54/min and breathing was very shallow. At this point, bloat was evident and the gum/ tongue area was blue in color (indicative of low oxygen content in the blood). The animal was administered oxygen orally as a treatment for hypoxemia, as well as rolled side to side in an effort to relieve the bloat. The head was elevated and lowered as well to stimulate belching. At 50 min post darting, respiration rate decreased to 42/min and the tongue/gum area returned to a pinkish color following the administration of oxygen. Hibitane antibacterial veterinary ointment (1% chlorhexidine acetate) (Ayerst, Guelph, Ontario) was applied to the dart wound. After the animal was processed an intramuscular injection of Tolazine (tolazoline hydrochloride, Lloyd Laboratories, Shenandoah, Iowa) was administered in the right leg musculature to speed recovery. The concentration and dosage of drugs as well as the induction, down and recovery times are shown in Table 1. After the animal was in a standing position, she orally expelled gas for several

seconds and the bloat decreased dramatically. The Elk was monitored for the next few days and no adverse effects were noted. She was still in good health when observed near Bancroft, Ontario in April 2005.

On 19 February 2004 (-6°C), a 10.5 year old cow Elk (ear tag 360) was immobilized near Bancroft, Ontario, to remove a GPS collar (149.560 Mhz). The weight of the animal at EINP during January 2001 was 234 kg. The animal was darted with a mixture of Telazol®/xylazine as described above using a Pneu-Dart rifle, with a yellow 22 caliber power charge and a diffuser setting of 3, and a 4 cc dart. The distance of the shot was about 25 m with the dart hitting the right upper hind leg musculature. As the drug took effect the Elk assumed a recumbent position beginning with the hind end first (Figure 1). Some bloat was evident so oxygen was administered for treatment of hypoxemia and the animal was rolled from side to side and the head elevated to expel gases (Figure 2). Respiration rate increased from about 14/min to 70/min when bloating occurred. The gums and tongue remained pink colored throughout the handling period. When processing was complete, Tolazine was injected intramuscularly to reverse the effects of xylazine and speed recovery from the drug. Induction, immobilization and recovery times are noted in Table 1.

On 11 January 2005 (-17°C ambient temperature), a yearling bull Elk, born in Ontario, suspected of being infected with meningeal worm (*Parelaphostrongylus tenuis*), was immobilized with an intramuscular injection of Telazol® and xylazine hydrochloride for the purpose of collecting a blood sample. The dosage of drug was calculated using mean weights of yearling bull Elk at EINP. As the Elk had no fear of humans, possibly due to the effects of *P. tenuis*, the drugs were administered intramuscularly in the right upper hind limb area via a 5 cc sterile syringe (Burron Medical Products, Bethlehem, Pennsylvania, USA) and 22 g (4 cm) needle (Terumo, Belgium) attached to a jab stick made from a piece of copper tubing. When processing was complete, which included radio-collaring (148.412 Mhz) and ear-tagging (#139) (as reported in McIntosh et al. 2007), the Elk was injected intramuscularly in the hind limb musculature with Yobine (yohimbine hydrochloride) (Lloyd Laboratories, Shenandoah, Iowa, USA) as a reversal agent for xylazine. Drug dosages, induction, immobilization and recovery times are presented in Table 1. While immobilized, respiration rate for the yearling bull Elk was 14-16/min, there was no evidence of bloat, and the gums and tongue remained pink in color.

On 30 March 2005 (+5°C ambient temperature), a 2½ year old bull Elk (born in Ontario) was immobilized with Telazol® and xylazine for the purpose of de-antlering as the animal had broken the pedicle in the fall of 2004. The drugs were administered as described above using a Pneu-Dart rifle, with a green 22 caliber power charge, a diffuser setting of 5, and a 4cc dart. The distance of the shot was about 30 m with the dart hitting

[a] AF = Adult Female; YM = Yearling Male; AM = 2 ½ yr old Male.

[b] Weight was estimated using weights of Elk at EINP and body size and age of elk.

[c] Concentration of drugs were: Telazol® - 100 mg/mL; Xylazine – 100 mg/mL; Yohimbine 2 mg/mL; Tolazine – 100 mg/mL.

[d] Induction time is the time from drug administration to when the animal was in lateral recumbency.

[e] Down time is the time from when the animal was first immobilized until it was in a standing position.

[f] Recovery time is from the time when the reversal agent was injected until the animal was standing.

[g] 10 min is an overestimate of induction time as the animal was not be located in the forest until 10 minute after darting.

FIGURE 1. A GPS collared adult cow Elk (ear-tag 360) exhibiting hind limb paralysis 2 minutes after being darted with a mixture of Telazol® and Xylazine. (Photo by R. Rosatte).

the right upper hind leg musculature. Respiration rate was stable at about 12/min during processing (de-antlered and ear-tagged – #141) and the gums and tongue remained pink colored with no evidence of hypoxemia or bloat. A 3 cc intramuscular injection of Dystosel (Vitamin E – 136 IU/mL and selenium – 3 mg/mL) (Pfizer Canada Inc, London, Ontario) was administered as a preventative measure against capture myopathy. When processing was complete, Yobine was injected intramuscularly to speed recovery from the effects of xylazine. Induction, immobilization and recovery times are shown in Table 1.

Discussion

A dosage of 3.3-3.6 mg/kg (body weight) of Telazol® and 1.7-2.0 mg/kg of xylazine proved to be an effective drug combination for the rapid immobilization of four free-ranging Elk in Ontario. Induction time or the time from darting until the animal was prone for those dosages was 3-4 minutes. This calculation did not include the Elk for which induction time was noted as 10 minutes, as that animal was not immediately located in the forest. Similarly, Millspaugh et al. (1995) reported a mean induction time of 4.6 minutes when Elk were immobilized with 2.5 mg/kg Telazol® and 0.3 mg/kg xylazine. The advantage of using a Telazol®/xylazine mixture over a drug combination such as ketamine hydrochloride (at a commercially available concentration 100 mg/mL)/xylazine is that a much lower volume of Telazol is required to attain a state of immobilization. For example, only a 4 mL (800 mg of Telazol® reconstituted in 3.5 mL of xylazine) volume of drug was required to immobilize a 225 kg cow Elk. About 15 mL of a ketamine hydrochloride/xylazine hydrochloride (100 mg/mL ketamine) mixture was required to immobilize a bull Elk in Ontario during 2003. The advantage of a smaller volume of Telazol®/xylazine mixture is that a much smaller dart can be used (4 cc compared to a 10 or 15 cc) to administer the drugs, which means less weight and less damage to the animal when the dart is administered via an immobilization gun. A smaller dart (4 cc) has a better trajectory and is more accurate at longer distances (> 65 m) than a larger/heavier dart (10-15 cc). In addition, as the induction time for ketamine in Elk is generally longer than that for Telazol®, animals tend to move farther before being completely immobilized (Golightly and Hofstra 1989; Miller et al. 2004), which could result in problems locating the animal in heavily forested areas.

FIGURE 2. Oxygen being administered to the immobilized cow Elk (ear tag 360) for treatment of hypoxemia (Photo by R. Rosatte).

One drawback with using a Telazol®/xylazine mixture for the immobilization of Elk is the extended recovery time which could lead to decreased survival. In one study, an Elk immobilized with a Telazol®/xylazine mixture was not administered an antagonist and was immobilized for 5 hours (Golightly and Hofstra 1989). As well, there is no known antagonist for the tiletamine component of Telazol® (Miller et al. 2004). Tolazine and yohimbine both proved to be effective antagonists for xylazine with recovery times of 8 to 15 minutes when administered at dosages of 3.3-3.6 and 0.08-0.14 mg/kg (body weight), respectively. However, the key to rapid recovery was administering the antagonist 45-60 minutes (or longer) post -immobilization. This allowed sufficient time for Telazol® to be metabolized and diminish side-effects after injection of the reversal agent. Animals may stagger for some time due to the effects of Telazol® if the antagonist is administered too soon after immobilization as the antagonist only neutralizes the effects of xylazine. Millspaugh et al. (1995) reported a mean recovery time of 14 minutes when yohimbine was administered intravenously to reverse xylazine administered to Elk at a dose of 0.3 mg/kg (in a mixture with Telazol® at a dose of 2.5 mg/kg). However, a recovery time in that study of 125 min was reported when yohimbine was given intramuscularly.

Hypoxemia or deficient oxygenation of the blood may occur during the immobilization of wild ruminants. This can lead to organ failure and capture myopathy (Read et al. 2001). Bloating occurred in two of the Elk immobilized in this study despite their being in a sternal recumbent position. As well, respiration rate was high in those two Elk {normal respiration rate for elk is about 13 breaths/min (Hudson and Haigh 2002)}. Bloat is a result of gas production in the rumen, which may result in pressure being applied to the diaphragm (due to the weight of the abdominal viscera on the diaphragm) with resultant respiratory/circulatory problems and oxygen depletion in the blood. Bloating in this study may have been aggravated due to the animals foraging at feeding stations (with alfalfa) prior to darting. Oxygen quickly relieved the symptoms of hypoxemia (blue tongue, lips), and the suggested rate of oxygen administrated nasally for preventing hypoxemia was 10 L/min for a period of about 5 minutes (Read et al. 2001).

The four immobilized Elk were later (1 month to 2 years) located by radio-telemetry and had recovered fully, with no observable side effects from immobiliza-

tion or handling. Capture procedures, drugs and antagonist data outlined above will be useful to researchers planning to capture free-ranging Elk. For "off-label" use of the above drugs on wild animals such as Elk, an "Emergency Drug Release Authorization" must be approved by the Veterinary Drugs Directorate, Health Canada, and animals immobilized with agents such as Telazol® are not to be used as food items.

Acknowledgments

The Ontario Elk Restoration program is supported by the Provincial Elk Technical Team and the Ontario Ministry of Natural Resources (OMNR), Wildlife Section, and the Wildlife Research and Development Section (WRDS). Thanks to Tom Simpson and Mike Scafie, OMNR, Bancroft District; John O'Donnell, Barry Wannamaker, Ryan Cavanaugh, Jason Langis, Bancroft Elk Program; Jim Young, Provincial Elk Program Coordinator; and Terese McIntosh and Arthur Dupuis, Trent University, for assisting with the immobilization and processing of the elk. Special thanks to Joe Neuhold for all of his assistance and dedication to the Elk Program. Thanks to Norm Cool and Rob Kay, Parks Canada, EINP, Alberta, and Bruce Chisholm, Canadian Food Inspection Agency, Edmonton, Alberta, for weighing and aging the elk during processing at EINP. J. C. Davies and Mike Allan, OMNR, WRDS, reviewed the manuscript and provided helpful comments.

Morneau, François, Benoit Gagnon, and Sydney Whiskeychan. 2007. First confirmed breeding of the Marbled Godwit, *Limosa fedoa*, in Québec. Canadian Field-Naturalist 121(1): 67–70

The objectives of this study were to confirm breeding of the Marbled Godwit (*Limosa fedoa*) in Rupert Bay, on the Quebec coast of James Bay, and to assess population abundance. Nest search was conducted 17–20 June 2003, using several techniques. Two nests were found in the high marsh of Cabbage Willows Bay: these are the first confirmed breeding records of this species in Québec. The Rupert Bay region probably holds a breeding population of no more than a few dozen pairs.

Cette étude visait à confirmer la reproduction de la Barge marbrée (*Limosa fedoa*) dans la baie de Rupert située sur la côte est de la Baie James (Québec) et à estimer l'abondance de la population. Une recherche de nids a été réalisée entre le 17 et le 20 juin 2003 à l'aide de différentes techniques. Deux nids ont été découverts dans le haut marais de la baie Cabbage Willows. Ils confirment pour la première fois le statut nicheur de cette espèce au Québec. La région de la baie de Rupert abrite probablement une population nicheuse d'au plus quelques douzaines de couples.

Key Words: Marbled Godwit, *Limosa fedoa*, nest search, breeding, abundance, James Bay, Rupert Bay, Cabbage Willows Bay, Québec.

The Marbled Godwit (*Limosa fedoa*) breeds only in North America, in three disjunct areas: the grassland of the northern United States and southern Canada, the Alaska Peninsula, and James Bay (Gratto-Trevor 2000). The James Bay area probably holds only 1000–2000 birds (Gratto-Trevor 2000), but the species breeding has been confirmed only in Ontario (Morrison et al. 1976; Peck and James 1983; Morrison 1987).

In Québec, the species was first recorded on the James Bay coast by Spreadborough (*in* Macoun and Macoun 1909), who stated that the species bred on both coasts in 1904, although no direct evidence for breeding was reported. The Marbled Godwit was not recorded again on the east coast of James Bay before 1990. Since then it has been observed during the breeding season in and near Rupert Bay (Létourneau and Morrier 1996). Breeding behaviours were noted there in 1990 and 1991, but nesting was not confirmed.

In 2003, as part of the Eastmain-1-A and Rupert diversion hydroelectric project environmental studies, we sought to clarify the breeding status of the Marbled Godwit in Rupert Bay, on the Québec side of James Bay. The objectives of this study were to confirm breeding of the species in Québec and to assess population abundance.

Study Area and Methods

Field work was carried out in the coastal wetlands of Rupert Bay, Québec, Canada (Figure 1). These wetlands are particularly well developed owing to the sandy deposits and flat landscape. They are especially extensive in Cabbage Willows Bay, which opens into Rupert Bay, and Boatswain Bay, which opens directly into James Bay, but are narrower in Hall Cove and elsewhere. They consist, in sequence from upland to open water, of swamps, fens, high marshes and low marshes (FORAMEC 2004*). The high marsh grounds are somewhat spongy but not covered by water. Low marshes are covered twice daily by the tide but the other wetlands are flooded only by storm tides and equinoctial tides.

Nest searches were conducted on 17–20 June 2003, using several techniques. The rope-drag method (Klett et al. 1986) was used on 0.3–1.4 km transects in parts of the high coastal marsh of Cabbage Willows Bay and Hall Cove. Nests were also searched for in the same areas by watching birds flying from the low marsh to potential nesting areas or vice versa. In addition, playbacks of taped breeding calls were used regularly on the high marsh and once in the low marsh. Finally, to increase ground coverage, we conducted a helicopter survey in Cabbage Willows Bay, in Hall Cove, over some Tamarack (*Larix laricina*) fens on Ministikawatin Peninsula, and on Jacob Island, north of Rupert Bay. We searched along 50-m parallel transects, at speeds that varied from 20 km/h to hover, and at altitudes varying from 3 to 9 m.

Breeding chronology was estimated assuming a mean egg-laying interval of 2 days and an incubation period of 25 days (Gratto-Trevor 2000). Abundance was estimated with counts of birds performing aerial display and nests.

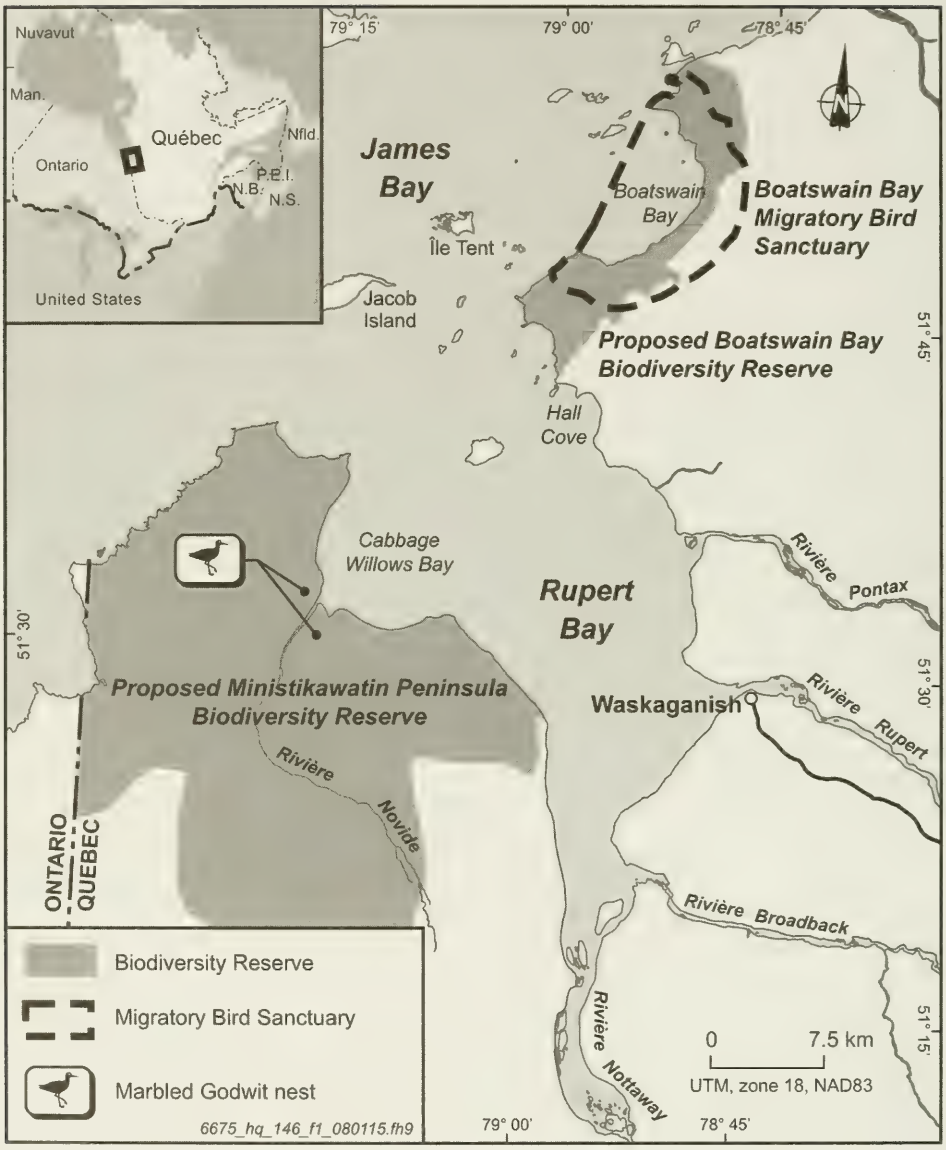

FIGURE 1. Location of Marbled Godwit study area and nests.

Results

The Marbled Godwit nest search was conducted on slightly over 20 km of line transects using the rope-drag method. It covered about 70 ha.

Two Marbled Godwit nests, 3.6 km apart, were discovered in the high coastal marsh of Cabbage Willows Bay in 2003 (Figure 1). The first nest (51°32.61'N, 79°16.13'W), containing four eggs (Figure 2) and one adult incubating, was found on 17 June using the rope-drag technique. The second nest (51°30.77'N, 79°15.13'W), discovered on 20 June following observation of courtship behaviour, contained only one egg, but two adults were within 30 m of the nest. The first nest was revisited again on 19 June and still contained four eggs.

Nests were 5 cm in depth and 20 cm in diameter at the rim. They were mostly, if not completely, made of dry stems of Sweet Grass (*Hierochloe odorata*). Both nests were found in the largest clumps of that species in the vicinity. The first nest was partly covered by

FIGURE 2. First Marbled Godwit nest discovered in Rupert Bay, Québec.

green stems. Throughout the high coastal marsh, grass cover, about 10–15 cm tall, was relatively sparse, with occasional clumps up to 15–25 cm.

In 2003, laying and potential incubation in Cabbage Willows Bay occurred at least between 11 June and 19 July.

No Godwit responded to several playback trials in the high coastal marsh. However, two individuals answered spontaneously to the single trial on the low coastal marsh, by flying and calling around the investigators. Over the same biotope, four different birds were seen engaging in aerial courtship behaviour during nest searches. Besides the birds associated with the nests, only one Marbled Godwit was seen in the high marsh: it was flying from the low marsh and landed in the high marsh, on a potential nesting area. Despite a long search, it was not seen again.

Partial aerial coverage of the Cabbage Willows Bay low coastal marsh enabled us to identify four adults. Another bird was spotted as it flew toward the low marsh during the aerial survey; it seemed to be coming from the second nest area. No birds were seen in Hall Cove or in Ministikawatin Peninsula or Jacob Island during aerial surveys.

Discussion

The two Marbled Godwit nests that we found in Cabbage Willows Bay represent the first definitive breeding evidences of this species in Québec. Some previous observations had led us to believe the species was nesting there. On 17 June 1991, two copulating birds were observed in Cabbage Willows Bay. The same year, three Marbled Godwits were seen on 21 July in the same area, including two agitated birds giving alarm calls, indicating the probable presence of young (Létourneau and Morrier 1996). Finally, a similar observation was recorded on 27 July 2002, again in Cabbage Willows Bay, north of the Novide River (Hydro-Québec, unpublished data).

Breeding habitat in Cabbage Willows Bay is similar to that described elsewhere. In North Dakota, the Marbled Godwit shows a strong preference during breeding season for short, sparse to moderately dense cover along wetland shorelines and shorter vegetation in upland habitats (Ryan et al. 1984). In James Bay, Ontario, one nest was found in a raised, grassy ridge between two ponds, in an open coastal marsh (Peck and James 1983).

Estimated breeding chronology suggested that nest search was carried out in the egg-laying and early incubation period. This is consistent with the observed copulation (17 June 1991) and other previous records suggesting breeding (see above). The flight displays observed in 2003 also support the breeding chronology outline. Display behaviour is most frequent early in the breeding season and is commonly performed by

unpaired or nest-scraping males until incubation duties are initiated (Nowicki 1973). In Ontario, two breeding records from James Bay indicate that egg-laying was initiated approximately between 24 May and 31 May (Morrison et al. 1976; Peck and James 1983).

In 2003, the Marbled Godwit breeding population included at least four pairs in Cabbage Willows Bay. In 2002, the species was also recorded in Boatswain Bay, Jacob Island and Tent Island, between 23 July and 1 September (Hydro-Québec, unpublished data). However, considering the late dates and that no breeding behaviour was observed, it is likely that these birds were migrants rather than breeders. Although no Marbled Godwit was recorded during the aerial survey inland of Ministikawatin Peninsula, the species was located there in June 1990 and 1991, in three areas, including a bird on a shallow lake fen (Létourneau and Morrier 1996). In Ontario, the Marbled Godwit is also found up to 20 km inland (Gratto-Trevor 2000). Thus, the species probably breeds inland of Ministikawatin Peninsula. Its abundance there could exceed that of Cabbage Willows Bay because of the vast expanse of Tamarack fens. On 15 June 1991, 80 Marbled Godwits were counted in Cabbage Willows Bay (Létourneau and Morrier 1996). Their breeding status is questionable. As noted earlier, that date probably coincides with egg-laying and early incubation. Either these birds were on the point of dispersal for local breeding or were migrants on the way to northern James Bay breeding grounds in Ontario. However, if Marbled Godwits fly directly to breeding areas in spring from wintering sites on southeastern U.S. coasts, as the reverse is presumed to occur in the fall (Morrison et al. 1976), then those birds may have been local or regional breeders. Therefore, the Rupert Bay region probably holds a breeding population of between four pairs and a few dozens pairs.

Acknowledgments

This study was funded by Hydro-Québec. We are grateful to Françoise Lebrun and Gilles Lefebvre, from Hydro-Québec, for production of the map. We thank Jeffrey Salt, from the Waskaganish Cree community, for his contribution to this study. We are grateful to helicopter pilot Laurie Gagnon for her field assistance. Jean Doucet and Mary Antico provided helpful comments on an earlier draft of the manuscript. A. J. Erskine and an anonymous reviewer provided useful comments to improve the manuscript.

McGee, Brady K., Warren B. Ballard, and Kerry L. Nicholson. 2007. Swift Fox, *Vulpes velox*, den use patterns in northwestern Texas. Canadian Field-Naturalist 121(1): 71–75.

Predator avoidance may be a reason why Swift Foxes (*Vulpes velox*) are one of the most burrow-dependent canids in North America. Typically Swift Foxes have multiple dens, which they frequently move among. As part of a larger study to reduce Coyote (*Canis latrans*) related mortalities on Swift Foxes, we installed artificial escape dens in areas occupied by Swift Foxes on Rita Blanca National Grassland, Dallam County, Texas. For this paper, our objective was to determine the effects of artificial escape dens on Swift Fox den use patterns. From January 2002 to August 2004 we captured, radio-collared, and monitored 55 Swift Foxes. We documented annual number of dens used, rate of den use (fidelity), distance between dens, den area, and den sharing. We compared treated (artificial dens installed) and untreated (no artificial dens) areas but found no differences in annual number of dens ($P = 0.64$; $\bar{\chi} = 8$), rate of den use ($P = 0.96$; $\bar{\chi} = 35\%$), mean distance between dens ($P = 0.99$; $\bar{\chi} = 2{,}311$ m), den area ($P = 0.55$; $\bar{\chi} = 5.72$ km^2), or den sharing ($P = 0.46$; $\bar{\chi} = 42\%$ of time). We did not observe an effect of artificial escape dens on Swift Fox den use patterns probably because artificial escape dens were designed for temporary escape cover rather than diurnal den use.

Key Words: Swift fox, *Vulpes velox*, den range, den sharing, den use, fidelity, Texas.

Swift Foxes (*Vulpes velox*) were once abundant throughout the short and mid-grass prairies of North America but have rapidly declined with expansion of human settlement (Egoscue 1979). Studies have shown that the Swift Fox primarily inhabits areas of native rangeland (Allardyce and Sovada 2003). Much of the historical Swift Fox range has been fragmented into patches of native rangeland, Conservation Reserve Program, and agricultural fields (Allardyce and Sovada 2003). Habitat loss has been one of the reasons Swift Foxes were temporarily a candidate for endangered species listing with the United States Fish and Wildlife Service (USFWS) from 1992 to 2001 (USFWS 1995; USFWS 2001; Allardyce and Sovada 2003).

Predation has been another limiting factor on Swift Fox populations (Kamler et al. 2003a). Many studies have shown that Coyotes (*Canis latrans*) are the primary source of Swift Fox mortality, with annual survival rates ranging from 43 to 53% (Sovada et al. 1998; Kitchen et al. 1999; Matlack et al. 2000; Anderson et al. 2003; Allardyce and Sovada 2003). Because Coyotes rarely consume Swift Foxes they kill (Sovada et al. 1998; Kitchen et al. 1999; Allardyce and Sovada 2003), Coyote predation seems to be the result of both interference and exploitative competition (Kamler et al. 2003b).

Predator avoidance may be one reason why Swift Foxes are one of the most burrow-dependent canids in North America (Moehrenschlager et al. 2004). Dens are an integral part of Swift Fox ecology. Swift Foxes use dens year-round not only for protection from predators, but also for reproduction, resting, and avoidance of extreme climatic conditions (Egoscue 1979). In sparsely vegetated habitats occupied by Swift Foxes, dens may constitute crucial escape cover. Arjo et al. (2003) found the number of dens used by Kit Foxes (*Vulpes macrotis*) was positively correlated with Coyote numbers. In addition, White et al. (1994) suggested that Kit Foxes established a number of dens (≥20) to facilitate escape.

It has also been suggested that Swift Foxes move frequently among different den sites (Kilgore 1969; Hines and Case 1991), but little detail on den use patterns has been reported. Understanding Swift Fox den behavior may be an important factor in sustaining viable populations throughout their range.

Because Swift Foxes use dens year-round (Egoscue 1979), we installed artificial escape dens as part of a larger study to determine if lack of den sites limited Swift Fox populations in northwest Texas, USA (McGee 2005). The objective of this paper was to document the effects of artificial escape dens on Swift Fox den use patterns. We determined annual number of dens used, rate of den use (fidelity), distances between dens, den area, and den sharing. We predicted that with more dens available in treated areas Swift Foxes would use more dens, have less fidelity for certain dens, have greater distances between dens, and be less likely to share a den. We made comparisons between treated (artificial escape dens installed) and untreated (no artificial dens installed) areas.

Study Area

We collected data from a contiguous 100-km^2 area on the Rita Blanca National Grassland (NG) in Dallam County, Texas, approximately 43 km northwest of Dalhart, Texas (Figure 1). The NG consisted of native rangelands with short-grass prairie dominated by Blue Grama (*Bouteloua gracilis*), Side-oats Grama (*Bouteloua curtipendula*), Burrograss (*Haplopappus tenui-*

sectus), and Buffalograss (*Buchlöe dactyoides*) that were moderately to intensively grazed by cattle (*Bos taurus*; Kamler et al. 2003a,b; Nicholson 2004; McGee 2005).

Methods

We captured, handled, and radio-collared Swift Fox using methods described by McGee (2005). We tracked Swift Fox to their diurnal resting sites (dens) using a hand-held antenna 1–2 times per week. We recorded each den location with a Garmin global positioning system receiver (Garmin International Inc., Olathe, Kansas, USA). We only used Swift Fox that were monitored ≥8 months of the year in data analysis. We calculated annual estimates from September to August of each year for all analyses. This was to allow Swift Foxes an adjustment period after installation of artificial dens and to perform two full years of data analysis.

During April 2002, we placed 108 artificial escape dens in three spatially separated areas (Figure 1). We considered Swift Foxes belonging to a treated area if their home ranges overlapped an artificial escape den area by ≥50%. We considered untreated Swift Foxes as those whose home ranges did not overlap artificial escape den areas (McGee 2005). No Swift Foxes in untreated groups were ever located within an artificial escape den treated area. Also, we considered foxes to belong to the same family group if they used the same area and dens concurrently (Kitchen et al. 1999; Kamler et al. 2003a,b).

Escape dens consisted of corrugated plastic sewer pipes 4.04 m long, 20.32 cm diameter with 20.32 cm holes cut in the middle to allow foxes to modify and expand subterranean dens ($6.41/m U.S.; Amarillo Plumbing Supply, Inc., Amarillo, Texas, USA). The diameter size of our artificial escape dens was based on previous studies that reported a mean den opening height of 20.0 cm for Swift Fox dens (Cutter 1958; Hillman and Sharps 1978; Pruss 1999; Jackson and Choate 2000). Coyote dens were reported to be 30–37 cm in diameter (Bekoff 1977; Althoff 1980; Bekoff 1982; Harrison and Gilbert 1985). We assumed that artificial escape den entrances, being the same diameter as natural Swift Fox dens, were too narrow for Coyotes. A John Deere 260 skid loader (Deere and Company World Headquarters, Moline, Illinois, USA) was used to install and cover the sewer pipe with only the two open ends exposed. Escape cover was randomly oriented and spaced approximately 322 m apart in a 2.59 km^2 grid pattern for a density of 36/2.59 km^2 (McGee 2005).

We calculated rate of den use (fidelity) by dividing number of dens by the number of times the fox was located in dens (× 100%). Lower values represented higher den fidelity. We calculated distances between dens using Bearing and Distance Extension for ArcView 3.2 (Environmental Systems Research Institute, Redlands, California, USA). We used den locations to estimate annual den areas for Swift Foxes using 100% minimum convex polygon (MCP) method (Mohr 1947) as calculated by Home Range extension (Rodgers and Carr 1998) for ArcView 3.2 (Environmental Systems Research Institute, Redlands, California, USA). We calculated den sharing as percentage of time a radio-collared Swift Fox was found in a den with another radio-collared fox.

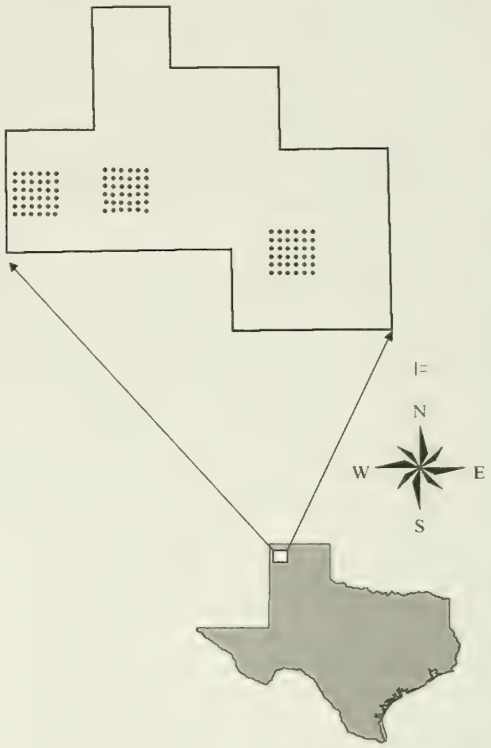

FIGURE 1. Map of the 100-km^2 study area located on the Rita Blanca National Grassland in northwest Dallam County, Texas, USA. One hundred and eight artificial escape dens (black dots) where installed in three separate grid locations.

We found no statistical differences among years so we pooled data to increase power. We used 1-way ANOVAs in SPSS 12.0 (SPSS 2003) to determine differences between treated and untreated areas for annual number of dens used, mean distances between dens, and mean den areas. We compared average rate of den use and sharing between treated and untreated areas using Yates' corrected chi-square tests (Zar 1999). Differences were deemed significant when $P < 0.05$.

Results

From January 2002 to August 2004, we captured and radio-collared 55 Swift Foxes (31 males, 24 females). We documented a total of 104 Swift Fox dens

Table 1. Average annual number of dens and den area of Swift Foxes on Rita Blanca National Grassland (NG) in northwest Texas, 2002–2004.

		Annual number of dens		Den range (km^2)	
Study area	n	$\bar{\chi} \pm$ SE	range	$\bar{\chi} \pm$ SE	range
treated	8	7.88 ± 0.48	6–10	6.34 ± 1.86	0.52–13.21
untreated	4	7.50 ± 0.50	7–9	4.50 ± 1.91	0.81–9.20

during our study including four separate occasions when we radio-tracked and observed Swift Foxes within artificial escape dens during the day. Due to the high turnover rate in our Swift Fox population, only 12 Swift Foxes (n = 8 treated, n = 4 untreated) were monitored for ≥8 months a year from September 2002 to August 2004.

There was no difference (P = 0.64) in annual number of dens used (mean ± SE) by Swift Foxes between treated (7.88 ± 0.48, n = 8) and untreated (7.50 ± 0.50, n = 4) areas (Table 1). Average rate of den use (fidelity) was similar (Yates' χ^2 = 0.003, P = 0.96) between treated (35.9%) and untreated (35.4%) areas. Mean distance between dens (± SE) was not different (F < 0.001, P = 0.99, 1-β = 0.05) between treated (2308 ± 442 m, n = 8) and untreated (2317 ± 654 m, n = 4) areas. There was no difference in den area (F = 0.38, P = 0.55, 1 − β = 0.09) between treated (6.34 ± 1.86 km^2, n = 8) and untreated areas (3.81 ± 1.91 km^2, n = 4). Den sharing only occurred between mated pairs. Average rate of den sharing was similar (Yates' χ^2 = 0.56, P = 0.46) between treated (44.9%) and untreated (39.0%) areas.

Discussion

We have shown that average number of dens used by Swift Fox each year was eight in northwest Texas (Table 1). Schauster et al. (2002) documented number of Swift Fox dens used was 2–8 for breeding and gestation season, 5–10 for pup-rearing season, and 3–8 for the dispersal season. Similar multiple den use has been documented with other small canids that share a dependence on dens, such as Artic Fox (*Alopex lagopus*; Eberhardt et al. 1983) and Kit Fox (Tannerfeldt et al. 2003; Moehrenschlager et al. 2004). Koopman et al. (1998) reported an average of 11.8 dens per year for Kit Foxes in California. Arjo et al. (2003) suggested to an increase in the number of dens used by Kit Foxes in western Utah could have been related to the increase in Coyote presence.

We found that Swift Foxes had relatively high fidelity to particular dens for both treated and untreated areas. Koopman et al. (1998) found that Kit Foxes exhibited a strong affinity for particular dens because Kit Foxes were located in their most frequently used den 32% of the time. Artic Foxes also preferred certain dens while others were used infrequently (Eberhardt et al. 1983). We suspect that den fidelity may be the result of den quality. Distinctions have been made between good and bad dens for Artic Foxes (Tannerfeldt et al. 2003). On the other hand, Swift Foxes frequently switch between dens (Egoscue 1979; Hines and Case 1991), suggesting poor den quality. One of the reasons for frequent changes between dens has been attributed to the large numbers of fleas found in Swift Foxes' dens (Kilgore 1969). Other factors like human disturbance, leaking, shifting towards food resources, and predator avoidance may play a role in Swift Foxes den switching and fidelity (Kilgore 1969; Tannerfeldt et al. 2003).

In addition, we documented a mean distance between dens of 2311 m (range 729–3998 m). Similarly, Moehrenschlager (2000) found that Swift Foxes in Canada moved to dens up to 1900 m away. In contrast, Cutter (1958) noted that Swift Fox dens in overgrazed pastures of northern Texas were concentrated but did not state the distance between dens. Cutter (1958) noted that up to six dens were frequently observed within 65 hectares of pastureland. Greater distances between dens would allow Swift Foxes access to more resources within their environment if dens were used to escape predators.

It has been suggested that carnivore home-range size can be affected by habitat composition and food distribution (Macdonald 1983). White and Ralls (1993) observed that larger Kit Fox home ranges were associated with low prey availability. We suspect that these effects can be applied to den area of Swift Foxes as well. Our results indicated a mean den area of 5.72 km^2. It is possible that Swift Foxes with larger den areas may have had greater access to food resources while avoiding predators. Ables (1969) recognized that Red Fox (*Vulpes vulpes*) home range size was affected by food abundance and availability. In addition, Hines and Case (1991) speculated that carrion availability and prey distribution probably affected Swift Fox home range size and shape. Likewise, Olson and Lindzey (2002) suggested that intensive hunting by Swift Foxes near natal dens may have reduced prey availability and consequently forced adults to expand the areas in which they hunted. Thus, larger den areas may be the result of fewer resources (Hines and Case 1991).

Although additional adult foxes have been observed with mated pairs at Swift Fox (Egoscue 1979; Covell 1992; Kitchen et al. 1999; Lemons et al. 2003), Arctic Fox (Eberhardt et al. 1983), and Kit Fox (Ralls et al. 2001; Tannerfeldt et al. 2003) den sites, we did not document this occurrence. Of the Swift Foxes that we monitored, only mated pairs were ever found occupy-

ing the same den. Adult radio-collared Swift Foxes in our study denned with their mate 39–44% of the time. Similarly, Koopman et al. (1998) found that mated adult Kit Foxes denned together about 45% of the time. Also, Ralls and White (2003) found that Kit Fox pair members shared the same den 51% of the time. It is possible that we underestimated the rate of den sharing. We believe that on occasion a radio-collared fox denned with adult foxes that were not radio-collared.

In conclusion, we were able to describe Swift Fox den use patterns in northwest Texas even though we did not observe an effect of artificial dens. One possible reason for not observing an effect may be the low sample sizes. Even though we captured 55 Swift Foxes during our study, residents were not abundant as data analysis was only performed on eight Swift Foxes in treated and four Swift Foxes in untreated areas that were monitored ≥8 months per year. Also, no observed effect of artificial dens may be due to the fact that artificial dens were designed for temporary escape from predators, specifically Coyotes, while Swift Foxes were away from their natural dens. As part of the larger study mentioned before (McGee 2005), we found higher annual Swift Fox survival ($P = 0.07$) in artificial den treated areas (0.81) than in untreated areas (0.52) on the same study site. Higher survival in treated areas suggests that Swift Foxes were using artificial dens for escape during their normal nocturnal activities. Diurnal use of artificial dens was limited. We only tracked Swift Foxes to artificial escape dens on four occasions during the day. Therefore, alternative artificial den designs need further study to find a more suitable diurnal artificial den for Swift Foxes.

Acknowledgments

Funding was provided by the National Fish and Wildlife Foundation and Texas Tech University. We thank the United States Forest Service personnel for letting us conduct research on the Rita Blanca National Grasslands and helping install artificial escape dens. We thank F. Pronger for allowing us to use his ranch as a study site. We also thank E. and B. Hampton for providing us with a place to stay while conducting field research. Research protocols were approved by the Animal Care and Use Committee at Texas Tech University. Flowering During January in Antigonish County, Nova Scotia*

David J. Garbary and Barry R. Taylor

Department of Biology, St. Francis Xavier University, Antigonish, Nova Scotia, B2G 2W5 Canada; e-mail: dgarbary@gmail.com
*Contribution from the Herbarium of St. Francis Xavier University

Garbary, David J., and Barry R. Taylor. 2007. Flowering during January in Antigonish County, Nova Scotia. Canadian Field-Naturalist 121(1): 76–80.

Over 85 records of 23 species of blooming, herbaceous angiosperms were made at 19 sites in Antigonish County between 7 and 21 January 2006, when daytime temperatures reached 15°C. These observations followed an unusually warm fall and early winter. All species were observed on waste ground or in fields and garden plots, except for *Epigaea repens* L. which was part of ground vegetation in a sparsely wooded site. The primary families represented were Asteraceae (six species), Brassicaceae (six species) and Carophyllaceae (four species). The most commonly observed plants were *Taraxacum officinale* (L.) Weber (11 sites), *Capsella bursa-pastoris* (L.) Medik. (nine sites), *Thlaspi arvense* L. (three sites) and *Stellaria media* (L.) Vill. (four sites). Many plants and inflorescences were conspicuously frost-damaged, and flowers were rarely fully open. In several species, e.g., *T. arvense* and *Cerastium vulgatum* L., many individual plants looked normal and there was no evidence of frost damage. These observations are the latest flowering records for Nova Scotia.

Key Words: Asteraceae, Brassicaceae, Caryophyllaceae, winter flowering, phenology, Antigonish County, Nova Scotia.

In Nova Scotia most species of flowering plants have ceased to flower by early November (Zinck 1998). Taylor and Garbary (2003) carried out an extensive survey of flowering during an unusually warm late fall in Antigonish County and found 92 species in bloom during November-December. These were the latest flowering records of all but one of these species, and extended the known flowering periods for plants in Nova Scotia by an average of 45 days. Of particular note were 15 species that were in bloom on 14-16 December 2001.

A detailed evaluation of the phenology of the entire late fall flora was again undertaken in 2005 after another warm fall in which abundant flowering was still occurring in early November. This study will be described elsewhere in the context of regional climate change (Garbary et al.). Here, we provide records of 23 species of herbaceous plants observed in flower during an extraordinary warm period in January 2006. Our observations complement those on spring phenology by Vasseur et al. (2001). They compared flowering times in 12 species in the late 1990s with dates a century earlier and showed significant changes in only two species, of which only *Syringa vulgaris* L. had earlier flowering.

Materials and Methods

Collection sites

Nineteen sites in Antigonish Town and County, northern Nova Scotia, were explored between 7 and 21 January 2006 in three collection periods. Adjacent sites were a minimum of 200 m apart, and the maximum distance between two sites was 23 km. Ten sites were visited on 7 January, 16 sites during the period 11-16 January, and seven sites on 21 January. Five sites were visited three times, and three other sites were visited twice. Most of these sites had been previously visited by Taylor and Garbary (2003). Sites were typically highly disturbed areas of waste ground or gravel (Figure 1), or agricultural fields or garden plots. Each site was surveyed for 15-45 minutes. Notes were taken on the flowering status and plant condition of each species in bloom. Representative plants were collected; plants with cryptic flowers were dissected and examined under a stereomicroscope to ensure that flowers were intact. Voucher specimens for most species were prepared and deposited at St. Francis Xavier University. Nomenclature follows Zinck (1998).

Weather

Weather data were taken from the nearest active Environment Canada meteorological station at Tracadie, approximately 25 km from Antigonish (http://climate.weatheroffice.ec.gc.ca/climateData/canada_e.html). The first collecting period was on 7 January when daytime temperatures reached 4.3°C. This followed several days with daily maximum temperatures above 0°C and daily minimal temperatures no lower than -2.5°C. Each of the succeeding four nights had frost, although daytime maxima were always above freezing. The second collecting period, between 12 to 16 January, had minimum and maximum temperatures of 0.4°C and 15.9°C, respectively. Temperatures between 15 to 20 January were cooler and frosts occurred most nights (minimum -6.8°C) although mean daily temperatures were below freezing on only one day (-4.6°C). The final collecting day was 21 January when temperature ranged from 2.0 to 8.4°C. This was followed by at least ten days when temperatures dropped below freezing (-0.3 to -9.2°C) and conditions were more typical of the season.

FIGURE 1. Sample habitat. Waste ground on campus of St. Francis Xavier University adjacent to Trans-Canada Highway. 7 January 2006. Four species were found in flower at this site.

Results

ASTERACEAE

Taraxacum officinale (L.) Weber was the most widely distributed species, occurring at ten sites. One to four plants were observed at each site during all three collecting periods and blossoms occurred at two sites on 21 January. Each plant had one or two ragged inflorescences with short pedicels. Leaves had some frost damage and were often flattened against the substratum, although they had good colour on some individuals.

Achillea millefolium L. occurred as a single plant in a farmer's field and as six plants on waste ground (Figure 2). Plants had green leaves, but the flowering shoots were often reclining, with several to dozens of white florets. The flowering shoots observed 14 January were wilted and most of the flowers had turned brown.

Two species of *Matricaria* were found: *M. maritima* L. and *M. matricarioides* (Less.) Porter. Plants of *M. maritima* were found at two sites. A single, well-developed inflorescence was found on 7 January as well as several partially intact flower heads. By 15 January remaining ray florets were mostly lost; however, the disc florets on many heads remained bright yellow. The plants were often partly wilted but the leaves had healthy colour. Up to three plants of *M. matricarioides* were found at each of three sites, and it was observed during the first two collecting periods. Inflorescences typically had a mixture of dull yellow and brownish florets. The plants appeared no less viable than others observed in early December.

Leontodon autumnalis L. occurred at two sites on 7 January where single individuals were found with only one or two wilted inflorescences on each plant. Basal rosettes had good colour but were slightly wilted. Examination of both sites one week later revealed no flowering individuals.

Two plants of *Senecio vulgaris* L. occurred at one site on waste ground; a single individual was found at a second site. Florets on most inflorescences had turned brown but several had bright yellow florets. Plants were a maximum of 10 cm in height and flowering was observed only in the first two observation periods.

FIGURE 2. *Achillea millefolium* photographed *in situ* on 7 January 2006 at site shown in Figure 1. Flowering shoot is about 30 cm tall.

BRASSICACEAE

Capsella bursa-pastoris (L.) Medik. was among the most common plants flowering in January. It occurred at nine sites with one to three plants per site. Flowering individuals were up to 30 cm tall and carried a few flowers at the apex of each plant. Leaves were typically green and healthy, although larger plants had generally become decumbent. During the second week, plants were mostly very small (5-10 cm high) with only a few florets. On 21 January flowers were found at two sites.

Thlaspi arvense L. was among the most robustly flowering species observed. The plants were erect, dark green and with prominent white flowers. *T. arvense* in flower was as common in January as in any previous collecting period, and flowers were found at one site on 21 January.

Raphanus raphanistrum L. occurred at two sites where there were typically many plants. The stems and leaves of these plants were badly wilted and reclining; however a few bright yellow florets and numerous clusters of buds remained intact at many apices on many plants. In the second week only a single, badly damaged plant was found at one site.

Cardamine pensylvanica Muhl. ex Willd. was the only species clearly protected by the heat shadow of a large building. Dozens of small, prostrate plants each with one to several flowers occurred in a flowerbed along the side of a large brick building. No decline in flowering was noted in the second week and flowers persisted to 21 January.

Erysimum cheiranthoides L. was found at two sites and only in the second week. Four large plants were found along a bare concrete foundation for a house. The surrounding lot supported numerous plants of this species but all had gone to seed. A second site had a few small individuals up to 5 cm tall. Both sites were covered with snow on 7 January and so were not examined until the second week.

A single plant of *Lepidium campestre* (L.) R. Br. was found 12 January on waste ground. The plant was about 20 cm tall and had two clusters of flowers with the most vigorous close to the ground and immersed in a cluster of leaves.

CARYOPHYLLACEAE

Stellaria media (L.) Vill. was found at two or three sites in all collecting periods (four sites overall), and was among the most prominent of the plants in flower. At two locations it was found as scattered individual plants; however, at two other sites it formed large expanses of continuous ground cover with numerous inflorescences (Figure 3).

FIGURE 3. *Stellaria media* photographed *in situ* on 7 January 2006 showing part of a large colony about 1 m in diameter.

Flowering individuals of *Cerastium vulgatum* L. were few and occurred at only three sites, although many vegetative plants or plants with remains of inflorescences were present at most locations. The reproductive individuals appeared healthy and showed no signs of frost damage. They grew on loose gravel where there was no competition from surrounding vegetation. Flowering persisted at one site to 21 January.

A few flowers were present on several plants of *Spergula arvensis* L. from a farmer's field in the first two weeks. The plants showed considerable frost damage and dissection showed that very few bore intact stamens and pistils. At a second site where vegetative parts of the plants were less damaged, no intact flowers occurred.

An extensive patch of *Spergularia rubra* (L.) J. & C. Presl. occurred on waste ground. The prostrate plants were 5-10 cm diameter and showed all reproductive stages from buds to fruits. The site was only examined during the second week of observation.

OTHER FAMILIES

Euphorbia helioscopa L. (Euphorbiaceae) was present at only one of the sites. There were hundreds of individuals. Large plants (20-40 cm tall) were con-

spicuously frost damaged, with the wilted stems causing the upper parts of the plants to topple over. The terminal portions of these plants looked healthy, and subsequent dissection of inflorescences showed intact flowers. Small plants (5-15 cm tall) showed less collapse of the stems and also had numerous intact flowers. Flowering persisted until 21 January.

Individual plants of *Fumaria officinalis* L. (Fumariaceae) were found on each of the first two visits to one site. The plants had two small inflorescences in which a few flowers still retained their characteristic two-toned colour. Inflorescences on other plants at this site had been severely damaged and turned brown. On most individuals the finely dissected leaves and delicate stems showed no conspicuous wilting. At another site dozens of plants grew in soil mounds, but there were no inflorescences.

Viola tricolor L. (Violaceae) occurred at two sites. Both were in flower beds and one was adjacent to a building. Plants at both sites had leaves and stems in excellent condition and several to dozens of fully open flowers with blossoms persisting until 21 January.

There were numerous plants of *Veronica persica* Poir. (Scrophulariaceae) at one site where they grew as prostrate clumps or straggling plants over the bare soil. The bilobed fruits were conspicuous, and a single intact but only partially open flower was found on single individuals returned to the laboratory at each of the three visits.

Vegetative plants of *Polygonum arenastrum* Jord. ex Boreau (Polygonaceae) were common at most sites. Although most plants had conspicuous frost damage, a few plants had two to three white-tipped buds and open flowers that persisted until week two.

Epigaea repens L. (Ericaceae) was the only woodland plant found in the study. An extensive population occurred at one site (14 January) among other ground vegetation beneath an open, mixed forest growing on sandy soil. Although buds on many plants appeared swollen, only a single plant had open blossoms.

Discussion

That any plants should be flowering in January in northern Nova Scotia, much less 23 species, is remarkable. This late phenology may reflect the ability of plants to have late flowering strains (e.g., *Thlaspi arvense*, Warwick et al. 2002), or possibly reflect a western European origin where fall and early winter temperatures would be much milder. Zinck (1998) does not include December in the flowering periods of any of these species; November is included in the flowering periods only for *Capsella bursa-pastoris*, *Matricaria matricarioides*, *Senecio vulgaris*, *Stellaria media* and *Viola tricolor*. The region falls within plant hardiness zone 5B of Agriculture and Agri-Food Canada (http://sis.agr.gc.ca/cansis/nsdb/climate/hardiness/intro.html), in which harsh winters kill non-hardy species.

January is normally associated with severe winter weather; the 30-year daily average temperature at Collegeville (the nearest meteorological station for which climate normals are available) is –6.6°C, and the average minimum is –11.6°C. Winters here are among the coldest in the province (Davis and Browne 1997). About 50 cm of snow falls on average in January, and a heavy snowpack is common. Snowpack depths in a wooded area of the St. Francis Xavier University campus were 40-50 cm in mid-January every year but one in 1999-2005 (B. Taylor, unpublished data). In the single low-snow year, the weather was very cold and the ground was frozen.

The circumstances that led to plants blossoming in mid-January were more complex than an extended period of warm weather. While fall and early winter of 2005-2006 were unusually mild, there had been regular nights of frost since November and two major snowfalls (5 and 15 December) prior to the collection period. The sites were visited over the course of three weekends, and in the intervening periods there were frosts on most night at Tracadie. These plant species appear to be very resistant to short-term freezing, as long as warm temperatures return quickly. In addition, the most severe weather may have occurred when the plants were covered with 20 cm of snow from the 15 December snowstorm. The snow would have insulated the plants from the deep frosts, but it was subsequently washed away by heavy rain.

None of the plants in bloom was restricted to the first round of collecting; indeed, five species were found in bloom only in the second round and ten species had blossoms on 21 January. The two sites supporting *Erysimum cheiranthoides* were snow-covered on 7 January and the single specimen of *Lepidium campestre* found in week two may have been missed on the earlier visit to the site. Only one site visited in this study could be considered highly protected and influenced by radiant heat from a building, and *Cardamine pensylvanica* was the only species unique to this site. The remaining sites were exposed to ambient air temperatures and precipitation.

Nevertheless, even though plants in bloom were found at 17 sites in mid-January, this was not a conspicuous phenomenon; surveys of additional sites revealed no plants in blossom. The sites with plants in flower comprised highly specialized habitats mostly of limited extent: land cleared for development, margins of abandoned or active agricultural fields, garden plots and soil mounds. Even within these sites, most plants of many species reported here had entirely succumbed to the rigours of winter.

The plant species in bloom were not a cross-section of the provincial flora. Most of the species reported here are opportunistic, weedy species that thrive in highly disturbed habitats, including agricultural settings (e.g., *Raphanus raphanistrum* L., Warwick and Francis 2005). Indeed many of our sites had less than 50% cover of vegetation. In addition, all species observed in flower except *Epigaea repens*, *Cardamine pensylvanica* and *Cerastium vulgatum* are non-native

members of the flora (Zinck 1998). Most of these species are weeds that were introduced from Europe with grain. It would appear that the ability to tolerate harsh physical conditions (in contrast with competitive ability) extends to tolerance of harsh weather as well (Taylor and Garbary 2003).

Flowering in January in a cold climate would appear to be futile, and therefore likely of little evolutionary value. Excepting *Epigaea repens*, all of the species reported here are annuals or short-lived perennials (Zinck 1998). As early colonizers of disturbed ground, they would be adapted to growing and reproducing quickly in advance of competition from later species. It seems likely that these species are adapted to grow, flower and set seed as long as the weather permits (e.g., *Senecio vulgaris*, Robinson et al. 2003). This phenology contrasts with that of longer-lived perennials in which above-ground plant parts senesce in late autumn in anticipation of winter. The ruderal species observed here evidently lack this adaptation, presumably because either cold temperatures (annuals) or competition (perennials) normally curtails reproduction and kills the plant. Consequently, when those events are delayed, the plants have no physiological mechanism to end flowering, even when seed production may be impossible.

An important exception to the above is Pomquet Beach Provincial Park, an undisturbed, coastal site where *Epigaea repens* was part of a dense community of ground vegetation beneath a diffuse tree layer. Unlike the remaining fall-flowering species, *Epigaea repens* normally flowers in April and May (Zinck 1998), when it forms a conspicuous part of the spring-flowering flora. The plants in flower in January may be considered either a second, late-fall flowering, or an exceptionally early spring flowering. This phenomenon contrasts with the situation of the remaining species, in which normal late-fall flowering merely persisted for a long time. It is doubtful that new flowers were initiated among these species.

Epigaea repens was observed in flower in the Annapolis Valley, about 250 km southwest of our study area, in early November 2005 (N. Nickerson, Agriculture and Agri-Food Canada, Kentville, personal communication). Hence our flowering material from Antigonish County probably should be considered a further extension of a late fall return to flowering. The same probably applies to *Fumaria officinalis*, for which the latest flowering month given by Zinck (1998) is August. It would be of interest to determine details of plant phenology for *E. repens* and other species at the extreme southern tip of the province, where January mean temperate is only just below freezing (plant hardiness zone 6B; Davis and Browne 1997).

Changes in plant phenology are indicators of climate change and have been used as a proxy for temperature (Badeck et al. 2005; Menzel 2002; Sherry et al. 2007; Walther 2004). Consequently, the January flowering records reported here might be considered as evidence of regional climate warming. Thus, even if regional climate warming has not been demonstrated, the changes that we observed would be a natural consequence of such a warming trend.

Acknowledgments

We thank Robert Garbary and Jonathan Ferrier who assisted with field work and Nancy Nickerson for information on flowering of *Epigaea repens*. This work was supported by grants from the Natural Sciences and Engineering Research Council of Canada to both authors.

Chubbs, Tony E., and J. Brazil. 2007. The occurrence of Muskoxen, *Ovibos moschatus* in Labrador. Canadian Field-Naturalist 121(1): 81–84.

Muskoxen were first observed in Labrador in 1988 and have since been recorded at several locations in two separate river valleys in northern Labrador. The occurrence of Muskoxen in Labrador is attributed to the dispersal of captive releases from Québec in 1973 and 1983. Here we document observation records and examine the future management of the species in Labrador and speculate on its possible effect on this northern ecosystem.

Key Words: Muskox, *Ovibos moschatus*, range, distribution, management, Labrador, Québec.

The Muskox (*Ovibos moschatus*) is a relic from the Pleistocene and is native to northern Canada, northwestern Greenland, and the northern coast of Alaska (Banfield 1974; Reynolds 1988). The elimination of the species from Alaska and the reduction of Muskox numbers in Canada by the early 1900s resulted in efforts to introduce and restore populations in several arctic areas (Klein 1988; Reynolds 1988). At present, Muskox populations are experiencing a period of success, with high numbers throughout most of their range (Groves 1997). Muskox apparently did not colonize the Québec-Labrador peninsula after the last glaciation as no remains have been found at archaeological sites (Banfield 1975).

In 1967, 15 Muskoxen (12 females, 3 males) were captured near Eureka, Ellesmere Island (Centre D'Études Nordique 1981*), and brought to the Umingmaqautik farm, near Kuujjuaq in northern Québec (Figure 1) for Inuit to establish a Muskox farm, create employment, and build up a stock to introduce the species into northern Québec (Le Hénaff and Crête 1989; Nault et al. 1993). A project of raising the animals to collect their quviut (Muskox wool) was unsuccessful. Subsequently, from 1973 to 1983, 54 animals were released at three different locations in northern Québec (Le Hénaff and Crête 1989). The first release sites were located to the north of Kuujjuaq and to the southwest of Tasiujaq (Le Hénaff and Crête 1989). In 1983, Muskoxen were released east of Kuujjuaq near the outlet of the Whale River. The Umingmaqautik farm was closed in 1983 and the remaining animals were given to the St-Félicien and the Orsainville zoos in Québec (Jean and Rivard 2005*).

The introductions in Québec proved successful. In 1983 a total of 148 Muskoxen were counted and by 1986, with a finite rate of increase of 1.25, the population had increased to 290 animals. By 1986, individuals and mixed groups of Muskoxen had dispersed in all cardinal directions up to 650 km from the original release sites throughout the province of Québec (Le Hénaff and Crête 1989).

In 2003, the Muskox population around Kuujjuaq and Tasiujaq was estimated to be 1400 animals, including calves (Jean and Rivard 2005*). In June 2005, aerial surveys on Diana Island, near Quaqtaq, counted a total of 112 adults and 25 calves. This new population apparently originated from the Tasiujaq area (Jean and Rivard 2005*).

Study Area

Over the past two decades, Muskoxen have been observed on several occasions in the Low Arctic Alpine-Torngat ecoregion in northern Labrador. This ecoregion has short, cool summers and long, cold winters with mean average daily temperatures ranging from -19 to -22°C in February and 7 to 9°C in July. Average annual precipitation is 500 to 700 mm with a total average snowfall of 3 m (Meades 1990*). The vegetation is tundra (Alpine heath) with sedge meadows dominating plateaus and Mountain Alder (*Alnus crispa*) and willow (*Salix* spp.) thickets dominating on the lower slopes and river valley slopes. Groves of White Birch (*Betula papyrifera*) and Balsam Poplar (*Populus balsamifera*) occur sporadically in some river valleys. Graminoids occur on the valley bottoms but are sparse to absent on the upper slopes and at high elevations. Dwarf Birch (*B. glandulosa*), Labrador Tea (*Ledum groenlandicum*) and Black Crowberry (*Empetrum nigrum*) dominate drier mountain ridges. Conifer trees are absent from this region (Meades 1990*). Major features of the terrain include braided east-flowing rivers, foothills, elevated plateaus, rugged coastal cliffs and inland mountains.

Methods

We recorded Muskox sightings during remote aerial field surveys in northern Labrador. We queried residents from remote communities throughout northern

Labrador and helicopter and fixed-wing aircraft pilots for sightings of Muskoxen. We found only one record of Muskoxen in other areas of Labrador apart from our own observations. We classified individual Muskox to age and sex from oblique aerial photographs. When possible, animals were classified as adult male or female, based on body size, coat color and size and shape of horns.

Observations

Five sightings of Muskoxen have been recorded in Labrador over the past two decades in three different river valleys, approximately 340 km apart. Four sightings were made from a helicopter in different years (1988, 1995, 2000, 2005) and included three sightings of a single Muskox, likely different animals, and one sighting of a group of three. The fifth sighting (2006 – 2008) was reported by residents of Nain while travelling by snowmobile to Voisey's Bay.

Site 1. Komaktorvik River Valley

The first sighting of Muskoxen in Labrador was recorded on 24 July 1988 at approximately 59°14'N, 63°56'W along the Komaktorvik River valley, which flows into Seven Islands Bay (Figure 1). Three individuals were observed in a large patch of willows (*Salix* spp.) in the river valley. All individuals had horns with a slight separation in the butte and were all approximately the same size indicating that these animals were likely adult males, although definite sex and age remain uncertain (J. Brazil, personal observation).

On 28 July 1995, one Muskox was again observed in the Komaktorvik River valley (59°14.65'N, 63°55.51'W) very near the original 1988 sighting. From a photograph, this animal, browsing in a large thicket of willows (*Salix* spp.) along the north slope of the river valley, appeared to be an adult male.

On 30 July 2000, during aerial surveys for Harlequin Ducks (*Histrionicus histrionicus*) and Peregrine Falcons (*Falco peregrinus*), we observed and photographed a lone Muskox in Seven Islands Bay at (59°14.16'N, 63°57.66'W) 3 to 4 km west of the previous sightings in 1988 and 1995. This animal was large, had well formed horns, and light coloration on the back and saddle and was identified as a sub-adult male (Olesen and Thing 1989).

The sightings along the Komaktorvik River valley occurred approximately 250 km northeast of the release site at Whale River providing a straight-line rate of dispersion of 50 km/year. The most probable dispersion route was along the Koroc River valley, which traverses the Labrador Peninsula.

Site 2. Hebron Fiord

On 9 June 2004, a single Muskox was observed near the outlet of Hebron Fiord (58°03.82'N, 63°12.71'W) (Figure 1, Site 2). This animal was feeding in a thicket of alders (*Alnus* spp.) and Willows (*Salix* spp.) at the foot of a small plateau on the north side of Hebron Brook where it flows into Hebron Fiord. A photograph identified this animal as an adult male > 4 years old (D. Jean, personal communication). The straight-line dispersal from the Whale River release site was a distance of 220 km providing a rate of dispersion of approximately 11 km/year. The most probable route of dispersion was south along the George River valley and then the Tasirlaq River to Hebron Fiord.

Site 3. Voisey's Bay

In April 2006, the fifth Muskox reported in Labrador was observed on a small unnamed island south of Tabor Island in Voisey's Bay at approximately 54°20'N, 61°43'W (Figure 1, Site 3). This animal was readily identifiable as its right horn tip was broken at the curl. This 4-5 year old male has remained on the island and is in its second winter at this location. The straight-line dispersal from the Whale River release site is a distance of 400 km providing a rate of dispersion of approximately 17 km/year. The most probable route of dispersion was south along the George River valley and then along either the Fraser or Kogaluk river to Voisey's Bay.

Discussion

Muskoxen have successfully dispersed and colonized many remote regions of northern Québec. The dispersal of Muskoxen from Québec into Labrador may have been influenced by unoccupied habitat and lack of dispersal barriers.

No mixed-aged groups (the reproductive segment of the population) have been observed to date in Labrador. It is thus likely that the separate observations at Komaktorvik River valley, Hebron Fiord and Voisey's Bay are of different animals that immigrated to Labrador through separate overland routes and at different times. Based on the dispersion of Muskox south along the George River in Québec through 1986 (Le Hénaff and Crête 1989), it is possible that other individuals or groups have traveled eastward into Labrador as far south as Nain along the numerous river valleys extending inland.

Although Muskoxen and Caribou (*Rangifer tarandus*) are occasionally found together on the same vegetation type, caribou usually move through an area rapidly, feeding on willows and flowering forbs whereas Muskoxen are more sedentary and forage on sedges and grasses (Parker 1978). Abundance and distribution of Muskoxen on many of the islands of the High Arctic appear to be related to the abundance and distribution of sedge-producing meadows (Parker et al. 1975; Parker and Ross 1976).

Initial colonization by Muskox may be slow and sporadic consisting mainly of adult males (Le Hénaff and Crête 1989; Reynolds 1988). This may explain why reproductive, mixed-aged groups have do not appear to have been observed yet in Labrador. As Muskoxen had populated many remote regions of Québec in all cardinal directions north of 54°30'N latitude by 1986 (Le Hénaff and Crête 1989) and populations continue

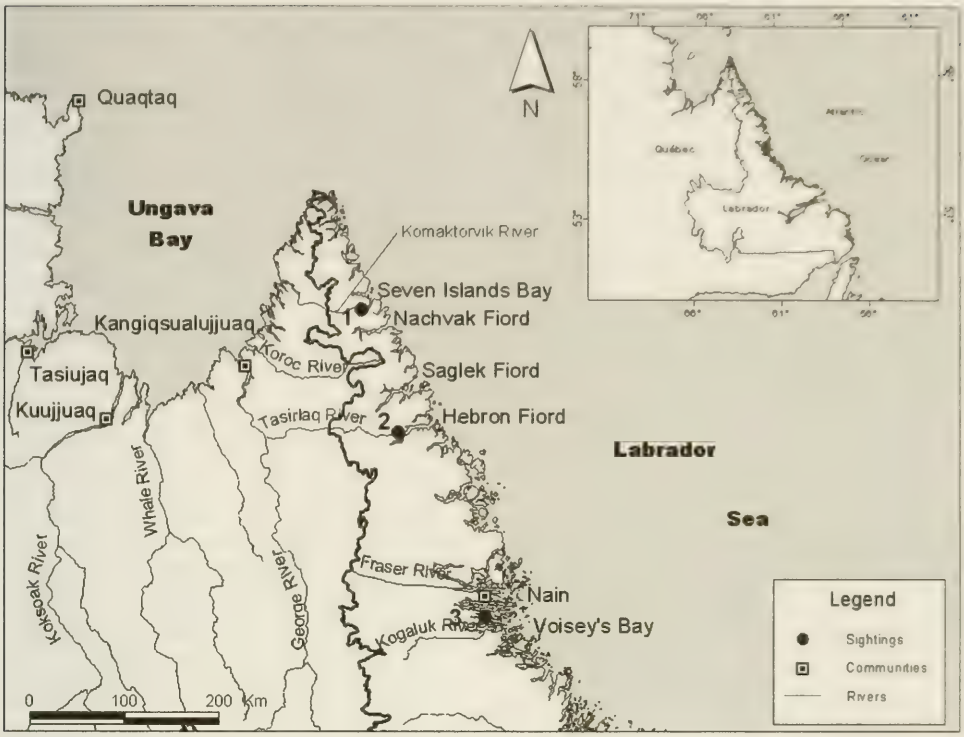

FIGURE 1. Location of Muskox (*Ovibos moschatus*) sightings in northern Labrador. The two release sites were near Tasiujaq and Kujjuaq in Québec.

to grow (lambda = 1.25) near their maximum finite rate of increase (1.30), breeding groups may have become established in Labrador but have gone undetected. Emigration of mixed-sexed groups out of regions first occupied may result in shifts in population distribution and range expansion (Reynolds 1988). The dispersal and colonization of Muskoxen to adjacent ranges can be slow. However, with the present high rate of population increase (Jean et al. 2004*) in northern Québec, we believe that emigration may soon result in a shift in an expansion of the distribution and range of Muskoxen into Labrador. Reynolds (1988) identified three stages in the expansion of Muskox into new range: (1) slow growth following release (2) the irruptive phase and (3) decline and stabilization. It is likely that in the next decade during the decline and stabilization of Muskox numbers in Québec that the dispersal of mixed groups into Labrador will occur and a breeding population be established.

In Alaska, where Muskoxen were extirpated and later reintroduced, range expansion occurred only over 20% of the former Muskox range and populations grew to fewer than 1000 individuals over nearly 30 years (Reynolds 1988).

Management Implications

Hunting of Muskox under a limited permit system is conducted on Nunivak and Nelson islands and in the Arctic National Wildlife Refuge of Alaska and in Nunavut, Northwest Territories, and Québec in Canada. Muskoxen are considered a unique and valuable trophy by the outfitting industry and Muskox meat is highly valued as an exported delicacy. This survivor of the ice ages is an important attraction for tourists, photographers, researchers and students of wildlife in areas where the species is endemic or introduced.

The establishment of a Muskox population in Labrador may provide an alternative to Caribou as a source of protein for northern communities as well as a new resource for developing the regional economy through sport hunting similar to northern Québec and Alaska (Le Hénaff and Crête 1989; Jean et al. 2004*; Reynolds 1988).

It appears that habitat for Muskoxen is widely distributed and largely unchanged in northern Labrador. With public support and proper management, Muskoxen may eventually become a more visible and familiar wildlife species in Labrador. We recommend that systematic aerial surveys be conducted to document the current and future status and distribution of Muskoxen in Labrador.

Acknowledgments

Thanks are extended to D. Jean, Ministère des Ressources naturelles et de la Faune, who provided literature on Muskoxen introduction and releases in Québec

as well as assistance in sexing and aging Muskoxen from photographs. M. Crête, F. Phillips, G. Parker, the late N. P. P. Simon and an anonymous reviewer provided comments on earlier drafts of the manuscript. L. Elson drafted the figure. The Department of Environment and Conservation, Government of Newfoundland and Labrador, provided funding for this publication.

The Spindle Tree, *Euonymus europaea* L. (Celastraceae): A Newly Naturalized Shrub in Nova Scotia

David J. Garbary[1] and Amy E. Deveau

[1]Department of Biology, St. Francis Xavier University, Antigonish, Nova Scotia B2G 2W5 Canada; e-mail: dgarbary@gmail.com

Garbary, David J., and Amy E. Deveau. 2007. The Spindle Tree, *Euonymus europaea* L. (Celastraceae): a newly naturalized shrub in Nova Scotia. Canadian Field-Naturalist 121(1): 85-88.

Over 100 plants, including over 750 individual shoots, of *Euonymus europaea* L. are reported from the Town of Antigonish in northern Nova Scotia. Plants were found in five discrete areas separated by 200-1000 m. A few individuals at one site may represent human planting; however, over 90 % of plants occur on waste ground or in dense shrubbery where natural colonization has occurred. Many individuals were observed in fruit in the fall of 2005, and over 95% of the plants had well developed buds and flowers in May and early June 2006. *Euonymus europaea* is considered a newly naturalized species for the flora of Nova Scotia.

Key Words: Spindle Tree, *Euonymus europaea*, introductions, naturalized, Nova Scotia.

Euonymus (Celastraceae) is a cosmopolitan genus of over 200 species of vines, deciduous and evergreen shrubs, and small trees (Gleason and Cronquist 1991). Many species are ornamentals because of their colourful fruits and fall foliage and their unusual winged stems. At least six species are recorded from Canada, of which one is regarded as doubtful (Scoggan 1978; Catling 1997; Hinds 2000). Only *E. occidentalis* Nutt. ex Torr. (Western Wahoo), *E. atropurpurea* Jacq. (Eastern Wahoo) and *E. obovata* Nutt. (Running Strawberry-Bush) are native in Canada, with *E. occidentalis* restricted to the west coast. *Euonymus europaea* L., *E. fortunei* (Turcz.) Hand.-Mazz., *E. alata* (Thun.) Siebold, and *E. nana* Bieb. are escapes from cultivation in eastern Canada, although they have restricted distributions in New Brunswick (Catling 1997; Hinds 2000). Other species occur in the northeastern United States (i.e., *E. alata* and *E. americana* L., Gleason and Cronquist 1991). No species is included in the flora of Nova Scotia (Zinck 1998).

Euonymus europaea was first noted in Antigonish as a single, non-cultivated plant in 2001 in Antigonish County, Nova Scotia (DJG unpublished). In a subsequent survey during fall and early winter of 2005-2006 (Garbary and Taylor 2007), fruiting plants of *E. europaea* were noted from the previously recognized site as well as additional sites in Antigonish. The species likely represents an escape from cultivation. Here we report *E. europaea* as a newly naturalized plant in Nova Scotia.

Materials and Methods

During the course of plant surveys in late fall and early winter of 2001 and 2005-06 (Taylor and Garbary 2003; Garbary and Taylor 2007), fruiting specimens of *Euonymus europaea* were noted. In May 2006, when flower buds were well developed but unopened, a survey of all previously identified locations was undertaken. Further surveys were conducted to determine the size of the overall population in Antigonish and the extent to which the species was reproducing. The four primary sites are designated as University, Claymore, Hospital, and Brierly Brook (see Table 1). Two additional sites with only 1-2 primary plants were found but are not included in Table 1.

Sites were surveyed with hand-held GPS units (Garmin 12, Olathe, Kansas, USA). The largest stem in any cluster was considered the primary plant, and adjacent shoots were assumed to be derived from the same base, or progeny from seed. The height of the largest plant at each site was measured with a meter stick, and the numbers of subsidiary shoots and nearby juveniles were counted. These data were gathered to demonstrate that plants were successfully reproducing in the area. For each primary plant, the slope, exposure to full sunlight, proximity to water (ditches, ponds or saturated soil) and reproductive condition were recorded. The number of flower buds on each peduncle was counted on the population on St. Francis Xavier University. Voucher specimens are deposited in the herbarium of St. Francis Xavier University (STFX) with duplicates deposited in herbariums of ACAD (Acadia University) and NSPM (Nova Scotia Provincial Museum).

Results

With its opposite leaves on short petioles, the longitudinal whitish markings on many young stems that often gives them a four-angled outline, and the brilliant scarlet and orange fruits, *Euonymus europaea* is a distinctive species during all seasons (Figure 1).

Most primary shoots (> 95%) and many adjacent smaller plants had abundant clusters of flower buds in mid- to late May 2006. The bud scales of branch buds and developing inflorescences had red tips and a ciliate

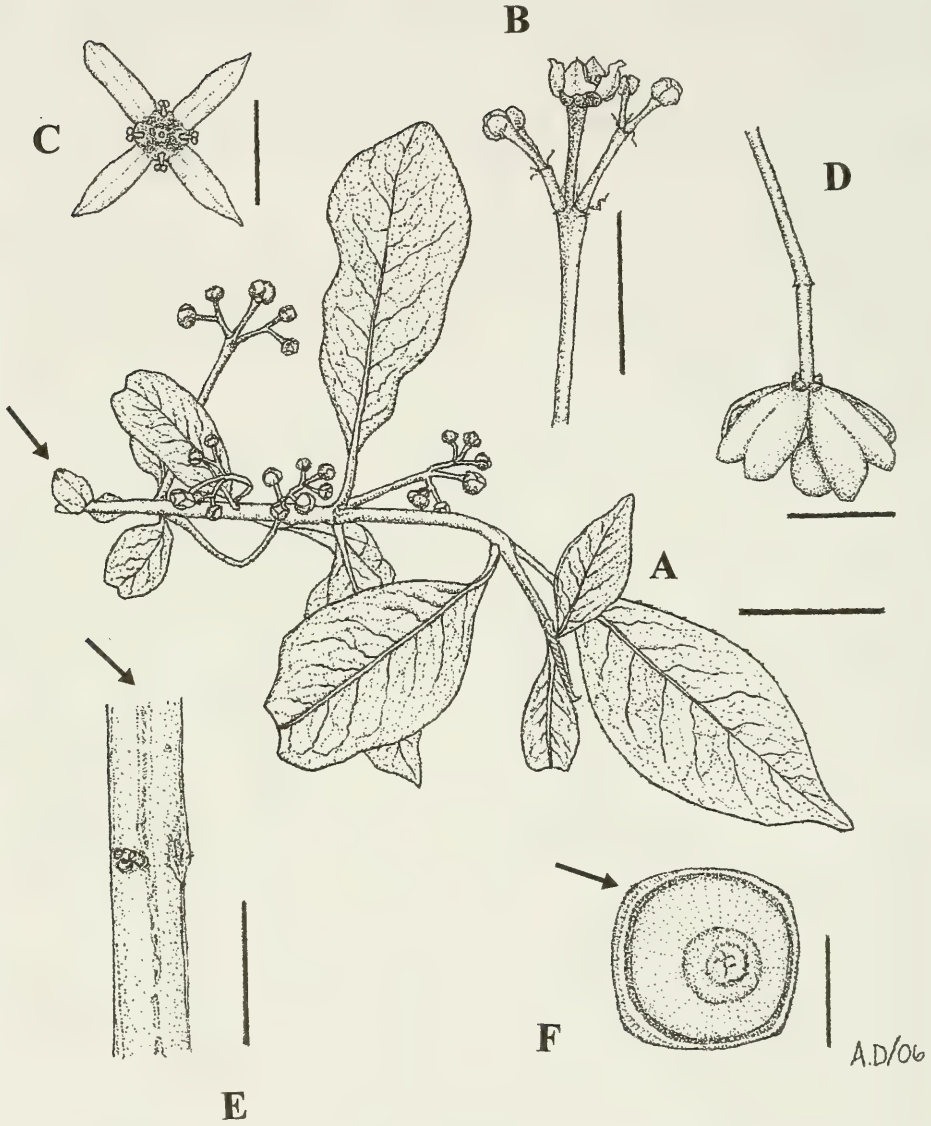

FIGURE 1. *Euonymus europaea* from Antigonish. A) Branch with leaves, developing inflorescences and bud scale (arrow). Scale = 2 cm. B) Inflorescence with central bud partially open. Scale = 1 cm. C) Fully open flower. Scale = 5 mm. D) Mature fruit after dehiscence showing single seed. Scale = 1 cm. E) Longitudinal view of stem showing leaf scar and longitudinal ridge on bark (arrow). Scale = 2 cm. F) Transverse section of stem showing squarish outline and position of longitudinal ridges. Scale = 5 mm.

margin. Flowers did not open until late May when a single bud in each peduncle opened. The flowers are not conspicuous, and plants are cryptic against a background of the larger and showier species of *Prunus*, *Crataegus* and *Amelanchier*. The flowers are ca. 1 cm diameter, and have diagnostic greenish-white petals. The flowering peduncles had from 1-9 buds (5.0 ± 1.8), with most inflorescences having odd numbers of buds.

Over 100 primary plants over 50 cm high and over 650 secondary shoots and adjacent progeny were found at six locations in Antigonish (Table 1). The primary axes were 1.5 ± 0.8 m (mean ± s.d.) tall, and many plants were over 3 m (Figure 2) with a trunk diameter of up to 6 cm. There was wide variation (0 – >50) in number of secondary shoots and progeny associated with each primary plant, although about 30% had

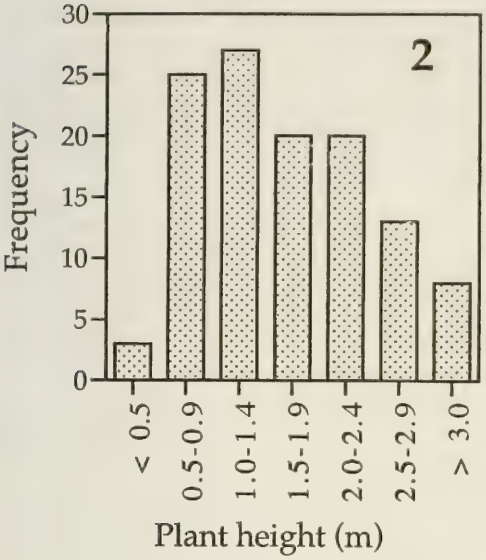

FIGURE 2. Histogram showing sizes of 112 primary stems of *Euonymus europaea* from Antigonish.

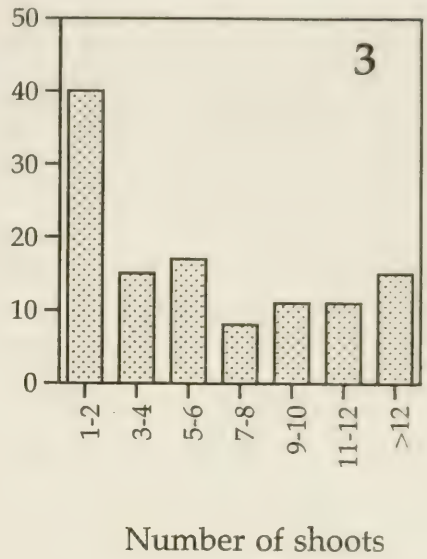

FIGURE 3. Histogram showing number of secondary shoots and possible progeny associated with each primary plant.

only 1-2 additional axes (Figure 3). The largest single clump was at the Brierly Brook site. It occupied about 4 × 3 m and had about 50 separate stems that formed a dense thicket.

Plants were typically found in the open where they experienced full sun, or at the edges of dense shrub thickets where they were either crowded or overtopped by the surrounding plants. Most plants grew in moist locations. Plants in the open tended to occur on boggy ground, and plants were common close to ditches, ponds or small pools or on the flood plain of a stream. Some plants were present on steep slopes on ground with obvious seeps. Only a few plants occurred on drier soils; these were in grass on mowed areas and may have been planted.

Discussion

All of the *Euonymus* plants we observed were *E. europaea*. The plants are scattered over several square kilometres in at least five separate sites. The abundance of small plants within 3 m of larger individuals and widely scattered small plants (i.e., less than 1 m) show that successful seed germination is occurring. These observations are consistent with the definition of naturalized of Pysek et al. (2004); i.e., that successful reproduction has been occurring for at least ten years in the vicinity of the parent plant.

The site where most of the plants were found is an open field where *E. europaea* is mixed with many other shrubs. These shrubs are mostly widely scattered and

TABLE 1. Populations of *Euonymus europaea* in Antigonish. Additional sites with only one or two primary plants not included in the table.

	Hospital	Claymore	Brierly Brook	University
Latitude and longitude	45°37.743'N 61°59.033'W	45°37.056'N 61°58.877'W	45°37.394'N 61°59.179'W	45°37.074'N 61°59.182'W
Number of primary plants	12	4	5	90
Secondary shoots and juveniles	61	11	95	683

Habitats	Steep slope with extensive bed of lupins; mowed and unmowed grassy area	Shrub thicket beside small stream	Border of hayfield at margin of thicket adjoining stream	Open areas with herbaceous plants and shrubs; on flat ground to steep slopes
Shade	Full sun	Partial to heavy shade	Partial to high shade	Full sun but some heavily shaded

have an overall cover of less that 15%. The occasional individuals that we observed in dense shrubbery had few secondary shoots. Thus, once vegetation closes in, *E. europaea* may not be able to establish or spread. Species with fleshy fruits have low ability to recruit under a canopy of *E. europaea* relative to nine other tall shrub species (Kollmann and Grubb 1999). This has not yet become important in Antigonish, since we have observed only one continuous canopy of *E. europaea.*

Some *Euonymus* species, including *E. alata,* have become invasive in several northeastern and midwestern states (e.g., http://tncweeds.ucdavis.edu/alert/alrteuon.html) following escape from ornamental plantings. *E. alata* is considered a threat in woodland areas, fields and coastal scrubland, where it can outcompete native species. There is no record of *E. europaea* as a problematic invasive species, although it has become widely naturalized in central Canada. Montgomery (1957) refers to sites where it has become "very common" in woods. The abundance of mature and immature individuals in Antigonish suggests that this is possible for *E. europaea* in Nova Scotia. The extensive field survey carried out by DJG in the fall and early winter of 2005-2006 identified four of the sites reported here. Additional surveys in 2006-2007 did not reveal further populations. While there are no specimens based on wild collections of *E. europaea* in other local herbaria (i.e., NSPM, ACAD, NSAC [Nova Scotia Agriculture Canada]), other urban areas may be expected to host wild plants (e.g., Wolfville, Nova Scotia – Sam Vander Kloet, personal communication). To satisfy the Pysek et al. (2004) definition of invasive, many offspring must be produced at a distance from the parent individuals. The limited dispersal of *E. europaeus* in Antigonish has not yet satisfied this criterion.

Acknowledgments

We thank Greg Power, Kelly Clement and Meghan Hines for assistance with fieldwork, Randy Lauff who pointed out the location of an additional *Euonymus* site, and Barry Taylor for comments on the manuscript. Curators of ACAD, NSPM and NSAC provided information and access to collections. This research was supported by research grants from the Natural Sciences and Engineering Research Council of Canada to DJG.

Notes

Serviceberry, *Amelanchier intermedia*, Escaped from Cultivation in Eastern Ontario

Paul M. Catling and Gisele Mitrow

Agriculture and Agri-Food Canada, Environmental Health, Biodiversity, Saunders Building, Central Experimental Farm, Ottawa, Ontario K1A 0C6 Canada; e-mail: catlingp@agr.gc.ca

Catling, Paul M., and Gisele Mitrow. 2007. Serviceberry, *Amelanchier intermedia*, escaped from cultivation in eastern Ontario. Canadian Field-Naturalist 121(1): 89–91.

Although not generally recognized as a cultivated plant, *Amelanchier intermedia* is widely cultivated in eastern Ontario under the incorrect name, *A. canadensis*. Wild plants referable to *A. intermedia* in old fields south of Ottawa are likely to be escaped from cultivation. *Amelanchier intermedia* likely originated as a hybrid involving *A. canadensis* and *A. laevis*. A key to the Canadian species of *Amelanchier* with glabrous ovaries is provided.

Key Words: Saskatoon, Juneberry, Serviceberry, Shadbush, *Amelanchier intermedia*, status, cultivation, hybrid, Ontario.

Fernald (1950) and Kartesz and Meachum (1999) reported *Amelanchier intermedia* Spach from Newfoundland to Minnesota and south to North Carolina. It was not included in Michigan by Voss (1985), but Cinq-Mars (1971) showed a relatively extensive distribution in southern Quebec. Although within the general range outlined by Fernald (1950) and frequent in adjacent Quebec (Cinq-Mars 1971), *A. intermedia* was not reported in Ontario by Soper and Heimburger (1982) or McKay (1973). Although it was listed for Ontario by Newmaster et al. (1998*), the listing was without ranking indicating a lack of information on its status. Over several years of examining populations of *Amelanchier* in Ontario we have found plants that correspond to the description of *A. intermedia* at only two locations in old field habitats south of Ottawa. Plants similar to these wild plants are widely cultivated but are never called *A. intermedia*.

Most eastern Ontario nurseries offering shrubs for sale offer Serviceberry (also called Juneberry, Shadbush and Saskatoon, *Amelanchier* spp.). The plants that are most frequently available are either multi-stemmed shrubs labelled as *A. canadensis* or they are named cultivars referable to *A.* ×*grandiflora* Rehder, a hybrid of *A. arborea* (Michx. f.) Fern. and *A. laevis* Wieg. The plants referred to as *Amelanchier canadensis* (L.) Medic. are particularly popular with companies providing landscaping for office buildings, whereas the larger small trees are increasingly popular for use as street trees under utility wires (Gerhold 1999).

Identification of wild and similar cultivated plants

With petals 9–13 mm long and reddish-tinged leaves prominently acute at the tip, the plants growing in old fields and woodland edges south of Ottawa (cited below) and similar plants labelled as *A. canadensis* in 10 local nurseries as well as many plants in Ottawa gardens could not be placed with *A. canadensis*, which has petals 3–10 mm long and green young leaves with leaf tips more or less rounded (Cruise 1964; Cinq-Mars 1971). They are not *A. laevis* because the leaves are tomentose at flowering instead of glabrous. Nor are they *A. arborea* because these are multi-branched shrubs with reddish-tinged leaves and flowers with a relatively broad hypanthium 4.5–5.5 mm across instead of single-trunked trees with green leaves and flowers with a relatively narrow hypanthium 2.5–3 mm across. They also differ from *A. arborea* in having sepals that are less reflexed and lanceolate with a concave outer edge instead of strongly reflexed at the base and oblong-lanceolate with the outer edge convex. In addition the berries of these shrubs are pleasant-tasting rather than insipid as in *A. arborea*. These plants do correspond to *A. intermedia* Spach of Fernald (1950) and Cinq-Mars (1971).

While it is clear that *A. intermedia* occurs both as a cultivated plant and outside of cultivation in eastern Ontario, it is not clear whether or not the wild plants are escapes from cultivation. It seems most likely that they are escaped since one of the parents, *A. canadensis*, does not occur in the local area and the similar widely cultivated plants have become increasingly popular over the past few decades and are currently widely available in nurseries and widely used by landscaping companies. A key to the group with glabrous ovaries is provided below.

Specimens referable to *A. intermedia* growing outside of cultivation in Ontario include: Ottawa-Carleton: open, sandy ground 3 km N of Herbert's Cor-

ners, Osgoode Twp., 45.2359°N, 75.5733°W, 17 May 2002, *P. M. Catling s. n.* (DAO); UNITED COUNTIES OF STORMONT, DUNDAS AND GLENGARRY: open old field, 2 km WNW of Ormond and about 5 km N of Winchester at 45.1552°N, 75.4173°W, 21 May 2005, *P. M. Catling 2005-41, 2005-42* (DAO). Cultivated specimens referable to *A. intermedia* collected as part of this study in Ottawa area gardens are also preserved in DAO (see DAO 798819, 801264, 801265, 801272, 801275, 801280, 801328, 801329, 801330, 801332) and vouchers obtained from nurseries are also in the collection (see DAO 800923, 800924, 800925, 801262, 801267, 801269, 801270, 801271, 801333, 801335).

Taxonomic history and possible hybrid origin of *A. intermedia*

Jones (1946) included the name *intermedia* with his relatively narrowly defined *A. canadensis* showing a largely eastern coastal plain distribution. Wiegand (1920) used the name to represent a species related to *A. canadensis* which he defined narrowly. Later Fernald (1950) expanded the concept to include plants clearly intermediate between *A. canadensis* and *A. laevis* and this concept was maintained in the classic work of Cinq-Mars (1971).

Amelanchier intermedia may have arisen as a hybrid of *A. canadensis* and *A. laevis* as noted by various authors (e.g., Gleason and Cronquist 1991). Plants referable to *A. intermedia* have leaves that are only moderately pubescent and losing their pubescence at flowering. This and their purplish tinge suggests that one parent is a species with leaves purple-green and glabrous and unfolded at flowering. The only species with a glabrous ovary fitting this description is *A. laevis*. The relatively short petal lengths and also the widely open hypanthium of the putative hybrids suggest that the other parent may have short petals, barely reflexed sepals and a saucer-shaped hypanthium. This is true of *A. canadensis* but not *A. arborea* which has relatively long petals, prominently reflexed sepals and a rather narrow, campanulate hypanthium. Furthermore a cross of *A. arborea* and *A. laevis* would be expected to produce a more tree-like hybrid, one form of which, *A.* ×*grandiflora* Rehd. is well known. Other species of *Amelanchier* have pubescent ovary summits and/or rounded and more coarsely toothed leaves and are thus excluded from consideration as putative parents. *Amelanchier canadensis* × *laevis* hybrids have been reported to be common in some areas, whereas hybrids of *A. arborea* and *A. canadensis* are less common (Cruise 1964).

The only material that can be confused with *Amelanchier interior* that occurs in the lower Ottawa valley are depauperate specimens of *A. arborea* which differ in their early flowering with unexpanded and very hairy leaves and apparent hybrids of *A. laevis* and *A.spicata* which differ in their broad spatulate petals and partially hairy ovaries. The typical habitat of these latter plants is dried and disturbed heath bogs where *A. spicata* also occurs. Such plants may have been the basis for reports of *A. intermedia* from edges of bogs in Minnesota (Nielsen 1939). Alternatively these reports may have been based on fruiting material of *A. interior* of the northwestern Great Lakes region which had lost some of the pubescence on the ovary (as found to be the case for reports of *A. intermedia* from northwestern Ontario). The following key will readily separate flowering *A. intermedia* from related Canadian species.

Key to Canadian flowering *Amelanchier* with glabrous ovaries:

1a. Leaves glabrous and purple at flowering; petals 10-20 mm long; lowest pedicels 25-50 mm long ..... *A. laevis*

1b. Leaves tardily pubescent and green or purple-tinged at flowering; petals 3-15 mm long; lowest pedicels 8-35 mm long 2

2a. Petals 3-10 mm long; leaves round-tipped ..... *A. canadensis*

2b. Petals 9-15 mm long; leaves pointed at tip 3

3a. Leaves purple-tinged, more or less expanded and becoming glabrous beneath during flowering; shrubs ..... *A. intermedia*

3b. Leaves green, small and folded at flowering, pubescent beneath after flowering; trees ... *A. arborea*

McAlpine, Donald F., Rachel H. Maillet, Andrew J. Albert, Laura M. Crossman, Rebecca R. Smith, and André Martel. 2007. A freshwater hydrobiid, cf. the Squat Duskysnail, *Lyogyrus granum* (Mollusca), widespread in the Hampton Marsh, New Brunswick. Canadian Field-Naturalist 121(1): 92-94.

In Canada, the Squat Duskysnail, *Lyogyrus granum,* is an apparently rare freshwater hydrobiid. We document putative *L. granum* to be widespread throughout the Hampton Marsh, New Brunswick, with densities sometimes exceeding 150 snails/m^2 on substrates ranging from vegetated organic detritus over mud, to sparsely-vegetated cobble/sand lakeshore. That our identification of *L. granum* from Hampton Marsh remains tentative, in spite of large samples, emphasizes the need for detailed taxonomic study of any putative *L. granum* populations in Canada. Such study will be necessary before the true conservation status can be determined for this and any related taxa, as yet unrecognized in Canadian material.

Key Words: Squat Duskysnail, *Lyogyrus granum,* Hydrobiidae, conservation status, New Brunswick.

Of the two species of freshwater hydrobiid snails recorded in Maritime Canada (Clarke 1981), the Ordinary Spire Snail, *Amnicola limosa*, and the Squat Duskysnail, *Lyogyrus granum*, the latter is very poorly known. In part, this is due to difficulties in identification; Smith (1991) notes that in Massachusetts *L. granum* and *L. pupoidea* will rarely be confidently distinguished from each other and Jokinen (1992) has reported sexual dimorphism within the genus that is poorly understood.

In Canada, *L. granum* has been reported from only two locations in south-central New Brunswick (Jemseg and Baker Brook) and 11 sites in Nova Scotia (COSEWIC 2003*). COSEWIC (2003*) suggested that *L. granum* is rare in Canada and that the only known Canadian populations in New Brunswick and Nova Scotia should be considered nationally significant. Nonetheless, a paucity of information on this species has led to a designation of Data Deficient by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). Here we document a *L. granum*-like hydrobiid to be abundant and widespread in the Hampton Marsh, New Brunswick.

Considered one of the largest and most diverse freshwater marshes in the Saint John River floodplain, the 2000 hectare Hampton Marsh (45°33'N, 65°50'W) consists of a series of eutrophic oxbows, tributaries and backwaters of the Kennebecasis and Hammond Rivers. The marsh has repeatedly been identified as a site of ecological importance within the province (Stocek 1984*; Dionne et al. 1988; Austin-Smith 1994*) and is currently designated as a wetland of significance by the Wetlands and Coastal Habitat Program of the New Brunswick Department of Natural Resources and Energy. Although about 40% of the land adjacent to the marsh remains forested (Austin-Smith 1994*), shoreline development, sedimentation, eutrophication, and pesticide introduction from upstream agricultural areas are issues of concern. The marsh is located largely within the municipal boundaries of Hampton and Quispamsis, two of the fastest growing urban areas in New Brunswick, and the Local Service District of Nauwigewauk (Austin-Smith 1994*).

Putative *L. granum* were discovered in the Hampton Marsh during the course of ongoing mollusc surveys on the lower Saint John River and tributaries (Sabine et al. 2004; McAlpine et al. 2005). Data reported here were collected from 20 June to 22 August 2005 from 25 survey sites scattered across the marsh. Survey sites had been selected based on study of aerial photos, topographic and nautical maps, and field inspection, to represent a variety of habitat types (i.e., lakeshore, river channel, backwaters, oxbows) within the marsh complex. Molluscs were collected using a combination of techniques that included SCUBA, snorkeling, dip netting, and sieving bottom sediments; voucher material of all mollusc species reported here has been placed in the New Brunswick Museum mollusc collection. To provide abundance estimates for putative *L. granum* in contrasting habitats within the marsh, 15 0.25-m^2 random quadrats were also sampled in ~ 1 m of water in August at three of the sites. Only live snails were tabulated in quadrats following the complete removal, sieving, and hand-sorting of the top 5 cm of sediment along with all aquatic vegetation. Hampton Marsh specimens of *Lyogyrus* were identified largely on the basis of the structure of the verge in fresh material as described and illustrated in Smith (1991) and Jokinen (1992), but reference was also made to shell and opercular morphology as noted by these authors, and by Clarke (1981). As well, comparison was made with Atlantic Canadian material in the collection of the Canadian Museum of Nature. Although *L. pupoidea* has not been recorded in Canada, our extensive series of specimens agree with Smith (1991), in that intermediates and extremes showing external morpholog-

TABLE 1. Densities of putative *Lyogyrus granum* in contrasting habitats in the Hampton Marsh, New Brunswick.

GPS	Habitat	Mean ± sd(/m²)	Range (/m²)	Associated molluscs[1]

[1] Ai=*Anodonta implicata*, Al=*Amnicola limosa*, Cd=*Campeloma decisum*, Ec=*Elliptio complanata*, Fp=*Ferrissia parallela*, Gd=*Gyraulus deflectus*, Ha=*Helisoma anceps*, Pa=*Planorbella campanulata*, Lr=*Lampsilis radiata*, Pc=*Pyganodon cataracta*, Ph=*Physa heterostropha*, Ss=Sphaeriidae sp., Sc=*Stagnicola catascopium*, Se=*Stagnicola elodes*, Vs=*Valvata sincera*, Vt=*Valvata tricarinata*

ical features of *L. pupoidea* are present. COSEWIC (2003*) notes the possibility of *L. pupoidea*, as well as closely related *L. browni*, overlapping the Canadian range for *L. granum*. Clearly there is a need for detailed taxonomic study of any putative *L. granum* populations in Canada before the true distribution and conservation status of this and related species in the country can be determined.

Putative *L. granum* are widespread throughout the Hampton Marsh, although they were noticeably absent from sites in the river channel, where currents of 0.1-0.3 m/sec were recorded, and in the lowest portion of the marsh where there is periodic intrusion of brackish water. Discounting two sites where brackish water clearly intrudes on occasion, we recorded *L. granum* at 17 of the 22 survey sites remaining. The limited habitat data available for *Lyogyrus* indicates that this species is generally found on organic debris and vegetation in standing water (Clarke 1981; Smith 1987*; Jokinen 1983). Currents at sites where we recorded *Lyogyrus* did not exceed 0.1 m/sec. COSEWIC (2003*) reports *L. granum* densities of up to 400/m²; densities in the Hampton Marsh were lower but sometimes exceeded 150/m² (Table 1). We found the highest densities along an open, sparsely-vegetated cobble/sand lake shore on rocks and on the living shells of the unionids *Elliptio complanata*, *Anodonta implicata* and *Lampsilis radiata*. *Lyogyrus granum* was also abundant in clear water on submersed vegetation where *Ceratophyllum demersum* dominated (lakeshore vs clear water; Mann-Whitney $U = 15$, $P > 0.05$) but significantly less abundant in a murky vegetation-clogged backwater channel characterized by *Vallisneria americana* and *Potamogeton perfoliatus* than on the rocky lake shore (lake shore vs backwater; Mann-Whitney $U = 25$, $P < 0.05$) (Table 1). Both of the more heavily vegetated sites were characterized by deep bottom layers of organic detritus over mud.

COSEWIC (2003*) suggests that the few sites from which the species has been recorded in Canada indicate either that *L. granum* is a habitat specialist, that human impacts are reducing the availability of suitable habitat, that *L. granum* is a truly rare species, or some combination of these factors. That the rarity of this species may only be apparent, due to a lack of collecting, is not mentioned. Jokinen (1983, 1992) found this snail to be uncommon in Connecticut, and both Smith (1987*) and Jokinen (1992) found the species to be rare in Massachusetts and New York, respectively. While *L. granum* may indeed prove to be naturally rare, this species is small and easily overlooked and there have been few detailed surveys of the freshwater gastropods of Atlantic Canada. That *L. granum* has been recorded from 11 widely distributed sites across Nova Scotia also suggests that further field investigation may show this species, in association with related taxa as yet unrecognized in Canada, to be more prevalent in the region than current records indicate.

Acknowledgments

Financial support for this project was provided through grants to DFM from the Community-University Research Alliance program of the Social Sciences and Humanities Research Council of Canada, The Salamander Foundation, the New Brunswick Wildlife Trust Fund, and the Province of New Brunswick Summer Mentorship Program for Female Students. Laurie Mills and James Wilson of the Hampton Area Environmental Group assisted with field arrangements while Archie and Connie Downey were unfailingly gracious in providing access to the marsh through their property and providing use of a wharf and other amenities; Gart Bishop and Geoffry McBriarty assisted with the field sampling of molluscs.

Northern Range Extension of the Pygmy Shrew, *Sorex hoyi*, in the Yukon

THOMAS S. JUNG[1], TROY D. PRETZLAW[2], and DAVID W. NAGORSEN[3]

Jung, Thomas S., Troy D. Pretzlaw, and David W. Nagorsen. 2007. Northern range extension of the Pygmy Shrew, *Sorex hoyi*, in the Yukon. Canadian Field-Naturalist 121(1): 94-95.

A Pygmy Shrew, *Sorex hoyi*, was captured in a pitfall trap on the Blackstone River (65°04.6'N, 138°10.8'W) in central Yukon. This represents a northern range extension of about 110 km for *S. hoyi* in the Yukon.

Key Words: Distribution, Pygmy Shrew, *Sorex hoyi*, Yukon.

Shrews, *Sorex*, have been undersampled in northwestern North America because they are often not the focus of surveys (Jarrell 1986; Nagorsen 1996) and they are not readily captured in traps designed for small rodents (Nagorsen 1996). As such, our knowledge of the distributions of shrews in northwestern North America (i.e., Alaska, Yukon, northern British Columbia, western Northwest Territories) is limited. In recent years, however, directed surveys of shrews in this vast region have resulted in discovery of a new species, the Alaskan Tiny Shrew, *Sorex yukonicus* (Dokuchaev 1997), and range extensions for a number of species (e.g., American Water Shrew, *S. palustris*, Jarrell 1986; Cook et al. 1997; Tundra Shrew, *S. tundrensis*, Nagorsen and Jones 1981; Alaskan Tiny Shrew, *S. yukonicus*, and Pygmy Shrew, *S. hoyi*, Peirce and Peirce 2000). Nevertheless, much work is needed to better understand the distributions of shrews in northwestern North America. Herein, we describe a northern range extension for *S. hoyi* in the Yukon.

During an extensive survey of the small mammal fauna along the Dempster Highway in central Yukon, a Pygmy Shrew was captured on 12 July 2005, 2 km west of the Blackstone River (65°04.6'N, 138°10.8'W), 129 km northeast of Dawson City. The shrew was captured in an unbaited pitfall trap installed flush with the substrate. Pitfall traps have been found to be particularly effective for Pygmy Shrews (Prince 1941). No other shrews were captured at this site. The specimen was identified using dental characteristics and keys in Nagorsen (2002) and van Zyll de Jong (1983). The specimen (Field ID: DEMP-0015) is held by the Yukon Department of Environment, but will be deposited at the Museum of Southwestern Biology.

Our record represents a northern range extension of approximately 110 km for *S. hoyi* in the Yukon. Youngman (1975) mapped the hypothetical range as being as far north as the Old Crow Flats (approximately 68°N). Prior to our capture, however, the northernmost specimen records of *S. hoyi* in the Yukon were from 22 km east of Dawson City (Youngman 1975; van Zyll de Jong 1983) and the abandoned village of Fortymile (64°25'N, 140°32'W), 67 km northwest of Dawson City (B. G. Slough and T. S. Jung, unpublished data).

This Yukon range extension of *S. hoyi* is not surprising as there are more than 125 specimens held at the University of Alaska Museum of the North that were collected north of 65°N in Alaska, with the most northerly taken near the Dalton Highway at the Dietrich River (67°37'N, 149°46.8'W; UAM 23050). In

addition, van Zyll de Jong (1983) reported specimens from Chick Lake and Fort Franklin, two locations north of 65°N in the Northwest Territories. It is likely that *S. hoyi* ranges further north in the Yukon; this is a species of the boreal forest and it likely extends north to the treeline. Further observations are needed to document the range of *S. hoyi* and other soricids in the Yukon and elsewhere in northwestern North America (Cook et al. 1997).

Acknowledgments

We thank Kevin Lake, Elise Bolduc, Kyle Russell, Kieran O'Donovan, Shannon Barker, Lea Randall, Brian Bell, Sara Nielsen, Michael Smith, Becky Cadsand and Matthias Clyde for able assistance in the field or lab. Funding for this work was provided by McGill University, the Yukon Department of Environment, and NatureServe Yukon. We thank Murray Humphries, Julie Frisch and Gordon McRae for logistical support while on the Dempster Highway.

A Tribute to Neal Philip Perry Simon 1973-2006

Tony E. Chubbs[1] and Frank R. Phillips[2]

[1]Department of National Defence, 5 Wing Goose Bay, Box 7002, Station A, Happy Valley-Goose Bay, Newfoundland and Labrador A0P 1S0 Canada; e-mail: techubbs@cablelab.net

Chubbs, Tony E., and Frank R. Phillips. 2006. A tribute to Neal Philip Perry Simon, 1973-2006. Canadian Field-Naturalist 121(1): 96–99.

Neal Philip Perry Simon, our friend, hunting companion, and colleague, was born in Labrador City, Newfoundland and Labrador, on Sunday 30 December 1973, to Dave and Doreen Simon. He passed away suddenly and unexpectedly in a tragic accident on 23 September 2006, at the age of 32 near Happy Valley – Goose Bay where he resided since 1988. His parents, Dave and Doreen Simon, sister Nicole and fiancée, Leanne Elson, survive him. Neal had a mutual adoration for his grandparents, Carrie and Gordon Templeman, who will miss him dearly.

Neal's early education was in Catholic schools: Notre Dame Academy (primary and elementary) and Labrador City Collegiate (high school) both of which were in Labrador City and have since closed. Neal, along with his grade school pal Colin Carroll, developed a keen interest in biology at an early age, trying his hand at taxidermy in grade seven. Francis Schwab, Neal's first year university professor, was instrumental in introducing him to scientific research, especially the effects of post-fire succession on songbird abundance. His post-secondary education began at Memorial University of Newfoundland in St. John's, Newfoundland and Labrador, where in 1995 he obtained a B.Sc.(Hons) with a major in ecology and evolution and a minor in statistics. It was there, under the instruction of Eric Baggs and the late Dr. Gary Cowen, he was instilled with an appreciation of the importance of small mammals in understanding forest structure dynamics.

In 1996, Neal began his Master of Science in Forestry at the University of New Brunswick under the supervision of Dr. A. W. Diamond. As part of the Atlantic Cooperative Wildlife Ecology Research Network (ACWERN), Neal regularly contributed presentations at the annual workshop from 1998 to 2003. In 2000, Neal continued under the supervision of Dr. Diamond to pursue his Ph.D. on the effects of site productivity and heterogeneity on bird habitat quality and species richness. His research ranged from modelling species distributions to studying the effects of landscape features on habitat use by passerines, with a focus on their demography. Much of Neal's work had an overlying conservation theme linked quite strongly to ecological theory. Neal completed his Ph.D. in 2005 and was about to embark on his post-doctoral research in the spring of 2007.

Neal taught in various capacities at Memorial University of Newfoundland, the University of New Brunswick and St. Mary's University. From 1996 to 1998, Neal worked as a contract biologist for the College of the North Atlantic in Labrador City and Happy Valley – Goose Bay where he also offered his services as a university tutor in various disciplines, including chemistry and biology. Neal was always there to help out whenever or wherever he could and would always without hesitation say "Yes, just provide me the materials." Students found him friendly and informative and they usually had few problems grasping concepts from him. He will be remembered for his willingness to help, his ability to teach a difficult content area and his friendly personality.

From November 1998, Neal was employed by the Provincial Government of Newfoundland and Labrador, Department of Natural Resources, occupying the position of Regional Ecologist for the Labrador Region. Neal's work concentrated on experimental design, data collection, and analysis of research projects relating to forest management plans in Labrador. Neal's research interests included effects of forest management and changing forest structures and specifically how these changes may affect the spatial and temporal distribution of threatened Woodland Caribou (*Rangifer tarandus caribou*) in central Labrador. Neal's most recent interests involved sustainable forest management in collaboration with the Government of Newfoundland and Labrador, Department of Natural Resources, and the Université du Québec à Montréal. Neal was about to embark on his post-doctorate research using innovative simulation models to ensure the sustainable management of Labrador's forests while his fiancée and co-worker Leanne would be completing her Master of Science in a supporting area of research. Neal was one of those rare ecologists who not only recognize the power of quantitative methods, but also actually understand how to appropriately apply these methods. Having just barely embarked upon his research career, Neal, as attested by his already growing list of publications, was destined for greatness in the world of research and statistics.

Since the summer of 2000, Neal had been an active participant in the North American Breeding Bird Survey (BBS) program and ran the Newfoundland and

FIGURE 1. Neal P. P. Simon holding his first seal darted off Mulligan Point, 2 May 2003. (Photo courtesy Sarah Townley).

Labrador, Happy Valley – Goose Bay survey route for Environment Canada. Neal was also a committed participant in the Christmas Bird Count (CBC).

Neal was a dedicated member of both the local Squash League and Goose Bay Judo Club. He exemplified the philosophy of Judo in all aspects of his life, striving to maximize his physical, intellectual and personal character by doing his best; and being his best, Neal truly reflected this teaching through his physical strength and fitness, his academic accomplishments and desire to learn. As a competitor, Neal was intense and spirited while always maintaining his youthful grin and sense of humour. Neal's enthusiasm for research in ecology and his jubilant attitude radiated from him, rapidly instilling in his colleagues a source of continual positive motivation. With an acute and intense sense of humour, Neal added a unique and welcome aspect to his interaction with both friends and fellow researchers. As an editor and reviewer of prospective manuscripts, his dedication and support were immeasurable and will be greatly missed.

In 1999, Neal was an original member of the Labrador Wolverine Working Group, and became one of the founding members of the Labrador Woodland Caribou Recovery Team in 2001. Neal was a member of The Society for Conservation Biology, the Wildlife Society, the Atlantic Region of the Canadian Climate Impacts and Adaptation Research Network, the Atlantic Society of Fish and Wildlife Biologists, Atlantic Co-operative Wildlife Ecology Research Network

(ACWERN), Newfoundland and Labrador Biodiversity working group, Forest Management Planning Team Member for Labrador Districts 19, 20, 21 and 22 and a member of the Institute for Environmental Monitoring and Research – Osprey Technical Committee. Neal was about to join the Groupe de recherche en écologie forestière interuniversitaire at l'Université du Québec à Montréal to complete his post-doctoral research developing habitat and timber harvesting-conservation trade-off models for Woodland Caribou.

Neal's interests were varied and included, but were not limited to, modelling species movements, predicting species distributions and understanding the effects of forest management on species occurrence and demography. He spent most summers in Labrador, along with his students and co-workers; in the field conducting songbird point count samples and vegetation plot counts.

We came to know Neal and build a strong friendship when he moved to Happy Valley – Goose Bay in 1998 and shortly thereafer began work as the Ecosystem Ecologist for Labrador. Neal was friendly, energetic and an avid waterfowl and big game hunter. We anxiously awaited mid spring each year when we would travel by snowmobile over the bay ice to Portage Island, Mulligan Point. Here we would participate in the eons old traditional Inuit hunting practice of waiting patiently at breathing holes for Ringed Seals (*Pusa hispida*). Evenings would be filled with laughter as we swapped humorous exaggerated stories of past good times. Such wonderful times were set against the backdrop of a blazing driftwood fire and the assurance of deep slumber later in our traditional Labrador canvas tents heated with the warmth of woodstoves. Neal often swapped related stories of how he had enjoyed the outdoors with his best hunting buddy, his father Dave, in Western Labrador. It was more important to Neal to enjoy the outdoors than to be successful on a hunt, though more often than not he was. As he so often mentioned to his hunting partner Colin Carroll, "If we don't get anything today, it doesn't matter. Just being here doing this is making my day."

His friends will best remember Neal as a shining, though comedic intellectual, with a love of life and a passion for the outdoors. Through discussions with some of Neal's colleagues and friends in the preparation of this tribute, we have found that Neal existed in several parallel universes, having the same mannerisms, characteristics and sharp wit despite the varied personalities and context of his friends. He will be remembered for his comic additions to his work and conversation slipping easily between extreme seriousness and laughter.

Acknowledgments

We thank Neal's parents (Dave and Doreen), his sister Nicole, fiancée Leanne, and others for personal information. Colin Carroll, Neal's schoolmate and colleague provided information on Neal's early schooling in Labrador City. We thank Tony Diamond for providing a compilation of Neal's academic achievements. Matt Betts and Joe Nocera provided insight on Neal's life that could only be shared between close colleagues and best friends. Bob Simms shared personal interactions with Neal through their judo club and Bernice Tracy provided details of Neal's association with the College of the North Atlantic. Finally, we would like to thank all of Neal's friends, family, colleagues and acquaintances that contributed to the Neal Simon Memorial Trust to fund an academic scholarship in Neal's honour and memory. Neal appreciated the outdoors and enjoyed hunting and fishing and spending time in the Labrador wilds with Leanne and his dog, Boss. He will be greatly missed by his family, his many friends and his academic colleagues.

Book Reviews

ZOOLOGY

Amphibians and Reptiles of British Columbia

By Brent M. Matsuda, David M. Green, and Patrick T. Gregory. 2006. Handbook, Royal British Columbia Museum, Victoria, British Columbia. 266 pages. $17.33.

The British Columbia Provincial Museum (now the Royal British Columbia Museum) was second only to the Royal Ontario Museum to issue guidebooks to their provincial amphibian and reptile faunas for the public (by E. B. S. Logier in 1937 and 1939 for Ontario, and Clifford Carl in 1943 and 1944 for British Columbia). The Carl guides (Handbooks 2 and 3) subsequently went through reprintings with some revisionary material added in 1951 and 1968. In 1984 completely rewritten guides were published on reptiles (Handbook 44 by Gregory) and amphibians (Handbook 45 by Green), both coauthored with R. Wayne Campbell.

Now a new handbook (unnumbered) is a combined revised and partially rewritten text from the earlier Green and Gregory texts with updated distribution maps and the addition of a new coauthor. The previous authors are long-established, still active research herpetologists with extensive publications, Green primarily on frogs (in the broad sense including, as well as typical "frogs", toads, treefrogs, spadefoots, tailed frogs) and Gregory primarily on snakes but also including lizards, turtles and some amphibians. Dr. Gregory has spent his entire post-graduate career at the University of Victoria; Dr. Green was born British Columbian but his post-graduate career has been at the Redpath Museum at McGill in Quebec. Both have extensive field experience in British Columbia. The new addition, Matsuda, is characterised in the tongue-in-cheek authors' profiles (page 258) as an "overachieving ectotherm" (although this is surely not a unique characterization within this triumvirate) with a UBC M.Sc. who is now settled in British Columbia as an environmental consultant.

This handbook, like its predecessors, follows a standard guide layout. Preface, introduction (covering a wide range of aspects of amphibians and reptiles in general), checklist and conservation status, individual species accounts (for 39 species of which 4 are definitely and 2 possibly introduced) and a further section which includes additional introduced species which apparently have not persisted or whose occurrence is only speculative, an appendix which gives contact information for regional authorities, glossary of terms, bibliography (divided into additional reading and references), acknowledgements (about authors with illustrator credits) and an index. The black-and-white text drawings are mostly repeats from the earlier guides except for newly included wall lizard and all of the amphibians. A few of the latter are superior to those of the earlier amphibian guide but many are not. The new salamander drawings are particularly disappointing with the number of costal grooves shown rarely agreeing with the counts given in the text. However, all are sufficient for identification. New are 60 small colour photographs inserted between pages 186 and 187.

Additions since the last guide new to British Columbia and Canada are the secretive salamander *Plethodon idahoensis* and the introduced European wall lizard *Podacris muralis*. Also new is the conclusion from molecular evidence by T. R. Jackson in 1998 that the *Aneides* salamander on Vancouver Island is an import with bark from California, *A. vagrans*, and not the geographically closer *A. ferreus* to which it had long been assigned. Other nomenclature updates from recent revisionary studies are *Dicamptodon tenebrosus, Ascaphus montanus, Spea intermontanus, Actinemys marmorata, Pseudacris maculata, Rana luteiventris, Pituophis catenifer,* and *Crotalus oreganus*. One accepted elsewhere that was not made is *Pseudacris* for *Hyla regilla,* and the more controversial generic changes *Lithobates* for *Rana sylvatica* and *Rana pipiens* (but not for *R. aurora, R. pretiosa,* and *R. luteiventris*) and *Anaxyrus* for *Bufo boreas*, even though one of the authors (David Green) is a coauthor on the paper detailing the latter changes (American Museum of Natural History Bulletin 297).

Many incidental facts liven the text (such as the observation that frogs always close their eyes when they leap (page 14)), that frogs can "hear" ground-borne vibrations by transmissions through their front legs (pages 21-22) and that females of many turtles species can store sperm from a single male for up to four years (page 32).

The marine *Cadborosaurus* and the Okanagan Lake "Ogopogo" are only mentioned under folklore (page 49) with the (arguable by some) statement "Sporadic sightings of these beasts continue, but evidence of their existence is lacking."

Few slips were missed in proofing such as the failure to italicise *Hyla versicolor* and *H. chrysoscelis* on page 29, and the only British Columbia specimens of the horned lizard *Phrynosoma* given as "two near Osoyos in 1898" on page 182 but as "two records from Osoyos area in 1910" on the facing page 183 (the first is correct).

This guide brings British Columbia herpetology effectively into the 21st century as to be expected from the distinguished authors. It is a must for any west coast naturalist's bookshelf and/or field jacket with an outsized pocket.

Blue Grouse: Their Biology and Natural History

By Fred C. Zwickel, and James F. Bendell. 2004. National Research Council of Canada, Ottawa, Ontario. 284 pages. $69.95 Paper.

This monograph is the culmination of two lifetimes devoted to studying Blue Grouse population biology and behaviour, both in the field and in aviaries, predominantly in coastal British Columbia. One of the advantages of a lengthy monograph is that the authors were able to synthesize much unpublished data and "gray" literature in addition to published references, making it the most comprehensive reference on this species group that is currently available. As such, it is not a book for the general reader of natural history (the colour and black-and-white photographs scattered throughout are quite small), but a scientific reference full of tables and graphs and lots of detail (there are 12 pages each of references and results of statistical tests).

Unfortunately, only two years after Zwickel and Bendell's monograph was published, the American Ornithologists' Union (Banks et al. 2006) re-split Blue Grouse into two taxa, *Dendragapus obscurus* in the Pacific Coast Range and the Sierra Nevada, and *D. fuliginosus* in the Rocky Mountains. These two taxa had originally been considered two species (Brooks 1929), but were conspecific for most of the 20th century. The re-split resulted from the recent DNA-based work of Barrowclough et al. (2004), who also found that the New Mexico populations of Dusky Grouse were perplexingly different, but not enough to consider them separate species. Populations in the northern parts of the range (i.e., north of the Chilcotin in central B.C., through to Alaska) were not included in the Barrowclough et al. study, but the separation into coastal and inland species is assumed to hold true. Unfortunately, the AOU split makes the monograph more difficult to use, but in their favour, Zwickel and Bendell use the scientific names, often with full trinomial reference to the eight accepted races at the time of publication, throughout, as well as referring to "coastal" and "interior" subspecies analogous to the new split. I recommend that the serious reader really study the chapter on taxonomy and distribution with Barrowclough's paper (available on the internet) in hand.

As a serious naturalist, I found the chapters on historical review, physical environment, integument (plumage especially), behaviour, habitat use and movement, population parameters, predators and disease the most interesting. The seven chapters on form and function – integument, morphology, reproduction, growth and development, food and nutrition, energetics and genetics – will be of interest mostly to serious students of Blue Grouse.

Although Zwickel and Bendell refer to studies from other parts of Blue Grouse range, they admit that the strong focus on the coastal species (*D. fuliginosus*) is unfortunate because there are a number of characteristics, such as vocalizations, that are clearly different between the two species. The authors hint at a future publication that will explore the population ecology of Blue Grouse, and it is to be hoped that they are able to overcome this geographical disparity.

Birds of Peru

By Thomas S. Schulenberg, Douglas F. Stotz, Daniel F. Lane, John P. O'Neill, and Theodore A. Parker III. 2007 Princeton University Press. 656 pages. U.S. $49.50 Cloth.

In 2001 I was delighted to find *Birds of Peru*, by J. Clements and N. Shany. It was a good modern field guide and proved its worth in Peru. However, there were a few times when I needed to borrow a more comprehensive text to be certain of my identification. Now we have a new guide by Schulenberg et al. and the obvious question is whether it is an improvement.

The first difference is that the new guide has range maps. This means I do not have to struggle with phrases such as "on the east bank of the Rio Utacamba at the south end of Cordillera de Colon." [Marvelous Spatuletail] Now I can look at the map and have an immediate understanding. The range maps are conveniently set

next to the text in what is normally the margin, making great use of space. This alone is a great improvement.

Peru has about 1800 species or one fifth of the world's birds. Most sources cite this vague number. The few that are more precise give numbers that vary by up to 100 species. It is not surprising that a state of flux exists in such a vast and complex area. This book covers 1792 species which is probably as good as you do under such fluctuating circumstances. Trying to reconcile the list of species covered by both books or given in other sources is very difficult. It is a bit like trying to compile a list of "honest" politicians. The new book drops some questionable records like Plumbeous Ibis [one old, suspect, badly labeled specimen] but adds Bogota Rail [based on a current valid sighting.] Some birds are treated by Shulenburg as sub-species; Andean Ibis is listed as a sub-species of Black-faced Ibis whereas other sources give it full species status. There are complications due to name changes. For example, there are four toucans listed in both books. However, the names do not correlate well. This includes the scientific binomials, normally a very stable source of information. The old book has Toco Toucan *Ramphastos toco*, Black-mandibled Toucan *Ramphastos ambigus* Yellow-ridged Toucan *Ramphastos culminates*, and Cuvier's Toucan *Ramphastos cuvieri.* The new book has Toco Toucan *Ramphastos toco*, Black-mandibled Toucan *Ramphastos ambigus* plus White-throated Toucan *Ramphastos tucanus*, and Channel-billed Toucan *Ramphastos vitellinus*. The last two are new names for Cuvier's and Yellow-ridged Toucans. [Speciation in the whole toucan complex is confused.] I also noted that Andean Flamingo and James's [Puna] Flamingo have been updated to *Phoenicoparrus andinus* and *Phoenicoparrus jamesi,* respectively, but the Guanay and Red-legged Cormorants have not been changed to *Leucocarbo bougainvillii* and *Leucocarbo gaimardi*. So those with a penchant for lists may need to do some research. That being said, this book is more than adequate as a field guide for the resident and visiting birder alike.

The color plates are opposite the descriptions and distribution maps. There are 13 illustrators, so there is some difference in style. The most disparate are Laurence McQueen and John O'Neill. O'Neill's work has the precise, almost photographic rendering we see in most modern field guides. McQueen's paintings are more flowing and look like paintings. My junior school art teacher would have said they were more "painterly." Daniel Lane's work is somewhat in between these two styles. Which style you like is a matter of taste. I have looked at many of the illustrations for accuracy and can find no problems. In fact, I particularly like the toucanets by O'Neill and the jaegers by McQueen. There are 4000 color illustrations at about six to a plate, meaning the illustrations are quite large [again the publisher has used the margins].

In addition to the species accounts there are well-written sections on Habitats, Molts-and-Plumages, and Conservation. In particular the terminology used for habitat in the species accounts is clearly documented. The text in the species accounts covers the key identification features, status, distribution, and song.

This book will please birders and biologists living in or visiting Peru. It is also useful beyond the borders of Peru into adjacent areas of South America. It is a little on the heavy side for dragging through a hot jungle, but what else can you expect with such an enormous bird list.

ROY JOHN

2193 Emard Crescent, Ottawa, Ontario K1J 6K5 Canada

The Freshwater Fishes of British Columbia

By J. D. McPhail, illustrated by D. L. McPhail, foreword by Joseph S. Nelson. 2007. University of Alberta Press, Edmonton. lxxiv + 620 pages. $90.00.

This book is the latest treatment covering the freshwater fishes of British Columbia. Earlier books appeared in 1948 (132 pages) and 1967 (192 pages). They were published by the British Columbia Provincial Museum (now Royal British Columbia Museum) while the latest book is published, strangely, in Alberta. The present volume is 694 pages long with a larger format and is indicative of both the growth in knowledge and the need for a comprehensive work on this provincial fauna.

The book is composed of introductory sections covering purpose, use of keys, names of fishes, layout of the book, origins of the fauna, present distributions, and conservation. The sections on glacial events and current distributions are a very useful synthesis as is the discussion on what a species is and why the various forms of sticklebacks and others have not been named taxonomically.

The bulk of the text is the descriptions of species. Family accounts give general information on the included species and the identification keys are found there. The species accounts are preceded by a pictorial key to families that works for the more distinctive body shapes but would have benefited from some annotations for those fish that are more similar in shape to enable the naïve reader to correctly identify the family. It is always a debate as to whether keys should be with the family or should form a separate section. The former works when reading through the book but the latter is much easier for the actual identification process in a laboratory or the field. The keys are well illustrated al-

though both illustrations and text are too small. Particularly useful are keys to fry, parr, and adult salmons and trouts as these life history stages differ in appearance.

Each species account has a scientific name (but no date with the author), English common name, a black-and-white illustration, sections on distinguishing features, taxonomy, sexual dimorphism, hybridization, distribution with a spot map, life history, reproduction, age, growth and maturity, food habits, habitat and conservation comments.

A total of 81 species are covered, including 10 exotics. The main families of the 17 known from British Columbia are salmons, trouts and whitefishes with 23 species, minnows (20), and sculpins (8). Minor errors are inevitable in any work; e.g., Lindsey is misspelled in the dedication, Qadri as Quadri in the References, but some can be confusing; e.g., on page 498 *Pomoxis nigromaculatus* is said to have 5 anal spines in the sunfish identification key but most fish have 6-7 spines; the stickleback key separates two species by non-overlapping dorsal fin spine counts (which do, however, overlap occasionally) where in one species (*Pungitius*) the spines are staggered left to right, an easily seen and unique character (mentioned in Distinguishing Characters).

The book ends with an extensive Bibliography, an Appendix I (a checklist of the fishes, with no other appendices), a Glossary and an index to scientific and common names. The Glossary explains a variety of terms, even that the plural of dentary is dentaries which is fairly standard English, but gives axillae without explaining it is the plural of axilla (a knowledge of Latin is ever more dead). One obscure word is snye, defined as a dead-end side channel. This is listed in dictionaries as an Ontario word and can also mean a channel joining two rivers.

Cost is increasingly a factor in production of books and this may explain the absence of any colour plates. In my mind this argues for including a CD/DVD with the book to carry photographs of habitats and coloured depictions of fishes. The text can also be put on the disk, making the book searchable. I still prefer a book in the hand to a computer screen but suspect this does not apply to a younger generation. Even the CD in a pocket at the back of the book is a transitional stage and "books" should now appear on the internet, thereby saving trees, allowing a plethora of colour plates and other illustrations, enabling the author to receive and incorporate feedback and new data, and facilitating correction of errors of fact and of omission. A "book" on a website can be built up incrementally although some will inevitably fail to reach a completed form. Each stage allows for criticism and correction, from the initial checklist of species, the identification keys, distribution maps (allowing zoom-in for finer details than part of a book page allows), and finally text descriptions.

For those worried about vanishing websites, EM pulses and cyber trashing, a printout of say 20 copies of the digital "book" can be deposited in various libraries. This trend can be seen in some scientific works such as the "Annotated Checklists of Fishes" produced by the California Academy of Sciences which are on-line at that institution but have copies deposited in a minimum of six natural history institutions worldwide, admittedly as CDs.

This is the definitive book on this fish fauna and an essential tome for any student of the aquatic environment in British Columbia. Future versions will require multiple authors to match and improve on the experience and knowledge exhibited here by Don McPhail.

BRIAN W. COAD

Canadian Museum of Nature, P.O. Box 3443, Station D, Ottawa, Ontario K1P 6P4 Canada

Owls of the World

By J. Duncan. 2003. Key Porter Books, Toronto, Ontario. 319 pages. Hardcover, $60.

This beautiful book actually fulfills the two roles that many natural history books aspire to but usually fall short of … being both a detailed scientific reference and easy to read. The first two-thirds of the book cover the biology and life history of owls, stories by people who have uncovered these amazing details and the methods they used, the substantial role that owls have in mythology around the world, and threats to their survival (but also the passion and hope that people hold out for owls). The U.S. edition, published by Firefly Books, carries the apt subtitle "their lives, behaviour and survival".

The last third of the book is a detailed look at 205 species of owls: physical description, habitat, natural history, general distribution and their global conservation status. Even a quick look highlights how difficult it is to study some of these species, as many do not have photographs.

Duncan brings not only his own wealth of knowledge and field experience (particularly with Great Gray Owls) to this task, but also those of a "whoo's whoo" in the world of owls, such as Robert W. Nero, Irina Menyushina, C. Stuart Houston, and Aki Higuchi. Duncan's use of anecdotes helps to de-mystify science and raises the readability level, such as when he relates being dared to taste a freshly regurgitated owl pellet in front of a crowd. He said it tasted "sweet," but his incredulous darer (R. W. Nero) bit into it and quickly spat it out, declaring that it tasted "bitter." They were both right … the pellet is coated with a pH-neutral film of mucous that protects the owl's throat and mouth from the low-pH acid-soaked mass of fur and bones, which Nero had bitten into!

As with many species, owl populations are often in trouble around the world for the usual reasons: habitat destruction, direct (vehicles, shooting, trapping) and indirect (hitting barbed wire fences) mortality, and invasive alien species such as West Nile virus. But Duncan argues that an awareness and understanding of how people have perceived owls in the past may help support efforts to conserve them today.

The one small section of the book that many people will struggle to read describes the DNA sequencing and classification of owls. It would have been more understandable if Duncan had linked this highly technical description, especially the Maximum Likelihood Tree showing owl relationships, to some of the species accounts, where it is obvious from a glance at range maps for many of the Scops Owls in the Malaysian archipelago that these species probably had a common ancestor, and allopatric speciation occurred due to island isolation.

The photos in this book are luscious, with rich colour. Today, I randomly opened it and there was a full-page picture of Verraux's Eagle Owl – the best photo that I've seen of this owl that adequately shows its pinkish-purple eyelids. I recall driving along a sandy track in Chobe National Park in Botswana when one of my companions excitedly sputtered "purple eyelids, purple eyelids," as she pointed at the bird that had caught our attention in the guidebook!

Excuse me while I read up on the Tucuman Pygmy Owl before heading off to Argentina ....

Ecology, Conservation, and Status of Reptiles in Canada

Edited by C. N. L. Seburn, and C. A. Bishop. 2007. Herpetological Conservation volume 2. Society for the Study of Amphibians and Reptiles, Salt Lake City, USA. x + 246 pages. illus., hardbound. Available from the Publications secretary of SSAR, ssar@herplit.com/U.S. $40 plus shipping.

This book is an edited compilation of peer-reviewed contributions on several aspects of conservation and more specifically, on the ecology of the reptiles that occur in Canada. It contains chapters by many (figurative) heavyweights of Canadian herpetology, who bring combined centuries of experience to the project. The book is a very good application of accumulated biological knowledge to the question of conservation. It is also a good example of how a professional community can collaborate in a common cause.

It begins with a short introduction, then a historical review of work done on reptiles in Canada. Next are four chapters summarizing the life history of lizards, snakes, freshwater turtles, and marine turtles. Contributions on the applications of genetics to conservation, health and disease in reptile populations, and traffic mortality follow. The future of Canadian reptiles and a strategy for conservation are discussed. The book ends with an illustrated checklist of species, with the official conservation status of each. There is also a comprehensive summary of literature, both historic and recent, with few omissions.

The book succeeds in its aim of providing a summary of the biology and conservation status of Canadian reptiles. The chapters are of a consistently high calibre – a testimony to the knowledge of the authors and the thoroughness of the editors. The book is useful on more than one level – as a summary of reptile ecology in Canada and as a conservation guide; the extensive literature is also a valuable resource.

Several themes are common to the contributions. Reptiles living in Canada face two problems – the climate and humans. Because climate affects life history, reptiles are concentrated in southern Canada, where it's warmer. Unfortunately for the reptiles, humans are concentrated in the same areas. Human activities that result in habitat modification are usually in direct conflict with the best interests of reptiles.

The book makes the point that although the Canadian climate may not be ideal for reptiles, they have adapted to life here. A reader soon realizes that many, if not all, declines in reptile numbers are due to human action. For example, road mortality is a common theme in several chapters. Human alterations to the landscape can have direct effects such as habitat destruction, and also secondary effects such as increases in reptile predators like cats and raccoons. Several authors make the point that declines in reptile, especially turtle, populations can occur slowly, drawing little public attention.

Although I was familiar with much of the information presented, there were some surprises, one being the high number of marine turtles off the Atlantic and Pacific coasts. This is but one example of how much is still not known about our reptile fauna.

Quibbles are few and minor. Colour variations and aberrant scutellation in turtles should not be included among diseases and parasites; the authors themselves admit that these "..are not detrimental..." (page 149).

What is the prognosis for reptile conservation? Although knowledge of the need for conservation is high among the public, and although the number of conservation programs is high, the future still looks bleak, because of the juxtaposition of human and reptile populations. The point is made repeatedly that while atlases and monitoring programs are good, they are ultimately ineffective without concrete action; "...ecological knowledge alone will not save species when the real problems facing them are social and political." (page 47).

ROSS D. MACCULLOCH

Rodent Societies: An Ecological & Evolutionary Perspective

Edited by J. O. Wolff and P. W. Sherman. 2007. The University of Chicago Press, Chicago, 610 pages. U.S. $49. Paper, $125 Cloth.

This opus on rodent behaviour brings together 61 researchers in a single edited volume. There are 42 chapters grouped into various topics including systematics, sexual behaviour, life histories, behavioural development, social behaviour, antipredator behaviour, comparative socioecology, conservation and disease. The main objectives are to present the latest research on the behaviour of rodents and to place it in the context of ecology and evolution. The resultant compilation of papers is firmly based on comparative biology, which goes beyond merely describing phenomena and explains it in terms of the larger ecosystem and within a phylogenetic framework. There is an emphasis on hypothesis testing and explicit experimentation that results in robust and scientifically-sound studies. This approach fostered by the editors gives more than just summaries of particular topics but highlights the ongoing nature of our understanding of behaviour in not only rodents but also as related to other organisms.

At over 2200 species, Rodentia is the most speciose order of mammals and accounts for approximately 40% of the diversity. In terms of breadth of coverage, almost half of the chapters summarize behavioural data across all major lineages of rodents or within a higher-level classification. In addition, many different groups or species of rodents are directly studied as case examples in this compendium, with taxa examined ranging from squirrels to beavers to rats to capybara.

After an introductory chapter on rodents as model systems, the evolutionary background is set with a paper discussing phylogenetics and biogeography. This is followed by several chapters on sexual behaviour dealing with mating and reproductive strategies. Life histories of rodents are covered by topics on dimorphism, sex ratios, stress, dispersal and philopatry, gene dynamics, and self-regulation. There is discussion of behavioural development such as neural regulation, ontogeny, learning, and kin recognition. Social behaviour is examined with papers on parental care, ecology of sociality, scent marking, non-parental infanticide, monogamy, and pacifism. There is a small section with three chapters on antipredator behaviour including alarm communication. Comparative socioecology has several papers on social organization and structure of a number of different species or higher-level groups. The book ends with a section on conservation and disease followed by a chapter summarizing conclusions and future directions on the research of rodent behaviour.

One weakness in an otherwise comprehensive anthology was the lack of molecular study on the genetic basis for much of the evolution of behaviour. In particular, DNA sequence data nowadays seems to be churning out by the genome. Was this an editorial oversight, or is there just nobody looking into this field of research for rodents? If so, this highlights an area that needs attention, especially since there are several candidate model-system species in rodents to choose from. Likewise, I found it odd that only four of the chapters have figures of phylogenies, considering that an evolutionary perspective is supposed to be one of the major underlying themes of the volume. Perhaps this is an indication that there is still an obvious gap that requires bridging between micro- and macroevolution.

Another observation is that over 80% of the authors are based at institutions in the Americas. Has this biased the presentation of the state of knowledge of rodent behaviour? A more subjective criticism is the combined literature cited section for the whole book. For edited volumes, I prefer references listed separately at the end of each chapter, especially when topics are as varied as this monograph. However, there are some advantages such as the elimination of repeated citations for general publications on rodents and a single compiled source useful for searching purposes. Nonetheless, these minor detractions by no means diminish from the scientific merits of the book.

This book is definitely aimed at the specialist researching the behaviour of rodents, but will also be of interest to biologists working on other organisms and studying similar social systems. At over 600 pages, the price is reasonable for purchase by a university library, or would be a valuable addition to any ecologist's bookshelf because it is packed with the latest information on ethology.

Seashells: Jewels from the Ocean

By Budd Titlow. 2007. Voyageur Press, 729 Prospect Avenue, P.O. Box 1, Osceola, Wisconsin 54020. 112 pages. US $20. Cloth.

Sea shells have fascinated people since the dawn of time. Intrinsically beautiful, they have inspired artists and architects, been used to fashion tools, and have even served as money. They are also the prize of collectors the world over. All of these themes feature in Budd Titlow's handsome book *Seashells: Jewels from the Ocean*.

This relatively slender volume, copiously illustrated with photographs by the author or from stock footage, provides a good introduction to the world of mollusks and the shells which adorn so many of them. Successive chapters deal with the physiology of mollusks, their classification, their habitats, their cultural and econom-

ic importance to humans, and the threats that mollusks face. The latter include marine and land-based sources of pollution and over-exploitation of commercially valuable species.

There is also a primer on shell collecting, and also short notes on good collecting sites in North America. At its heart, this is a book aimed at shell collectors, be they casual beachcombers or fanatical conchologists. The former will learn much, the latter will no doubt admire the stunning photographs. There is a distinct American bias, both in the selection of photographs and in the shell collecting sites profiled; indeed at times the book reads as an ode to Sanibel Island, Florida, the Mecca of American shell collectors.

The book oscillates between straightforward explanations in layman's terms of the science underpinning malacology, and a rather folksy, and at times highly personal, appreciation of the cultural aspects of sea shells and shelling. While occasionally rather affected, on the whole it is highly readable. Many of the photographs selected sacrifice ecological verisimilitude for art; for example, there are several very beautiful assemblages that would be highly improbable in nature. And, belaying the book's American bias, it would be a fortunate day indeed where one found a Spider Conch (from the tropical Indo-Pacific) on a North American beach. For a field naturalist, the book is faintly disappointing in that it tends not to identify in specific terms most of the shells portrayed. Shelling, unlike birding, is one pastime where getting a grip on the Latin terminology and the taxonomy is essential; for this the reader would be well advised to turn to any one of the several excellent works cited in the short but useful reference section. By the same token, a few sketches illustrating such things as mollusk morphology would have been helpful.

There are a few errors in the text; for example the swans that winter at Chesapeake Bay are Tundra Swan, not Trumpeter Swan, but these errors do not detract from the overall value of the book. One somewhat disappointing aspect of the book, and one in counterpoint to the otherwise conservationist approach, is a section dealing with the collection of live specimens. While pale in comparison to other threats, collectors can pose a considerable threat to vulnerable species and it would have been preferable if the author had concentrated the reader's attention on the collection of non-living material. That said, the author does emphasize the need to respect local regulations. In conclusion, this book is not a scientific reference; however, it does provide a useful primer for anyone keen to explore the world of shelling, and a handsome addition to any collection of "coffee table" books.

Turtles: An Extraordinary Natural History 245 Million Years in the Making

By Carl J. Franklin. 2007. Voyageur Press, 729 Prospect Avenue, PO Box 1, Osceola, Wisconsin 54020. 160 pages. U.S. $35.

Turtles provides a brief overview of the turtles of the world along with abundant colour photographs of many of the species. The book is divided into two parts. Part 1, the life and lifestyle of turtles, consists of three chapters. The first chapter covers the taxonomy and internal biology of turtles in roughly 10 pages. Chapter two, the ecology of turtles, covers topics such as thermoregulation, feeding, reproduction, and predators. The third chapter, covering the origin and fossil history of turtles, is only 3 pages long. Part 2, the diversity of modern chelonians, consists of two chapters. One chapter covers the families of Pleurodira, or side-necked turtles, and the other discusses the families of Cryptodira, or hidden-necked turtles. For each family account there is a map illustrating the global distribution of the family, then text discussing shared traits among members of the family and then information on many of the species within the family.

Roughly two-thirds of the books is allocated to Part 2, the family accounts. I found this an unsatisfactory balance. Part 1, which should provide a coherent picture of the various different turtle life history strategies, is just too short and superficial. Likewise, the family accounts remain superficial because they do not provide systematic species accounts. The information selected for individual species should highlight the unique qualities of that species, but all too often the species profiles rely on just some basic numbers (size, number of eggs laid), distribution (which countries it occurs in) and some general habitat info.

The text also has a number of glaring mistakes. In a text box on Linnaean taxonomy of turtles, the author states that turtles belong to the class Anapsida (page 14). In Linnaean terms, Anapsida is the subclass, while Reptilia (or Chelonia, for splitters) would be the class. The author claims that both McCord's Box Turtle (*Cuora mccordi*) and Zhou's Box Turtle *C. zhoui*) are believed to be extinct (pages 39-40), when really he should state they are likely extinct in the wild, as both species still occur in captivity. The author makes use of the most recent phylogenetic work on the genus *Clemmys*, by transfering the Wood Turtle (*Glyptemys insculpta*) to its new genus, but still leaves the Bog Turtle (*G. muhlenbergii*) in the genus *Clemmys*. Other careless errors include stating that there is more than one species within the genus *Actinemys* (page 98), and claiming that there are four species of Painted Turtle (*Chrysemys picta*; page 101), when really there are four subspecies. The Indian Flapshell Turtle (*Lissemys*

punctata) receives two different and somewhat contradictory species accounts, one brief account under its correct subfamily (Cyclanorbinae; page 134), and a longer account under an incorrect subfamily (Trionychinae; page 139). Despite these errors, there are some good things about this book. Part 1 does provide a very brief and readable introduction to the world of turtles. The photographs are generally quite good. Ultimately, however, this book could have been greatly improved by a thorough review from an expert on turtles.

DAVID SEBURN

Seburn Ecological Services, 2710 Clarenda Street, Ottawa, Ontario K2B 7S5 Canada

Whales and Seals Biology and Ecology

By Pierre-Henry Fontaine. 2007. Schiffer Publishing, 4880 Lower Valley Road, Atglen, Pennsylvania 19310 USA. 448 pages. U.S. $35. Paper.

During my career as a marine mammal research scientist I was reluctantly dragged in on several occasions to necropsy and dispose of large dead mammal carcasses found along the beaches of Canada's east or west coast. Almost always these mammoth mountains of mammalian flesh were in an advanced stage of putrefaction. Upon opening the body cavity one would confront what has been termed a "gaseous pudding" and it was challenging to properly identify even the most conspicuous organs. It is with this in mind that I say that I am impressed with the work in hand, which has yielded for the author a large amount of useful, detailed information, gathered with fortitude and persistence, from a source that many would have been wont to avoid.

The illustrations, particularly the excellent photographs of the organs and musculature, will serve as a valuable resource for field biologists learning their way around marine mammal carcasses. The author's expertise in marine mammals comes primarily from his extensive experience in performing necropsies of beach cast cetaceans and to a lesser extent pinnipeds. This book uses this as the point of departure relating the specific adaptations, the senses, nutrition, and locomotion, to the anatomical structures which he has studied and illustrated during his years of studies.

The remainder of the book attempts to give a general account of whales and seals, particularly from the North Atlantic, where the author has worked. The chapter on strandings is devoted to the question of why live cetaceans beach themselves. As the author points out, almost every imaginable reason has been offered from geomagnetic anomalies to suicide. The chapter leaves one hanging as do most articles on this subject. One very important recent work on this subject is the monograph *Marine Mammals Ashore* (J. R. Geraci and V. Loundsbury. 1993. Texas A&M Sea Grant Publication). This not mentioned by the author and would be a valuable source of additional information.

The chapter on mounting marine mammal skeletons will be found especially useful by museums and institutions wishing to do such displays. Little detailed information exists on this subject and the author has learned valuable lessons in avoiding errors in skeletal reconstruction from his numerous and careful field dissections.

The remaining chapters, while not based on the author's direct experience, are well researched and illustrated. The long association of people with whales and seals is presented in an interesting manner. Some specific examples of marine mammal hunting in the St. Lawrence are little known. The technique on Walrus hunting in the Magdalene Islands, which led to the early extinction of the southern-most Atlantic Walrus stock, is one such example.

The chapter dealing with the complicated subject of marine mammal paleontology gives a good introduction to a discipline which is both difficult to assimilate and where the information is not well organized in any single comprehensive source. This will serve as a good point of departure for students who want to learn more about the origins of marine mammals.

The last chapters, the fact sheets on Cetaceans and Pinnipeds, might be considered useful additions to this general work on marine mammals only because they include the species found in the North Atlantic, which is where most of the author's work has been done. One wonders why the author has included the Northern Elephant Seal (only found in the Pacific) and why the Pacific Walrus (*Odobenus divergens*) is mentioned and shown in one of the illustrations. The Arctic Ringed Seal, which is found as far south as the Labrador coast (Lake Melville) is omitted. A number of up-to-date field guides exist, which give a comprehensive account of the seals and whales in the North Atlantic and would serve their readers more effectively.

I recommend this book to the non-specialist who has an interest in whales in particular. It will also be a useful source of information for field biologists and naturalists who might deal with beach cast remains of marine mammals. It succeeds in what the author set out to accomplish by sharing his considerable knowledge of a subject, in which he has thoroughly immersed himself.

ENVIRONMENT

China Ecosystems

Sun Honglie, *Editor-in-chief.* 2005. The Science Press of China. 1823 pages. 350 Yuan RMB Cloth.

The publication of such a magnum opus can be regarded as a landmark achievement accomplished by this group of Chinese ecologists. The book summed up the main results of the long-term research on the ecosystem structure and function at more than 80 ecological research stations, extensively distributed over China, of the Chinese Academy of Science. The research comprehensively covered the various fields such as ecosystem classification, ecosystem structure and dynamics, ecosystem energy flow, water and nutrient cycling in ecosystems, ecosystem management and sustainable use and so on.

China is a vast territory, richly endowed by nature and abounding in diverse types of ecosystems. Traditional Chinese integrative philosophy, an abundance of resources and the fast increasing economic power confer on China satisfactory conditions and capacity for ecosystem research. However, in China, the initiation of ecosystem research was rather late compared with many other countries. At the beginning stage in the 1950s, ecosystem research in China was very rare and scattered. This was nearly stopped during the ten-year period of the Cultural Revolution. China began to participate in the large international ecosystem research plans, such as IBP [International Biological Program], MAB [Man and Biosphere Program], IGBP [International Geosphere-Biosphere Program], GTOS [Global Terrestrial Observation System], EHA [Ecosystem Health Assessment], PAGE [Pilot Analysis of Global Ecosystem] [Pesticide Assessment Guidelines?] and MA [Millennium Ecosystem Assessment] from the late 1970s. Driven by these international programs, Chinese ecosystem research developed quickly, especially in recent years.

Long-term observational studies play an irreplaceable role in understanding and assessing the ecosystem structure, function and their health status. In this course, the ecological research stations made great contributions. The Chinese ecological stations, which are distributed throughout the typical ecological zones of China, have accumulated long-term continuous and dynamic data, not only on the changes of the same ecosystem types under different driving forces, and on the integrated features of different types of ecosystems at the regional scale, but also on the long-term ecological experiments and management practices conducted in these stations.

Most of Chinese ecosystems were generally healthy in the past; however, in recent years, at least some of them have undergone serious degradation, and some are even close to irreversible damage. Not long ago, China Environmental Protection Administration announced the first Report on the Ecological Protection in China, which admits that the trend of environmental deterioration in China has not been effectively curbed yet, and more than 60% of lands are becoming environmentally fragile. Obviously, to achieve sustainable development, China must continually improve its deteriorating environment, maintain and continuously upgrade the capacity of its ecosystem service, which needs a sound understanding of the effective management of various types of ecosystems in China.

The results of the long-term research on the Chinese ecosystems were achieved with a background of large temporal and spatial environmental changes. Therefore, the data accumulated by the Chinese ecological research stations (data used in this book), include the information not only on the progressive but also degrading succession of Chinese ecosystems, and the summary of some restoration practices. These results are particularly unique and valuable, and could be used as references for some other regions and countries.

The objective of the Millennium Ecosystem Assessment of the UN, which involves a large number of ecologists from different regions and countries, is to systematically and comprehensively reveal the trends of changes of various ecosystems, and accordingly propose effective countermeasures for the future. *China ecosystems* is certainly helpful for such an assessment and its publication is timely.

The book is composed of eight parts. The first part is General review, including Chapter one: the history, evolution and perspective of the ecosystem research; Chapter two: the natural conditions for the formation of the Chinese ecosystems; Chapter three: the evolution of the Chinese ecosystems; Chapter four: the impacts of human activity on the ecosystems; Chapter five: the principles and the systems of the Chinese ecosystem classification.

The second part is Forest ecosystems, including Chapter one: introduction; Chapter two: cold-temperate zone northern conifer forest ecosystem; Chapter three: middle-temperate zone conifer-broad-leaved forest ecosystem; Chapter four: warm-temperate zone deciduous forest ecosystem; Chapter five: subtropical zone evergreen and deciduous broad-leaved mixed forest ecosystem; Chapter six: subtropical zone evergreen broad-leaved mixed forest ecosystem; Chapter seven: subtropical zone western mountainous region evergreen hard-and-broad-leaved forest ecosystem; Chapter eight: subtropical zone alpine conifer forest and mountainous region conifer-broad-leaved mixed forest ecosystem; Chapter nine: tropical zone seasonal rain forest ecosystem; Chapter ten: tropical zone rain forest ecosystem; Chapter eleven: sustainable development of China forest ecosystems.

The third part is Grassland ecosystems, including Chapter one: the formation and classification of the grassland ecosystems; Chapter two: temperate zone grassland ecosystems; Chapter three: high and cold region grassland ecosystems; Chapter four: warm-temperate zone grassland ecosystems; Chapter five: tropical zone grassland ecosystems.

The fourth part is China's water ecosystems, including Chapter one: introduction; Chapter two: fresh water ecosystems; Chapter three: lake ecosystems; Chapter four: the succession and primary productivity of the lake ecosystems; Chapter five: ocean ecosystems.

The fifth part is Farmland ecosystems, including Chapter one: introduction; Chapter two: northeastern Song-nen Plain farmland ecosystems; Chapter three: lower field of Liao River Plain farmland ecosystems; Chapter four: north China Taihang Piedmont Plain farmland ecosystems; Chapter five: Huang-huai Plain farmland ecosystems; Chapter six: Tai Lake Plain farmland ecosystems; Chapter seven: South China hilly region farmland ecosystems; Chapter eight: Dongting Lake Plain farmland ecosystems; Chapter nine: Central Sichuan hilly region farmland ecosystems; Chapter ten: Loess Plateau farmland ecosystems; Chapter eleven: oasis farmland ecosystems in desert regions.

The sixth part is nutrient cycling in terrestrial ecosystems, including Chapter one: a review on the research progress of biogeochemical cycling; Chapter two: cycling of carbon and main nutrient elements in farmland ecosystems; Chapter three: cycling of main nutrient elements in forest ecosystem; Chapter four: cycling of main nutrient elements in grassland ecosystems.

The seventh part is water cycling in terrestrial ecosystems, including Chapter one: introduction; Chapter two: water cycling in farmland ecosystems; Chapter three: water cycling in forest ecosystems; Chapter four: water cycling in grassland ecosystems.

The eighth part is the theories and methods for the ecosystem network research, including Chapter one: the purposes and tasks for the ecosystem network research; Chapter two: the establishment and development of the ecosystem network; Chapter three: the methods for the ecosystem network research; Chapter four: the scales for the ecosystem network research.

The book was well written with few errors. Abundant illustrations are helpful for readers to easily understand the research results. The book is suitable for the professionals who engage in ecology or environmental science, or other persons who are interested in these fields.

New Zealand – A Natural History

By Tui De Roy and Mark Jones. 2006. Firefly Books Ltd., Richmond Hill, Ontario. 160 pages. $40. Hardcover.

The authors, experienced professional photographers Tui De Roy and Mark Jones, moved to New Zealand about 16 years prior to the publication of the book, and, during this time, they explored many of New Zealand's distinct and often rugged and remote natural regions. The result of these explorations and hard work is this beautifully illustrated coffee table book containing more than 450 magnificent photographs which offer a wonderful introduction to many of the unique species and habitats of New Zealand. In keeping with one of the main areas of expertise of the authors – nature photography, the book is largely made up of beautiful pictures. Early in the book, there is a helpful map, which includes many of the locations and national parks referred to later on. The book also contains a reasonably detailed and useful index. As a biologist, I appreciated the inclusion – in an appendix just before the index – of a list of scientific and common names for many of the species named in the previous pages.

The text sections are fairly brief overall. I counted 39 pages covered mainly by text (not including the acknowledgments and index), out of the total 160 pages of the book. Thus, if one is planning a visit to New Zealand, reading the book prior to the departure may be easier than putting such a weighty, hardcover tome in the luggage.

Although brief, the text is not without merit. The authors have done their best to include information on a wide variety of animals and plants, as well as a few details about New Zealand's geological past and present. There are some interesting, although usually very short, stories about several species, including fist-sized giant carnivorous land snails – some of them endemic (restricted) to a single hill – that hunt large earthworms at night (some of the local earthworms can reach 1 meter in length) or the inquisitive kea, the very active mountain parrots of New Zealand, which are apparently capable of sometimes killing sheep and dismantling cars. There is a strong conservation theme throughout the book, and the main purpose of the text is clearly to highlight the plight of the many endangered species unique to New Zealand, and to discuss some of the conservation programs undertaken to save these rare species. This is a worthy goal, of course, and the authors' commitment to conservation is evident throughout.

However, as a scientist, I would have liked to see a more balanced and in-depth discussion of certain envi-

ronmental and conservation issues. The authors seem to take an uncritical approach towards some controversial control programs undertaken by the local Department of Conservation against species introduced to New Zealand by people, over the centuries. It is somewhat unsettling, for example, to read about the "Herculean aerial poisoning operation" – "the largest rodent control program ever undertaken anywhere in the world", on the same page where the authors refer to the "humane integrity" associated with the conservation initiatives such massive poisoning operations are a part of. It should perhaps have been mentioned, for example, that such massive poisoning operations can occasionally backfire, and affect rare native species as well. For instance, poisons used to eradicate mice also killed the North Island saddleback, a rare New Zealand native forest bird (Davidson and Armstrong 2002). Also, the magnitude of the effects of introduced herbivores on New Zealand's native plants can sometimes be difficult to determine (Veblen and Stewart 1982). In addition, it is worth noting that some species, such as the swallows and silvereyes mentioned by De Roy and Jones, expanded their ranges naturally into New Zealand in recent times. When it comes to the many interactions among introduced species and their new environments, the story is often considerably more complex than this book suggests. Thus, the repeated demonization of introduced species found in the text is often overly simplistic.

The authors often mention the negative impact of introduced wild mammals such as rats or Australian brush-tailed possums in New Zealand, but, curiously, seem to largely ignore the huge impact of New Zealand's domestic animals, particularly the country's enormous sheep population. According to Ponting (1993), there are more than 70 million sheep and 8 million cattle in New Zealand, and many of the habitats of this country have been changed drastically and irreversibly as a result. Also largely ignored in the book is a discussion of the early, pre-European, human-caused species extinctions. New Zealand's fauna used to be dominated by very large (the largest ones reached 3 meters in height) flightless birds called moa. These birds became extinct mainly due to overhunting by the Maori – the country's first human colonizers (Ellis 2004). The disappearance of the moas had important effects on some of the native plant species these giant birds were browsing on and had coevolved with. Thus, although conservation is, of course, a very important goal, it is also essential to recognize that nature is dynamic, and that the initial, pre-human colonization web of life found in New Zealand long ago can no longer be re-created due to the many irreversible changes that have taken place since then. A much more thorough and detailed discussion of New Zealand's prehistoric life and ecology can be found in the book by Worthy and Holdaway (2002).

Despite the shortcomings, the current work by De Roy and Jones represents a nice introduction to the unique natural world of this fascinating and remote country.

Beneath My Feet: The Memoirs of George Mercer Dawson

By Phil Jenkins. McClelland & Stewart, Toronto. 2007 Hardcover. 350 pages. 18 photographs, 6 sketches. $34.99.

Phil Jenkins set out to write the biography of George M. Dawson, the son of Sir John William Dawson, the first principal and then first president of McGill University. Jenkins has instead taken nearly 5000 of George Dawson's letters, most of them previously unpublished, from the McGill University archives, and has wisely allowed Dawson to write his own "autobiography." Jenkins has created an introduction in Dawson's style, has abridged an article published by Dawson in *Harper's Magazine*, and has written over 5% of the text (we don't know which segments) to fill in gaps not available in Dawson's own words. The result is a personal, frank, well-written, entertaining life of George M. Dawson, CMG, LLD.

A designer, "Mr. Richardson" (unaccountably, Jenkins does not provide his first name) has produced a charming book cover that fits perfectly with what would have been expected in the 1890s.

George M. Dawson was crippled in late childhood by spinal tuberculosis which left him a hunchback and a good foot shorter than he should have been. Nevertheless as an adult he struggled manfully through arduous hiking, canoeing and horseback riding that would have deterred many men of normal stature. He obtained superb training at the Royal School of Mines in London, England, where he was taught by Professor

Thomas Henry Huxley, a leading proponent of Darwin's theory of evolution. Young George was favourably inclined to Huxley's views and had spirited discussions on the subject with his father.

George M. Dawson was a geologist, author, teacher, civil servant, anthropologist, palaeontologist, surveyor, mapper, photographer, artist and poet. A number of his photographs, sketches, and poems are interspersed throughout this book. Although he was named geologist and naturalist to the North American Boundary Commission in 1873-74, his skills in natural history were weak (Jenkins fails to share this fact). In northern Montana, just south of the 49th parallel, he observed the last great herds of Bison and came across skeletons resulting from the slaughter of 21 plains Indians. Dawson named a number of geographic features in the Queen Charlotte Islands and the interior of British Columbia that are still in use today. He suffered the pain of unrequited love and remained a bachelor until his premature death from an acute chest infection at age 51.

I agree with Jenkins (page 2), that Dawson was "a writer ... of endearing wit, evocative description, and illuminating fact." He described an Orkneyman in the employ of the Hudson's Bay Company as "an amiable Hudson Bay Fossil." He used the term "liquid excisable articles" to describe spirituous liquors.

This book has not achieved its full potential. I spotted the following misspellings and factual errors, presumably made by Dawson and not by Jenkins: alumni (when alumnus was indicated), latitude (when longitude was meant), astrological (astronomical), peninsular (peninsula), tit bits (tid bits), 100th meridian (110th meridian), prairie chickens (Sharp-tailed Grouse), Dr Helckin (Dr Helmcken), F.R.C. (F.R.S.), silver load (silver lode), and Bearing Sea (Bering Sea). There is little doubt that a University press would have encouraged Jenkins to insert the correct spellings in square brackets, as well as to include an index, explanatory footnotes (e.g., to add the initials and explain the importance of Dr. W. F. Tolmie, surgeon to the Hudson's Bay Company), and a bibliography. The latter would have included *Life and Letters of George Mercer Dawson, 1849-1901*, by Lois Winslow-Spragge, Dawson's niece, and would have listed the available photocopies of Dawson's detailed field notebooks which Jenkins seems to have ignored. Similarly, we are not told that Sapper Duckworth was Dawson's collector and taxidermist in 1873-74, that white cranes were Whooping Cranes, that the blue jay was probably a Steller's Jay, that the hummingbird nest was likely that of a Rufous Hummingbird, and that the name of the destructive but now extinct Rocky Mountain Locust has since changed from *Caloptenus spretus* to *Melanoplus spretus*.

A longer introductory essay or a postscript could have allowed a more complete assessment of Dawson's great achievements which Dawson modestly did not mention. We learn, for example, that Dawson received an honorary doctorate from the University of Toronto, but those from Princeton, Queen's and McGill, and other high honors, are not mentioned.

In spite of the shortcomings mentioned, Dawson's skills make this book a treasure, a lasting contribution to Canadian history. I recommend it highly to the general public. It deserves a place in every university and high school library.

C. STUART HOUSTON

The Wolf Totem

By Jiang Rong. 2004. Changjiang Literary Art Press. Pages: 478; $18. Yuan RMB.

[*Editors note:* The Penguin Group, under the British Pearson Education Company, bought the copyright and will publish an English version in 2007. This researched-based novel has topped China's bestseller list for 16 straight months, selling about 1 million copies.]

The Chinese press has not published a significant book in many years. However, in April of 2004, the Changjiang Literary Art Press of China published the novel-style book *The Wolf Totem*, which was written by an author bearing the pseudonym Jiang Rong. The response from the media and the public was rapid and it became a best seller.

The book is composed of various relatively independent stories. The narration of each story is full of craftsmanship, firing one's imagination and stirring one's emotion. The novel-style book is a marvellous, unprecedented way to present many stories of the enigmatic animal of the steppe, the wolf. The stories are not only charming in their sense of humanity, but also colourful and valuable in their understanding of the ecological role played by the Wolf. After reading the book, readers will be enlightened, moved and even shocked by the vivid ecological ethics conveyed in the book. The publication of the book can be regarded as an important event for both literature and ecologists.

From the viewpoint of ecology, a steppe may be regarded as a special type of ecosystem seemingly simple in structure and function, but essentially diverse, complicated and unpredictable. From the perspective of humanity, a boundless steppe may be mysterious, thought inspiring and soul stirring, sometimes touching and sometimes plaintive. In the cultural evolutionary history of the world, the acted steppe as an endless wellspring of artistic creation and a boundless field for sci-

entific exploration. The anecdotes and the legends, the music and the paintings related to the steppe are uncountable; the study cases concerning the steppe ecosystem are also voluminous.

Turning aside from the fascinating visions and thrilling scenes the author describes in each story, and turning aside from the totem of wolf at the level of politics and humanities the author elucidates in his narration, the book is of important ecological values. The descriptions of the behaviours of the Wolf populations in teamwork, reconnaissance, ambuscade, and surprise attack, and the unusual wisdom exhibited in making use of weather and topography, as well as the discussions on the relationships among the populations of Wolf and human, sheep and grass can be regarded as very vivid and enlightening material. However, it is a pity that in an otherwise valuable book that the author does not give the basic scientific and quantitative relationships among the component populations of the ecosystem. This may be beyond the scope of this style of book.

All these mysterious stories took place in the steppes of northern China during a special period more than nearly 40 years ago when the author and his classmates as urban school graduates laboured in the countryside in response to the political call of Chairman Mao. At that time, the vast area of steppe of northern China had plenty of water and lush grass, creating a beautiful landscape. But afterward, due to overgrazing and farming, the steppe ecosystem degenerated rapidly.

China is the second largest country in the world in terms of the steppe area. However, due to the increase in large scale agriculture in the half century from 1949, 5% of the natural steppe area was turned into farmland [This constituted one fifth of the total farmland of China]. This has resulted in more than a quarter of Chinese land being threatened by desertification. More than 90% of the steppe has been degenerated and such degeneration is expanding at the rate of 2 million km^2/yr. Since steppe restoration is becoming harder and harder in China, all the stories about the steppe in the past are becoming almost unrepeatable. This further implicates the extreme rarity and the important value of the material in this book.

Ecosystems with multiple-trophic levels are complicated and maintaining the stability is critical. In a typical steppe ecosystem with three trophic levels: carnivore, herbivore and grass, the carnivore usually plays a top-down effect on the community structure, and by this means grass tends to be protected to some extent. The theory of trophic cascade and HSS hypothesis is useful in explaining, "Why the terrestrial world tended to be green." McLaren and Peterson (1994) used tree ring data to show how a top-down effect of Wolf populations on Isle Royale reduced Moose abundance resulting in an increase in the growth increment of forage trees. *The Wolf Totem* shows that in the northern China about one century ago, harmonious relationships among the component populations of the ecosystem did exist, and the relative stability of the pasture was naturally maintained. This supports the rationality of the theories as mentioned above. However, considering the present situations of the rapidly degenerated steppe ecosystem in northern China, the above-mentioned theories encounter limitations, because they do not deal with how and why "the terrestrial world turned from green to yellow or black" due to over-use and human disturbance. If a disturbance dimension was added to the theories and each dimension were given a threshold, the theories would become more general, compatible and extendable.

The Mongolians, the native people in the northern China, fully understood the natural laws of mutual restriction and dynamic balance among the population of wolf, sheep and grass in the steppe ecosystem in their long history dealing with nature, and knew how to efficiently live within these laws. They never killed all of the Wolves, never bred the sheep excessively and never over-grazed the pasture. The accumulation of such ecological wisdom imitating nature, acclimating nature and making use of nature, moulded the Mongolian nationality. On the contrary, by disobeying the laws of nature, they have unavoidably learnt a painful lesson about the degeneration of the steppe.

When human or social-economic dimensions are added into a natural ecosystem, it would become a social-economic-natural-complex-ecosystem (SENCE). The present steppe ecosystem in northern China is such a SENCE. Keeping such a SENCE developing in a harmonious way is a new challenge to China with ever-increasing population. The classical Chinese philosophy, such as *The Doctrine of the Mean*, emphasizes human's active roles such as participation, promotion, coordination and cultivation rather than domination, so as to reach harmony between human and nature. Combining the classical Chinese philosophy with the modern ecological theories and using the actual experiences and lessons for references, steppe-like SENCE would be managed more effectively. *The Wolf Totem* with its stories of a rural youth living among Inner Mongolian nomads and wolves tells of this grassland environment and nomadic culture. Reading *The Wolf Totem* will bring the reader a better understanding of the ecology of the Chinese-Mongolian steppe.

YOUNG NATURALISTS

Gracie. The Public Gardens Duck

By Judith Meyrick. Illustrations by Richard Rudnicki. 2007. Nimbus Publishing Limited. Halifax, Nova Scotia B3K 5MB Canada. 32 pages. $16.95. Cloth.

This is a delightful children's book, told from the perspective of Gracie the duck. The story is about the duck's quest for food crumbs in a public park near the CBC building in Halifax. Gracie spends most of her time, quite successfully, getting the attention of different people she sees in the park so that they will share their food with her.

However, one day, people are not giving food to her. "Mr. Black Suit", the person who usually feeds her, does not proffer up any of his muffin; nor does a pair of school girls, who actually apologize to Gracie. A young girl almost shares a piece of her peanut butter sandwich, until the girl's mother reminds her of the sign near the park entrance. What sign? What is going on? Gracie asks herself, puzzled about this change in her daily feeding regimen.

Finally, hungry Gracie reads some of the words on the sign and discovers that park policy has changed and feeding the ducks is no longer allowed. Gracie takes action, but even this doesn't work. The hungry duck is then forced to try the insects in the grass and then some plants in the pond, and finds that these are very satisfying. Pleased with herself, she now realizes that there is plenty of food in the park without relying on people for crumbs such as Mr. Black Suit – who comments to Gracie that she has adapted nicely.

The story is very compelling and suitable for ages 3 to 8 (at least) – my 12-year-old niece picked up the book and enjoyed it as much as her younger sisters did. The illustrations are dynamic and it is almost as if the people and ducks in this story are moving as you read it. Truly a delight – with a good lesson learned along the way.

Advice for Contributors to *The Canadian Field-Naturalist*

Content

The Canadian Field-Naturalist is a medium for the publication of scientific papers by amateur and professional naturalists or field biologists reporting observations and results of investigations in any field of natural history provided that they are original, significant, and relevant to Canada. All readers and other potential contributors are invited to submit for consideration their manuscripts meeting these criteria. The journal also publishes natural history news and comment items if judged by the Editor to be of interest to readers and subscribers, and book reviews. Please correspond with the Book Review Editor concerning suitability of manuscripts for this section. For further information consult: A Publication Policy for the Ottawa Field-Naturalists' Club, 1983. *The Canadian Field-Naturalist* 97(2): 231-234. Potential contributors who are neither members of *The Ottawa Field-Naturalists' Club* nor subscribers to *The Canadian Field-Naturalist* are encouraged to support the journal by becoming either members or subscribers.

Manuscripts

Please submit by post **to the Editor,** in either English or French, **three** complete manuscripts **written in the journal style.** Manuscripts may also be submitted (one copy) by e-mail. The research reported should be original. It is recommended that authors ask qualified persons to appraise the paper before it is submitted. All authors should have read and approved it. Institutional or contract approval for the publication of the data must have been obtained by the authors. Also authors are expected to have complied with all pertinent legislation regarding the study, disturbance, or collection of animals, plants or minerals. The place where voucher specimens have been deposited, and their catalogue numbers, should be given. Latitude and longitude should be included for all individual localities where collections or observations have been made.

Manuscripts should be printed on standard-size paper, **doublespaced throughout,** generous margins to allow for copy marking, and **each page numbered.** For Articles and Notes provide a bibliographic (citation) strip, an abstract, and a list of key words. Generally, words should not be abbreviated but use SI symbols for units of measure. The names of authors of scientific names may be omitted except in taxonomic manuscripts or other papers involving nomenclatural problems. "Standard" common names (with initial letters capitalized) should be used at least once for all species of higher animals and plants; all should also be identified by scientific name.

The names of journals in the Literature Cited should be written out in full. Unpublished reports and web documents should not be cited here but placed in a separate Documents Cited section. List the captions for figures numbered in arabic numerals and typed together on a separate page. Present the tables each titled, numbered consecutively in arabic numerals, and placed on a separate page. Mark in the margin of the text the places for the figures and tables.

Check recent issues (particularly Literature Cited) for journal format. Either "Canadian" or "American" spellings are acceptable in English but should be consistent within one manuscript. **The Oxford English Dictionary, Webster's New International Dictionary** and le **Grand Larousse Encyclopédique** are the authorities for spelling.

Illustrations

Photographs should have a glossy finish and show sharp contrasts. Electronic versions should be high resolution. Prepare line drawings with India ink on good quality paper and letter (don't type) descriptive matter. Photographic reproduction of line drawings should be **no larger than a standard page.** Write author's name, title of paper, and figure number on the lower left corner or on the back of each illustration.

Reviewing Policy

Manuscripts submitted to *The Canadian Field-Naturalist* are normally sent for evaluation to an Associate Editor (who reviews it or asks another qualified person to do so), and at least one other reviewer, who is a specialist in the field, chosen by the Editor. Authors are encouraged to suggest names of suitable referees. Reviewers are asked to give a general appraisal of the manuscript followed by specific comments and constructive recommendations. Almost all manuscripts accepted for publication have undergone revision—sometimes extensive revision and reappraisal. **The Editor makes the final decision** on whether a manuscript is acceptable for publication, and in so doing aims to maintain the scientific quality, content, overall high standards and consistency of style, of the joumal.

Special Charges — Please take note

Authors **must share in the cost of publication** by paying $90 for each page, plus $30 for each illustration (any size up to a full page), and up to $90 per page for tables (depending on size). Authors may also be charged for their changes in proofs. Reproduction of color photos is extremely expensive; price quotations may be obtained from the Editor.

Limited joumal funds are available to help offset publication charges to authors without grants or institutional support. Requests for financial assistance should be made to the Editor when the manuscript is submitted.

Reprints

An order form for the purchase of reprints or pdf will accompany the galley proofs sent to the authors. Invoices for publication costs will be sent when the submission is published.

The Ottawa Field-Naturalists' Club

FOUNDED IN 1879

Patrons

Her Excellency The Right Honourable Michaïlle Jean
Governor General of Canada

The objectives of this Club shall be to promote the appreciation, preservation and conservation of Canada's natural heritage; to encourage investigation and publish the results of research in all fields of natural history and to diffuse information on these fields as widely as possible; to support and cooperate with organizations engaged in preserving, maintaining or restoring environments of high quality for living things.

All manuscripts intended for publication except Book Reviews should be addressed to the Editor and sent by postal mail or e-mail.

Book-review correspondence should be sent by e-mail or postal mail to Roy John, Book-review Editor.

Subscriptions and Membership
Subscription rates for individuals are $33 per calendar year. Libraries and other institutions may subscribe at the rate of $50 pe year (volume). The Ottawa Field-Naturalists' Club annual membership fee of $33 (individual) $35 (family) $50 (sustaining) an $500 (life) includes a subscription to *The Canadian Field-Naturalist*. All foreign subscribers and members (including USA) mus add an additional $5.00 to cover postage. The club regional journal, *Trail & Landscape*, covers the Ottawa District and Loca Club events. It is mailed to Ottawa area members, and available to those outside Ottawa on request. It is available to Libraries a $33 per year. Subscriptions, applications for membership, notices of changes of address, and undeliverable copies should be maile to: The Ottawa Field-Naturalists Club, P.O. Box 35069, Westgate P.O. Ottawa, Canada K1Z 1A2. Canada Post Publication Mail Agreement number 40012317. Return Postage Guaranteed. Date of this issue: April–June 2007 (December 2007).

COVER: Four Maritime Garter Snakes, *Thamnophis sirtalis pallidulus*, observed in courtship behavior on the branches c Rhododendron shrub at 325 Prince Albert Road, Dartmouth, Nova Scotia, on 5 September 2006. See note by Gilhen an Strum pages 210-211.

Diversity and Distribution of the Terrestrial Mammals of the Yukon Territory: A Review

Brian G. Slough[1] and Thomas S. Jung[2]

Slough, Brian G., and Thomas S. Jung. 2007. Diversity and distribution of the terrestrial mammals of the Yukon Territory: A review. Canadian Field-Naturalist 121(2): 119-127.

The diversity and distribution of the terrestrial mammals of the Yukon has not been systematically reviewed since 1975, a time when the occurrences of many species were not well known. Since then, single species and community studies, biological collections and expert observations have increased our knowledge of the land mammals of the Yukon. Taxonomic studies have resulted in some additional species. We provide an update on the diversity and distribution of recent land mammals of the Yukon, including previously unreported range extensions, and include a revised checklist. Research in adjoining jurisdictions has contributed more hypothetical species for the Yukon. The mammalian fauna of the Yukon is in a relatively dynamic state, and human-induced changes, particularly climate warming, will undoubtedly influence mammalian diversity and distributions in the coming decades.

Key Words: biological diversity, Beringia, checklist, distribution, Mammalia, Yukon.

Philip Youngman (1975) provided the most comprehensive survey of the recent mammals of the Yukon. That information was based on a survey of observations and biological collections from the late 1800s to mid-1970s, and is now over 30 years old. A recent increase in interest in mammals, particularly non-harvested species, rare species, and species at risk, has resulted in new information and corrections to previously reported distributions. The evolution of the territorial wildlife management agency, the establishment of a conservation data centre, several university-based research projects (most notably near Kluane Lake; see Krebs et al. 2000), documentation of local and traditional knowledge, and a number of resident and visiting naturalists have all contributed much new information. Changes in taxonomy and nomenclature have also occurred since Youngman (1975), with the former particularly advanced with the use of phylogeographic analyses to differentiate taxa. DNA analyses have also helped detect the presence of cryptic species (e.g., *Myotis*, *Myodes*, and *Peromyscus* spp.) that are difficult to identify to the species level in the field. Herein, we provide an update of the terrestrial mammals of the Yukon Territory; an interesting zoogeographic area of Canada with both Beringian and post-glacial immigrant species from southern refugia.

Methods

We reviewed information from published and unpublished work, collections, and sightings made since Youngman (1975), primarily chronicling the period from the mid-1970s to the present. We identified and report on changes in species known to be present and update their distributions since Youngman (1975) and others (e.g., Banfield 1974; van Zyll de Jong 1983, 1985). Species without noteworthy changes are not discussed in our review; however, all documented species occurring in the Yukon are provided in a checklist (Table 1). Scientific names and English common names follow Wilson and Reeder (2005) except Caribou which replaces Reindeer. In addition, we have also extrapolated ranges of species found in neighboring jurisdictions to compile a list of hypothetical species. We did not consider the marine mammals of the Beaufort Sea.

Order Soricomorhpa (Insectivores)

Seven species of soricomorphs, representing one family (Soricidae), are recorded from the Yukon (van Zyll de Jong 1983; Table 1). Few surveys specifically for shrews have been undertaken in the Yukon and because they are most efficiently captured in pitfall traps (Prince 1941; MacLeod and Lethiecq 1963), they are likely undersampled using standard methods for small rodents (i.e., live-traps or snap-traps).

TABLE 1. Checklist of the terrestrial mammals of Yukon. Scientific and English common names follow Wilson and Reeder (2005).

Order / Family	Scientific Name	English Common Name
SORICOMORPHA		
Soricidae	*Sorex arcticus*	Arctic Shrew
	Sorex cinereus	Cinereus Shrew
	Sorex hoyi	American Pygmy Shrew
	Sorex monticolus	Dusky Shrew
	Sorex palustris	American Water Shrew
	Sorex tundrensis	Tundra Shrew
	Sorex ugyunak	Barren Ground Shrew
CHIROPTERA		
Vespertilionidae	*Eptesicus fuscus*	Big Brown Bat
	Myotis lucifugus	Little Brown Myotis
	Myotis septentrionalis	Northern Myotis
LAGOMORPHA		
Ochotonidae	*Ochotona collaris*	Collared Pika
Leporidae	*Lepus americanus*	Snowshoe Hare
RODENTIA		
Sciuridae	*Glaucomys sabrinus*	Northern Flying Squirrel
	Marmota caligata	Hoary Marmot
	Marmota monax	Woodchuck
	Spermophilus parryii	Arctic Ground Squirrel
	Tamias minimus	Least Chipmunk
	Tamiasciurus hudsonicus	Red Squirrel
Castoridae	*Castor canadensis*	American Beaver
Cricetidae	*Dicrostonyx groenlandicus*	Nearctic Collared Lemming
	Dicrostonyx nunatakensis	Ogilvie Mountains Collared Lemming
	Lemmus trimucronatus	Nearctic Brown Lemming
	Microtus longicaudus	Long-tailed Vole
	Microtus miurus	Singing Vole
	Microtus oeconomus	Root Vole
	Microtus pennsylvanicus	Meadow Vole
	Microtus xanthognathus	Taiga Vole
	Myodes gapperi	Southern Red-backed Vole
	Myodes rutilus	Northern Red-backed Vole
	Neotoma cinerea	Bushy-tailed Woodrat
	Ondatra zibethicus	Common Muskrat
	Peromyscus keeni	Northwestern Deermmouse
	Peromyscus maniculatus	North American Deermouse
	Phenacomys ungava	Eastern Heather Vole
	Synaptomys borealis	Northern Bog Lemming
Dipodidae	*Zapus hudsonius*	Meadow Jumping Mouse
	Zapus princeps	Western Jumping Mouse
Erethizontidae	*Erethizon dorsatum*	North American Porcupine
CARNIVORA		
Canidae	*Canis latrans*	Coyote
	Canis lupus	Wolf
	Vulpes lagopus	Arctic Fox
	Vulpes vulpes	Red Fox
Ursidae	*Ursus americanus*	American Black Bear
	Ursus arctos	Grizzly Bear
	Ursus maritimus	Polar Bear
Mustelidae	*Gulo gulo*	Wolverine
	Lontra canadensis	North American River Otter
	Martes americana	American Marten
	Martes pennanti	Fisher
	Mustela erminea	Ermine
	Mustela nivalis	Least Weasel
	Neovison vison	American Mink
Felidae	*Lynx canadensis*	Canadian Lynx
	Puma concolor	Cougar

TABLE 1. *(continued)*

Order / Family	Scientific Name	English Common Name
ARTIODACTYLA		
Cervidae	*Alces americanus*	Moose
	Cervus elaphus	Elk
	Odocoileus hemionus	Mule Deer
	Odocoileus virginianus	White-tailed Deer
	Rangifer tarandus	Caribou
Bovidae	*Bison bison*	American Bison
	Oreamnos americanus	Mountain Goat
	Ovibus moschatus	Muskox
	Ovis dalli	Dall's Sheep

Stewart et al. (2003) reported a specimen of Pygmy Shrew, *Sorex hoyi*, from the Ogilvie Mountains which would be a northern range extension; however the coordinates given for the specimen align with Dawson City (64°03'N, 139°25'W). Subsequently, a specimen was retained in 2005 from the Blackstone River in the Ogilvie Mountains (65°05'N, 138°11'W; Jung et al. 2007), representing a northern range extension of about 110 km.

The range of the American Water Shrew, *S. palustris*, has been extended northward since Youngman (1975) and van Zyll de Jong (1983) and it is now known to as far north as the Tombstone Range of the southern Ogilvie Mountains (Jarrell 1986; Cook et al. 1997). It has been observed near the tree line on Hamilton Creek, 30 km southeast of the Tombstone Campground (64°19'N, 137°38'W; J. Schou, personal communication).

The Tundra Shrew, *S. tundrensis*, is known from the northern Yukon south to Fortymile (64°26'N, 140°32'W Youngman 1975), where three additional specimens were obtained in 2003 (B. Slough and T. Jung, unpublished data). In the late 1970s five Tundra Shrews were trapped in alpine and subalpine habitats on the Haines Road in British Columbia within 20 km of the southwest Yukon, and about 500 km south of its previously known limits (Nagorsen and Jones 1981). It was thought to be limited to Beringia, a region unglaciated during the Wisconsin glaciation; however, the British Columbia locations are 500 km from the limits of Beringia and confound the expected distribution pattern (Nagorsen and Jones 1981). It may yet be found in the intervening area in the Yukon.

The Arctic Shrew, *S. arcticus*, remains known only from a single skull collected in 1965 (Youngman 1975), despite substantial subsequent survey effort for shrews (e.g., T. Jung and colleagues, unpublished data; J. Cook and colleagues, unpublished data). Further collections are required to assess its distribution in the Yukon.

Order Chiroptera (Bats)

Three species of bats, representing one family (Vespertilionidae), are reported from the Yukon (Table 1). Youngman (1975) reported only the Little Brown Myotis, *Myotis lucifugus*, from the Yukon, where it is widespread and common south of 64°N. Since Youngman (1975), the Northern Myotis, *M. septentrionalis*, has been confirmed (Jung et al. 2006a) and another species, either the Big Brown Bat (*Eptesicus fuscus*) or Silver-haired Bat (*Lasionycteris noctivagans*), has been recorded via acoustic sampling (B. Slough, unpublished data). Until recently, few mist-net or echolocation monitoring surveys for bats had been undertaken in the Yukon, and it is likely that the Order remains undersampled. Based on surveys in adjacent jurisdictions, there may be other species of bats present in the Yukon that are not yet documented.

The Northern Myotis, *M. septentrionalis*, was first found in the Yukon in 2004 when three individuals were captured at the La Biche River (60°08'N, 124°04'W; Jung et al. 2006a). Five additional specimens were captured in 2007 near Watson Lake (60°07'N, 128°49'W; Lausen et al. 2008). This species has also been captured at several locations in the Liard watershed of northern British Columbia (Wilkinson et al. 1995*; Bradbury et al. 1997*; Crampton et al. 1997*; Vonhof et al. 1997*; Vonhof and Wilkinson 1999*) and in the southern Northwest Territories as far west as Nahanni National Park (van Zyll de Jong 1985; Lausen 2006*).

Youngman (1975) had listed the Big Brown Bat, *E. fuscus*, as a hypothetical species for the Yukon based on a record from interior Alaska (Reeder 1965). In September 1999, B. Slough (unpublished data) made a recording of a bat echolocation call sequence with an AnaBat II bat detector (Titley Electronics, Ballina, New South Wales, Australia) at Morris Lake (60°25'N, 131°38'W) that was most likely *E. fuscus* (C. Corben, personal communication; Keinath 2004*). This is possibly the first record of the species from the Yukon, although it may be difficult to distinguish the echolocation calls of *E. fuscus* from those of Silver-haired Bats, as recorded with an AnaBat detector (Betts 1998). There is a single record from central Alaska (Reeder 1965) and unsubstantiated reports exist for southeast Alaska (MacDonald and Cook 1996). *E. fuscus* had been recorded on bat detectors in the Liard watershed in northern British Columbia (Wilkinson et al. 1995*;

Bradbury et al. 1997*; Crampton et al. 1997*) and southwestern Northwest Territories (Lausen 2006*).

Order Lagomorpha (Pikas and Hares)

As noted by Youngman (1975), two species of lagomorphs, representing two families (Ochotonidae and Leporidae) are recorded from the Yukon (Table 1).

The southeastern limit for the Collared Pika, *Ochotona collaris*, shown by Youngman (1975) was the Logan Mountains. It has since been sighted approximately 200 km east-southeast in the Kotaneelee (2004; 60°27'N, 124°12'W) and La Biche (1998; 60°14'N, 124°32'W) ranges (B. Bennett, personal communication).

Order Rodentia (Rodents)

There are 26 known species of rodents, representing five families (Sciuridae, 6 species; Castoridae, 1 species; Cricetidae, 16 species; Dipodidae, 2 species; Erithizontidae, 1 species), recorded from the Yukon (Table 1).

The Northern Flying Squirrel, *Glaucomys sabrinus*, occurs throughout the forests of the southern Yukon (Youngman 1975). It has been observed near the treeline on Hamilton Creek in the Ogilvie Mountains (64°20'N, 137°39'W; J. Schou, personal communication), confirming the northern range limit projected by Youngman (1975).

The Hoary Marmot, *Marmota caligata*, has been confirmed in the La Biche Range in the extreme southeast Yukon (60°14'N, 124°32'W; B. Bennett, personal communication).

The Woodchuck, *Marmota monax*, apparently has a broad range through the southern Yukon; however, sightings and specimens indicate a geographic separation of at least 370 km between the southern (Ross River; 61°59'N, 132°27'W) and central (Klondike; 63°39'N, 138°40'W) populations which Youngman (1975) shows as contiguous.

The Least Chipmunk, *Neotamias minimus*, was reported by Youngman (1975) at Bonnet Plume Lake. It has since been sighted approximately 100 km northwest on the Bonnet Plume River (seven locations from Bonnet Plume Lake to Fairchild Creek (64°58'N, 133°46'W; B. Slough, unpublished data) and approximately 80 km northwest on the Wind River (65°03'N, 134°54'W; S. Gilbert, personal communication). The species appears well distributed in the Wernecke Mountains.

The distribution of the Ogilvie Mountains Lemming, *Dicrostonyx nunatakensis*, is poorly understood, since it is known from only 13 specimens collected at Angelcomb Peak in the Ogilvie Mountains (64°36'N, 138°16'W; Youngman 1964, 1967, 1975), two of which were recorded recently (T. Jung and B. Slough, unpublished data).

Krebs and Wingate (1976, 1985) captured Nearctic Brown Lemmings, *Lemmus trimucronatus*, near the Alaska Highway south of Kluane Lake and from the Chilkat Pass, near the Haines Road, in British Columbia, extending its known range about 170 km southwest of that reported by Youngman (1975).

The Singing Vole, *Microtus miurus*, is known at present only from the British Mountains, the southern Ogilvie Mountains, and from the Kluane region of the southwestern Yukon (Youngman 1975; Krebs and Wingate 1976, 1985). Krebs and Wingate (1976, 1985) trapped extensively in the Kluane region and found the southern limit of distribution to be the Slims River area at the south end of Kluane Lake (61°N, 138°31'W). Nagorsen (2002) reported that it has not been found south to the British Columbia border as suggested by Banfield (1974) and Youngman (1975).

Jung et al. (2006b) reported the Southern Redbacked Vole, *Myodes gapperi*, from the Yukon at the La Biche River (60°08'N, 124°04'W). Youngman (1975) did not report *M. gapperi* from the Yukon; however, he considered *M. gapperi* and the Northern Red-backed Vole (*M. rutilus*) to be conspecific. Based on the distribution of *M. gapperi* in adjacent northeastern British Columbia and southwestern Northwest Territories (Banfield 1974; Nagorsen 2005) we suspect that *M. gapperi* may be more widespread in the Liard River watershed.

Youngman (1975) gave the northwestern limit of the Bushy-tailed Woodrat, *Neotoma cinerea*, as Kluane Lake. It has since been been observed on Ogilvie Island, Yukon River, near Youngman's projected northern limit (63°34'N, 139°44'W; B. Bennett, personal communication). In 2003, a nest of this species was observed at Bear Creek (64°02'N, 139°15'W; B. Slough, unpublished data), representing a 160 km northward range extension.

Muskrat, *Ondatra zibethicus*, inhabit wetlands across the territory (Youngman 1975). The northernmost observations were made in the Arctic wetlands of the Mackenzie Delta in the Yukon (68°46'N, 136°32'W; B. Slough, unpublished data).

The Northwestern Deermouse, *Peromyscus keeni*, had been confirmed through DNA analysis as being present in the Coast Mountains and adjacent areas of the southwestern Yukon (Wike 1998; Lucid and Cook 2004; M. Lucid, personal communication) within the range of the former *P. maniculatus algidus*.

In July 2005, a North American Deermouse, *P. maniculatus*, was captured in the Ogilvie Mountains (64°30'N, 138°13'W; T. Jung et al. unpublished data); representing a 70 km northward range extension, but within the range projected by Youngman (1975).

Interestingly, Lucid and Cook (2007) provide DNA evidence of an undescribed species of *Peromyscus* in southwestern Yukon. Wike (1998), working in central Yukon, also reported the possibility of an undescribed species of *Peromyscus* in the Yukon.

Banfield (1974) and Youngman (1975) show the Northern Bog Lemming, *Synaptomys borealis*, ranging throughout the Yukon north to the Porcupine River drainage. Smits et al. (1989) reported *S. borealis* teeth

and bone fragments in the scat of an Arctic Fox, *Vulpes lagopus*, collected in 1985, on Herschel Island, extending the range of *S. borealis* about 150 km north to the Beaufort Sea (69°35'N, 139°05'W).

The Western Jumping Mouse, *Zapus princeps*, is known from only two specimens collected in 1944 (Rand 1945; Youngman 1975) and another collected in 1980 (S. Beare, unpublished data); all three specimens are from the South Canol Road, near the Rose and Nisutlin rivers.

Order Carnivora (Carnivores)

Sixteen species of carnivores, representing four families (Canidae, 4 species; Ursidae, 3 species; Mustelidae, 7 species; Felidae, 2 species), are recorded from the Yukon (Table 1).

Coyotes, *Canis latrans*, expanded northward from 55°N to southern Alaska between 1829 and 1907 (Banfield 1974). The earliest reported sighting for the area is from "near Whitehorse, on the Alsek River Alaska, in February 1907" (J. A. Allen 1908, reported in Hall 1981). Cairnes (1909) reports the presence of Coyotes in the southern Yukon in 1908. The range has been represented as the entire Yukon (Banfield 1974; Youngman 1975); however, trapper and hunter returns and observations suggest that Coyotes are absent or scarce north of 65°N (Yukon Department of Environment, unpublished data). Extraordinary observations, such as a sighting at Old Crow (67°N, 135°W, C. P. Charlie reported in Youngman 1975) should be considered as extra-limital and not evidence of range expansion.

The Arctic Fox, occurs on the Yukon Coastal Plain and Herschel Island, roughly northward of the 150 m ASL contour (Smits and Slough 1993). There is no evidence of denning or other range use further inland, therefore extraordinary specimens from the Old Crow Flats and the Porcupine River (reported in Youngman 1975) should be considered as extra-limital and not evidence of range expansion. Similarly, extraordinary observations of Polar Bear, *Ursus maritimus*, near Old Crow (reported in Youngman 1975) should be considered as extra-limital and not evidence of range expansion. The Yukon range of Polar Bears is also restricted to the North Coastal Plain and Herschel Island.

An analysis of fur harvest data from registered traplines to 2006 shows that the Fisher, *Martes pennanti*, is largely confined to the Liard River watershed in the southeast Yukon, ranging west to the Teslin River (60°28'N, 133°18'W) as projected by Youngman (1975). Youngman's northern limit was approximately 61°N; however, the species ranges 80 km north to 61°40'N (upper Hyland River and Finlayson Lake; B. Slough and T. Jung, unpublished data). Several observations have been made west of the Teslin River, and Fishers have been trapped north of Whitehorse (Klusha Creek; 61°13'N, 135°58'W) and near Haines Junction (60°51'N, 137°36'W). We believe that the species is expanding its range northwards and westwards.

The Least Weasel, *Mustela nivalis*, occurs throughout the Yukon (Banfield 1974) and, contrary to Youngman (1975), it is present in the Liard watershed. Individuals have been captured by trappers in the Liard watershed (B. Slough, unpublished data; Yukon Department of Environment, unpublished data).

American Mink, *Mustela vison*, occurs throughout the Yukon, as far north as the Old Crow Flats (Youngman 1975) where it has been captured by trappers (Yukon Department of Environment, unpublished data) but does not appear to be a regular inhabitant north of the treeline (68°25'N; Bee and Hall 1956; Banfield 1974) as suggested by Youngman (1975).

Similarly, the North American River Otter, *Lontra canadensis*, occurs throughout the Yukon, as far north as the British and Richardson mountains (Youngman 1975), but does not likely inhabit the Arctic Coastal Plain (north of the 150 m ASL contour, Bee and Hall 1956; Banfield 1974) as suggested by Youngman (1975). We suggest that an observation from Herschel Island (Wildlife Management Advisory Council (North Slope) and the Aklavik Hunters and Trappers Committee 2003*) was an extra-limital movement. A similar occurrence was reported for the Beaufort Sea of northeastern Alaska by Haskell (2006). Additionally, we suggest that the Arctic range for Canadian Lynx, *Lynx canadensis*, shown by Youngman (1975) is extra-limital, and occurs only following years during a population crash.

The range of Cougar, *Puma concolor*, in the Yukon remains somewhat obscure, given the species' propensity for long-distance extra-limital movements. Sporadic sightings have occurred throughout the southern half of the territory. Although most sightings are unsubstantiated, they occasionally occur in concurrent geographic clusters and are often associated with the occurrence of Mule Deer, *Odocoileus hemionus*, (Yukon Department of Environment, unpublished data), providing some credibility to the sighting data. The first Yukon specimen was found dead at Watson Lake (60°04'N, 128°43'W) in November 2000 (Jung and Merchant 2005). Successful breeding by *P. concolor* in the Yukon has not been documented.

Order Artiodactyla (Even-toed Ungulates)

Ungulates have long been the management priority in the Yukon, and consequently the best known Order. Nine species of ungulates, representing two families (Cervidae, 5 species; Bovidae, 4 species), are recorded from the Yukon (Table 1). Since Youngman's (1975) review, White-tailed Deer, *Odocoileus virginianus*, have been recorded in the Yukon (Hoefs 2001).

Since Youngman (1975), introduced populations of Elk, *Cervus elaphus*, north and west of Whitehorse have grown substantially and now may number over 200 animals, although no reliable estimates are available. In addition to introduced populations, Elk have been reported regularly since 1977 in southeastern Yukon, primarily in the Hyland, Beaver, Coal, La-

Biche, and Liard river valleys (Hoefs et al. unpublished data*). The most recent reported location in southeast Yukon is from October 2004 at Beaver River, where the resident trapper has seen Elk with some regularity over the past several years (60°'N, 124°25'W; D. MacDonald, personal communication). Whether these animals in the southeast represent populations expanding their range northward from British Columbia (Shackleton 1999), or are extra-limital movements, is unknown.

Mule Deer, *Odocoileus hemionus*, appear to have extended their range in the Yukon since the review by Youngman (1975). They are now found throughout the Yukon, south of the Ogilvie Mountains (64°05'W) and including westward to Alaska (Hoefs 2001). Hoefs (2001) reported a 1998 observation north of the Ogilvie Mountains at Chapman Lake (64°50'N, 138°25'W). We regard this observation, however, as an extra-limital movement and not evidence of Mule Deer being distributed north of the Ogilvie Mountains.

Reliable observations of White-tailed Deer, *Odocoileus virginianus*, some including photographs, have been made in the Yukon (Hoefs 2001). The first observation was reported in 1975 near Tagish Lake (60°10'N, 134°20'W, Hoefs 2001). Mayo (63°05'N, 135°53'W) appears to be the most northern location that White-tailed Deer have been observed in the Yukon (M. O'Donoghue, personal communication). Hoefs (2001) reported an antlered skull found near Ross River (62°N, 132°25'W) as further evidence of White-tailed Deer in the Yukon.

American Bison (*Bison bison*) (Wood Bison subspecies, *B. b. athabascae*) have been reintroduced to the Yukon since the review by Youngman (1975). An attempt in 1951 to establish a small herd of Plains Bison, *B. b. bison*, in the Yukon, by releasing five animals from Alaska, had failed (Youngman 1975). Three Wood Bison herds may now be found in the Yukon; all are reintroduced. The Aishihik Herd ranges in southwestern Yukon, near Aishihik Lake (61°36'N, 137°30'W). Two other, smaller herds – the Nahanni and Nordquist herds – mainly range in the Northwest Territories and British Columbia; Shackleton 1999), respectively, but a portion of their annual range is in southeastern Yukon. The Nahanni Herd ranges into the LaBiche River valley (60°07'N, 124°03'W); the Nordquist Herd ranges along the Alaska Highway, north of Liard Hot Springs in British Columbia, and into the Yukon at Contact Creek (60°01'N, 127°37'W). Both of the southeastern herds were also reintroduced to their native range in the 1990s (Gates et al. 2000).

Muskox, *Ovibos moschatus*, were reintroduced to Barter Island (70°08'N, 143°38'W) and the adjacent mainland in northern Alaska in 1969 and 1970. Muskox were sighted almost yearly in the Yukon since the reintroduction but they did not appear to establish a year-round breeding population at the time of Youngman (1975). The first mixed sex groups including calves were reported in the Yukon in 1986 (D. Cooley, personal communication). They currently range as far east as the Blow River (ca. 137°W; D. Cooley, personal communication). Summer movements to the Old Crow Flats (ca. 68°N, 140°W) have been somewhat common since 1995. A new resident breeding population appears to have formed in the Richardson Mountains (ca. 68°N, 137°W) that remains all year in the mountains (D. Cooley, personal communication).

Hypothetical Species

The following species are found in neighbouring Alaska, British Columbia or the Northwest Territories, and their ranges may extend into the Yukon (Table 2). Some taxa, such as shrews and bats, are undersampled, as are some of the more remote geographic areas.

The Alaskan Tiny Shrew, *Sorex yukonicus*, likely occurs in the Yukon (Table 2), but has yet to be collected outside Alaska. This species has been recently described from seven specimens from Alaska in 1993 (Dokuchaev 1997). Subsequently, other specimens (ca. 30) have been obtained from Alaska as a result of directed pitfall trapping efforts (Peirce and Peirce 2000; MacDonald and Cook 2001*; Cook and MacDonald 2003*), indicating that the species is widespread, but uncommon, in Alaska. Specimens were obtained from Yukon-Charley Rivers National Preserve and Wrangell-St. Elias National Park and Preserve only 50 km and 12 km, respectively, from the western Yukon border (MacDonald and Cook 2001*; Cook and MacDonald 2003*). Directed sampling effort in 2003 near the abandoned village of Fortymile (64°25'N, 140°32'W) failed to secure a specimen (B. Slough and J. Jung, unpublished data).

Youngman (1975) noted the Long-legged Bat, *Myotis volans*, as a hypothetical species for the Yukon, based on a record near Atlin, British Columbia, reported by Swarth (1936). The species was recently captured in the southwestern Northwest Territories (Lausen 2006*). In addition to *M. volans*, we add the Western Long-eared Bat, *M. evotis*, and Silver-haired Bat, *Lasionycteris noctivagans*, to the list of hypothetical bat species in the Yukon. All three of these hypothetical species have recently been captured within 150 km of the Yukon border in northeastern British Columbia (see: Wilkinson et al. 1995*; Bradbury et al. 1997*; Crampton et al. 1997*; Vonhof et al. 1997*; Vonhof and Wilkinson 1999*; Lausen 2006*) and occur in southeast Alaska (Parker et al. 1997). These captures, however, have not been substantiated with a specimen, echolocation recording or a genetic sample (D. Nagorsen, personal communication). Acoustic records also exist for the Hoary Bat, *Lasiurus cinereus*, and the Eastern Red Bat, *L. borealis*, from the southwestern Northwest Territories (Lausen 2006*), suggestive that these species may also occur in southeastern Yukon. Parker and Cook (1996) reported Keen's Myotis, *Myotis keenii*, from southeastern Alaska (north to ca. 58°N), and it may yet be reported from in or near Kluane National Park Reserve in southwestern Yukon.

TABLE 2. Hypothetical terrestrial mammals that may occur in the Yukon.

Order / Family	Scientific Name	English Common Name
SORICOMORPHA		
Soricidae	*Sorex yukonicus*	Alaskan Tiny Shrew
CHIROPTERA		
Vespertilionidae	*Lasionycteris noctivagans*	Silver-haired Bat
	Lasiurus borealis	Eastern Red Bat
	Lasiurus cinereus	Hoary Bat
	Myotis evotis	Long-eared Myotis
	Myotis keenii	Keen's Myotis
	Myotis volans	Long-legged Myotis
LAGOMORPHA		
Leporidae	*Lepus arcticus*	Arctic Hare
	Lepus othus	Alaskan Hare
RODENTIA		
Sciuridae	*Marmota broweri*	Alaska Marmot
Muridae	*Mus musculus*	House Mouse
CARNIVORA		
Memphitidae	*Mephitis mephitis*	Striped Skunk

In addition to the resident Snowshoe Hare, *Lepus americanus*, Youngman noted the possibility of Arctic Hare, *L. arcticus*, or Alaskan Hare, *L. othus*, being found in northern Yukon. There is an unsubstantiated sight record of *L. arcticus* from the eastern Richardson Mountains of the Yukon in the 1970s (P. Frankish, personal communication).

The Alaska Marmot, *Marmota broweri*, may occur in the Yukon, but it has not yet been recorded from there. *M. broweri* is found as far east in Alaska as the Brooks Range in the Arctic National Wildlife Refuge (Bee and Hall 1956); it may also range in the British Mountains in Ivvavik National Park, Yukon. The Wildlife Management Advisory Council (North Slope) and the Aklavik Hunters and Trappers Committee (2003*) reports "two people said they remembered seeing (marmots) in 1960s and 1970s in the Babbage and Firth River areas".

The House Mouse, *Mus musculus*, occurred in the vicinities of Dawson and Whitehorse in the 1970s (Youngman 1975); however, no further specimens have been obtained. This species may be periodically introduced, but does not appear capable of sustaining commensal populations in the Yukon.

Banfield (1974) shows the Striped Skunk, *Mephitis mephitis*, entering the Yukon in the extreme southeast (La Biche River region) and coming very close in the Teslin area. It has not been documented from the Yukon with the nearest record being two skins taken at the junction of the Fort Nelson and Liard rivers in British Columbia (Rand 1944; Hatler et al. 2008), about 52 km SE of the Yukon. In the Northwest Territories, it is present at Fort Smith, and is expected at Fort Liard (S. Carrière, personal communication), the latter being only 30 km from the Yukon border.

Conclusions

Knowledge of the diversity and distribution of the terrestrial mammals of the Yukon has improved steadily since the last review was published in 1975 (Youngman 1975). Excluding Humans, there are now 63 species of terrestrial mammals that are believed to occur in the Yukon, representing 40 genera, 15 families and 6 orders (Table 1). There are an additional 11 hypothetical species (Table 2). All species, except *Mus musculus*, are native. Only one species, *Dicrostonyx nunatakensis*, is endemic. Populations of some species native to the Yukon have been introduced (*Cervus elaphus*) or reintroduced (*Martes americana*, *Oreamnos americanus*, *Bison bison*).

The mammalian fauna of the Yukon is in a relatively dynamic state. Several species have colonized the Yukon in the past 125 years (e.g., *Canis latrans*, *Odocoileus hemionus*, and *Puma concolor*). The history of mammal colonization and evolution in Yukon and neighbouring Alaska have been discussed by Youngman (1975) and MacDonald and Cook (1996). Approximately one-third of the recent terrestrial mammals of the Yukon originated in Beringia; the remainder are southern immigrants (Youngman 1975). Many of the southern immigrants have limited distributions in the Yukon today. For example, the newly recorded bat species are likely southern immigrants, and Chiropterans may still be colonizing northwestern North America (Jung et al. 2006a). *Myodes gapperi* and *Peromyscus keeni* are similarly southern immigrants. Further cryptic species may be present in the Yukon, for example, in the genus *Peromyscus* (Lucid and Cook 2007) and *Myotis* (Jung et al. 2006a). Human-induced changes, particularly climate change, will undoubtedly affect mammalian diversity and distributions, particularly in

northern regions (e.g., Humphries et al. 2002, 2004). Ranges of some species in the Yukon will likely grow with anthropogenic habitat changes and climate warming (e.g., Mule Deer), while others may contract (e.g., Caribou). Detailed mapping of distribution in the Yukon can assist in monitoring any change in distributional patterns.

Appropriate sampling techniques for species typically undersampled, such as echolocation monitoring and mist-netting for bats and pitfall trapping of shrews, has rapidly increased our knowledge of these secretive and cryptic species in the Yukon. Sampling in remote areas not well surveyed for mammals will also likely yield interesting records. Further mammal surveys, particularly for the smaller species (<1 kg) and in geographic areas with inadequate sampling, will continue to improve our understanding of Yukon mammals. Such knowledge is imperative for the conservation of biodiversity and predicting the impact of climate change and landscape change on the diversity, distribution and conservation status of Yukon's mammals.

Acknowledgments

We thank the numerous individuals and agencies that contributed species-specific information, including collections and observations, or funding, that substantially improved our knowledge of the diversity, distribution and status of terrestrial mammals of the Yukon. Financial support was provided by the Yukon Department of Environment and the Northern Research Institute, Yukon College. David Nagorsen and an anonymous referee reviewed an earlier version of the manuscript.

State Records and Habitat of Clam Shrimp, *Caenestheriella gynecia* (Crustacea: Conchostraca), in New York and New Jersey

Robert E. Schmidt[1] and Erik Kiviat

Hudsonia Limited, P.O. Box 5000, Annandale, New York 12504 USA

Schmidt, Robert E., and Erik Kiviat. 2007. State records and habitat of Clam Shrimp, *Caenestheriella gynecia* (Crustacea: Conchostraca), in New York and New Jersey. Canadian Field-Naturalist 121(2): 128-132.

We report new records of the Clam Shrimp, *Caenestheriella gynecia* Mattox 1950, from three localities in the Hudson Valley of New York and one locality in northeastern New Jersey. All of our specimens were collected in puddles on dirt roads. The New Jersey specimens have meristics that are well within the range of *Caenestheriella* Daday 1915; however, the eastern New York specimens resemble those reported from Massachusetts with meristics that are closer to *Cyzicus* Audouin 1837. We hypothesize that *C. gynecia* was established as a parthenogenetic species due to an unlikely dispersal event in the western part of its range and has migrated eastward since the last glacial maximum. Dispersal of this species may occur by wind, in the gut of birds, or stuck to animal feet or fur, or to vehicles. We recommend that *C. gynecia* be treated as rare and vulnerable to extinction throughout its range unless demonstrated otherwise.

Key Words: Clam Shrimp, *Caenestheriella gynecia*, temporary pond, biogeography, dirt road, New York, New Jersey.

Clam Shrimps are small freshwater bivalvular arthropods in the order Conchostraca. Clam Shrimps inhabit isolated ephemeral pools, temporary ponds, and sometimes lakes; the taxon is found nearly worldwide (Williams 1987). *Caenestheriella gynecia* Mattox 1950 is a parthenogenetic species with no records of males, although males can be uncommon in related species and may be discovered (see Eder et al. 2000). Until Smith and Gola (2001) reported two populations of this species from western Massachusetts, the known range extended east from Ohio (Smith 2001) to northeastern Pennsylvania. Here we report four localities of *C. gynecia* in the eastern United States, representing range extensions to New York and New Jersey.

Methods

Specimens were captured from rain puddles and preserved in 50% isopropanol. Preserved specimens were measured with digital calipers (greatest length in mm). Spines on the telson and second antennal segments were counted at 320× with a stereomicroscope.

Results

Here we document four collections of *Caenestheriella gynecia*, representing the first records of this species from New Jersey and New York.

New Jersey: rain puddles on unimproved Paterson Lateral Gas Pipeline road between Empire Avenue and the New Jersey Turnpike, Borough of Carlstadt and Township of South Hackensack, Bergen County, 74°02'26"W longitude, 40°49'37"N latitude, Hackensack Meadowlands. [Weehawken, New Jersey–New York. 1967, U.S. Geological Survey (USGS) 7.5 minute topographic map sheet], *E. Kiviat*, 2 September 2001. 6 specimens (Kiviat and MacDonald 2004).

New York: rain puddle on abandoned farm road, 3.5 km south of Rhinebeck, Dutchess County, 73°55'15"W longitude, 41°53'19"N latitude, Town of Rhinebeck, [Kingston East, New York. 1963, photorevised 1980 USGS 7.5 minute topographic map sheet], *S. Nyman*, 27 May 1994. 1 specimen, 7.6 mm, dried (Site C-3 in Kiviat et al. 1994*).

New York: rain puddles on dirt road, ca. 1.4 km NNW of East Park, Dutchess County, 73°55'20"W longitude, 41°48'19"N latitude, Town of Hyde Park, [Hyde Park, New York. 1963, USGS 7.5 minute topographic map sheet] *E. Kiviat & J. Bridges*, 26 June 2002. 5 specimens.

New York: rain puddles on ATV trail, ca. 3.4 km NNE of Saugerties, Greene County, 73°55'58"W longitude, 42°06'33"N latitude, Bristol Beach State Park [Saugerties, New York. 1963, USGS 7.5 minute topographic map sheet], *E. Kiviat,* 25 July 2007. 1 specimen.

Clam Shrimp habitats (Figure 1) at the New York and New Jersey localities were all rain puddles on dirt roads. Clam Shrimp were observed swimming slowly on the underside of the surface film in New Jersey, and swimming in the water column and along the bottom in New York. The puddles were ca. 1.5-30 m^2 and ca. 5-15 cm deep at the dates of collection. The rain puddles essentially lacked vascular plants. We have visited the puddles at the New Jersey locality several times at different seasons 2002-2007; some of the puddles maintained their depths even during dry periods, but did dry during the summer 2005 drought. The New Jersey puddles were consistently very turbid and Clam Shrimp were not visible below the surface; the Hyde Park pools were clear enough to see Clam Shrimp swimming along the bottom. The roads at the New Jersey and Saugerties, New York localities are regularly used by all-terrain

FIGURE 1. Habitat of *Caenestheriella gynecia* in New Jersey. Photograph by Erik Kiviat.

vehicles (including "four-wheelers" and motorcycles), and road vehicles (pickup trucks and sport-utility vehicles) were observed using the road at the Hyde Park locality. The puddles at the Bristol Beach State Park site were created and maintained by all-terrain vehicle use. We believe the puddle habitats at these four sites were created and maintained by wheeled vehicles; the puddles at the Rhinebeck locality appeared less recently disturbed and may have been created by farm vehicles. The dirt road at the Hyde Park locality was bordered by hardwood forest and woodland pools. The dirt road at the Rhinebeck locality was fringed by tall shrubs and small trees in the midst of a wet meadow and old field. In New Jersey, the dirt road was fringed by Common Reed (*Phragmites australis*), tall shrubs, and small trees, and was raised ca. 1.5 m above the level of extensive, formerly tidal, marsh now dominated by common reed. The ATV trail at the Bristol Beach site was bordered by second-growth hardwood forest.

The Hyde Park and Rhinebeck roads appear to comprise *in situ* soil materials which are mapped as Nassau-Cardigan complex (Lithic and Typic Dystrochrepts) and Sun silt loam on glacial till, and Hudson-Vergennes soil (Glossaquic Hapludalf) on glaciolacustrine silty clay, respectively (Faber 2002*). The Saugerties site has soils mapped as Hudson silt loam, a Glassaquic Hapludalf and Madalin silty clay loam, a Mollic Ochraqualf according to Tormes (1979*).

The pH of these soils varies from strongly or very strongly acidic at the surface to moderately akaline in the substratum (Faber 2002*). Wetlands adjoining the New Jersey site were mapped as Sulfhemists and Sulfaquents (Goodman 1995*); however, the dirt road appears to have been constructed from imported material with a light reddish color that may have originated from nearby red Triassic shale and sandstone (Schuberth 1968). We have not found Clam Shrimp in wetlands adjoining the dirt road habitats.

Smith and Gola (2001) discussed generic placement of this species and showed that the meristics on their Massachusetts specimens were not typical of *Caenestheriella* but were intermediate or closer to species of *Cyzicus* Andouin 1837. The most significant difference in the genera is the shape of the male rostrum which cannot be determined in our specimens. There are differences in the number of spines on the telson, but the counts on the Massachusetts specimens overlapped the genera and Smith and Gola (2001) questioned whether the two genera were distinct. The size and meristics of our New Jersey specimens (Table 1) fall clearly within *Caenestheriella* Daday 1915 (all specimens contained eggs) as did the single specimen from Saugerties (west of the Hudson River). Our New York specimens from east of the Hudson River, however, are similar to those in western Massachusetts. It is possible that the eastern New York and Massachusetts populations are *Cyzicus*.

Discussion

Caenestheriella gynecia inhabits temporary freshwater pools and was considered a "warm water" species

TABLE 1. Size and meristics of *Caenestheriella gynecia* (Clam Shrimp) specimens from New Jersey and New York.

State	Number of specimens	Mean (range) size, mm	Number of telson spines	Number of segments, 2nd antennae
New Jersey	6	4.75 (4.2-5.2)	18-22	15-19
New York	5	9.10 (8.6-10.2)	27-32	15-20

by Weeks and Marcus (1997). This is typical habitat for a suite of clam shrimp and relatives (Anostraca, Notostraca) and for certain distantly related species of Cladocera and Ostracoda (Williams 1987). The diversity of aquatic animals in a given pool is low, however, probably due to the habitat's inherent instability and simplicity. *Caenestheriella gynecia* appears to be different from its close and distant relatives in that it is known mostly from rain puddles on dirt roads; the type locality (Mattox 1950), a second location in Ohio (Emberton 1980), one of the populations in Massachusetts (Smith and Gola 2001), and this paper. Although the puddles in which we found *C. gynecia* are more-or-less permanent, their small size (and high turbidity in the case of the New Jersey pools) may exclude some aquatic predators much as does impermanence.

Wiggins et al. (1980) and Williams (1985) characterized the resident biota of ephemeral aquatic habitats as having high fecundity, short life spans, and rapid maturation. Additionally Clam Shrimp produce "resting eggs" (Hann 1996*) which can tolerate heat, cold, and dessication and may require freezing or drying to hatch (Mattox and Velardo 1950; Belk and Belk 1975).

Hann (1996*) observed that the small scale distribution of *Caenestheriella setosa* was patchy, with some puddles inhabited while nearby puddles were empty. This suggests that, despite the Clam Shrimp's investment in large numbers of resting eggs, egg survival is low, even short-distance dispersal is difficult, or local extinction (in a pool) is frequent. Boileau and Taylor (1994) showed that related organisms had poor dispersal over even very short distances and calculated that there were 0.6-4.5 dispersers per generation in small pools in South Carolina. We presume that dispersal of Clam Shrimp is primarily in the resting egg stage and we can envision several modes of dispersal of these eggs.

Eggs of *C. gynecia* from desiccated puddles could be blown along with soil particles from one puddle or locality to another. Animals passing through puddles, especially species that spend time in muddy habitats, could pick up eggs in mud adhering to their feet, shells, or fur. Potential vectors of dispersal include Raccoons (*Procyon lotor*, see Maguire 1963), Mallards (*Anas platyrhynchos*), Snapping Turtles (*Chelydra serpentina*), and humans. More recently, human traffic in the form of wheeled or tracked vehicles could act as a dispersal agent.

Although our few specimens of *C. gynecia* do little to establish a pattern that would resolve the taxonomic question posed by Smith and Gola (2001), there is a geographic pattern that deserves discussion. All known localities for this species are within the maximum extent of the Wisconsinan glaciation (Figure 2) except one location in central Ohio (Emberton 1980). It is, of course, possible that not all populations of this species have been documented (especially since we are here reporting several) and that there may be populations to the south of the known distribution. This is important because robust biogeographic hypotheses do require accurate knowledge of an animal's distribution. Although this species is rare, there are a number of researchers actively working with Clam Shrimp in the midwestern and southern United States and there have been no other reports of this species.

This distribution suggests the following hypotheses. *Caenestheriella gynecia* is derived from a sexually reproducing species, probably *C. setosa*, whose range is closest to *C. gynecia*. Dispersal into the glaciated area occurred in the Ohio Valley and was an unlikely event given the dispersal mechanisms of the species. Unlikely dispersal would favor establishment of a parthenogenetic individual over at least two sexually reproducing ones. This scenario suggests that *C. gynecia* is relatively young, less than 12 500 years old (the approximate age of the last glacial retreat).

Dispersal eastward from the Ohio Valley would be equally unlikely except that seasonally muddy dirt roads were created soon after European colonization of the northeastern states. *Caenestheriella gynecia* could have spread as eggs in mud splattered on wagons or horses' hoofs and its distribution would follow traffic flow. Recently, many of these colonial roads have been paved, leaving *C. gynecia* to persist in the remaining dirt road habitats, including farm roads, logging roads, and service roads for powerlines and pipelines.

The above scenario could be corroborated by phylogenetic and genetic analyses. The closest living relative of *C. gynecia* should be geographically very close to *C. gynecia* but we are unaware of any phylogenetic analyses of this genus. Additionally, the genetic variation in *C. gynecia* should be minimal because it is parthenogenetic, has been derived from a very small founder population, and is geologically young.

Caenestheriella gynecia or its ancestors could have evolved in association with American Bison (*Bison bison*), living in "buffalo wallows" and dispersing in mud caked on Bison fur or hoofs. Butler (1995) noted buffalo wallows somewhat larger than the puddles where we collected *C. gynecia* and alluded to observations of mud stuck to fur. Dispersal of resting stages in the guts of birds is also possible for *C. gynecia*. Proctor et al. (1967) found that *Artemia* eggs and the eggs and adults of Ostracoda could remain viable after passing through the gut of Killdeer (*Charadrius vociferus*).

FIGURE 2. Map of the eastern United States showing collection localities of *Caenestheriella gynecia* in relation to the southern extent of the most recent glaciation.

Long distance (1400 km) dispersal of *Caenestheriella belfragei* was presumed due to eggs being carried on or in waterfowl (Donald 1989). Proctor (1954) showed that viable eggs of some phyllopods could pass through the gut of ducks. If *C. gynecia* had been carried to the glaciated areas by waterfowl, its close relatives could be anywhere along the waterfowl flyways.

Two of the New York and the New Jersey Clam Shrimp localities are privately owned. The Hyde Park road is part of a residential subdivision and reportedly has been excavated for installation of a water pipeline. The New Jersey road is subject to gas pipeline maintenance activities and adjoins The Richard P. Kane Natural Area, possibly subject to habitat restoration. Because field surveys have not been conducted to determine the distribution of, and degree of threat to, *C. gynecia* populations in the northeastern states, we recommend this species be treated as rare and vulnerable to extinction unless demonstrated otherwise. Only 11 localities (Figure 2) have been reported for *C. gynecia*, including our localities, although a recent Ohio survey listed just one site (Weeks and Marcus 1997). If this Clam Shrimp were reviewed by state Natural Heritage Programs in New York and New Jersey it would be ranked as G2, S1 assuming all the reported sites are extant. We recommend that dirt roads one year or more old with long-lasting rain puddles > 1 m^2 and > 5 cm deep be checked for Clam Shrimp during June-September as part of land management or environmental review processes. Clam Shrimp may sometimes be observed swimming in the pools and may be captured by sweeping a fine-mesh dipnet through the pools.

Research, conservation, management, and restoration of biodiversity are most often done in wildlands and natural areas. Yet urban, industrial, and other altered landscapes are expanding rapidly in North America. Certain rare or declining native species survive or even thrive in human-altered landscapes. Examples of rare species occupying human-disturbed soils are: Knieskern's Beaked Rush (*Rhynchospora knieskernii*) in a tire rut and on a waste dump in the New Jersey Pine Barrens (Schuyler 1999) and larvae of the Regal Fritillary (*Speyeria idalia*) overwintering in soils disturbed by tanks in Pennsylvania (Rosenzweig 2003). These ecological distributions can be the result of human activities creating a surrogate habitat type or physical-chemical environment not otherwise available, an abundance of food, reduced predation or competition, or persistence during landscape change (see, e.g., Adams 1994). It can be said that "Biodiversity is where you find it." Therefore conservation biologists and environmental planners need to pay more attention to organisms such as *Caenestheriella gynecia* and the artificial or altered habitats that support them. Altered or artificial habitats of types known to support rare organisms should be surveyed for those species routinely, much as natural and semi-natural habitats are surveyed for rare species. Those sites discovered to support a rare

species, such as the Clam Shrimp sites reported here, should be considered for conservation management. In the case of *Caenestheriella gynecia*, management may need to include a degree of controlled motor vehicle activity or its equivalent to maintain the puddle habitat and potentially disperse Clam Shrimp among puddles. We recommend that this species be considered rare and vulnerable to extinction throughout its range unless demonstrated otherwise.

Colonization of Non-Traditional Range in Dispersing Elk, *Cervus elaphus nelsoni*, Populations

Fred Van Dyke

Montana Department of Fish, Wildlife and Parks, Red Lodge, Montana 59068, USA
Present address: Department of Biology, Wheaton College, Wheaton, Illinois 60187 USA; e-mail: fred.g.vandyke@wheaton.edu

Van Dyke, Fred. 2007. Colonization of non-traditional range in dispersing Elk, *Cervus elaphus nelsoni*, populations. Canadian Field-Naturalist 121(2): 133-141.

As ungulate populations increase in density on traditional range, resulting increases in intraspecific competition can encourage dispersal of some individuals to new areas. Such areas, although lower in density of conspecifics, might present unfamiliar arrays and types of habitat that could require altered patterns of home range and habitat use by dispersers. However, the specific adaptations employed by dispersers in such circumstances are not well documented or understood. I investigated three cases of range expansion by Elk (*Cervus elaphus nelsoni*) populations experiencing population growth on traditional ranges in south-central Montana, USA. Each source population produced a group that dispersed to non-traditional areas. Compared to source populations, dispersing groups increased average size of home ranges, changed patterns of use in core areas of home ranges, and used habitats differently than Elk on traditional range. Dispersing groups demonstrated fidelity to new ranges equal to that of source populations, but their seasonal tenure on non-traditional range was strongly linked to environmental conditions, especially rainfall. Dispersal of groups increased the overall range of the population and its range of habitat use. In growing populations of Elk, managers should determine if dispersing groups exist and whether they should be protected to establish new populations in marginal areas or be reduced to limit potential Elk-landowner conflicts.

Key Words: Elk, *Cervus elaphus*, dispersal, habitat use, population, Montana.

On traditional ranges, animals typically concentrate use in the most productive patches of habitat (Charnov 1976; Parker and Stuart 1976). However, intraspecific population pressure, often associated with population growth, can cause a species to increase its range of habitat use in less predictable ways (Rosenzweig 1991). For non-territorial species, the tendency to increase range of habitat use with increasing population density has been formalized as the Ideal Free Distribution (IFD) Theorem. The Ideal Free Distribution Theorem asserts that individuals choose habitats at densities associated with equal levels of fitness (Fretwell and Lucas 1970). Thus, IFD predicts that when populations occupy new ranges at low densities, individuals will occupy only optimal habitat. As density increases, so does interference with conspecifics, causing individual fitness to decline. Individuals leave optimal habitat when fitness drops below what they could achieve in a suboptimal habitat at a lower population density.

Among ungulates, the behavior of Elk (*Cervus elaphus nelsoni*) in populations experiencing long-term population growth corresponds to predictions of IFD. Dispersive behavior associated with population growth and an increasing range of habitat use might contribute to the initial stages of colonization and the establishment of a permanent population in a previously unoccupied area (Safriel and Ritte 1983). The colonization of vacant habitat without decreased fitness of colonists is an alternative to increased intraspecific competition on traditional range. Although the IFD Theorem makes density-dependent dispersal theoretically plausible, such dispersal has been difficult to demonstrate in ungulates (Clutton-Brock et al. 1985; Boyce 1989), and determination of the mechanisms of colonization by individuals dispersing from established ungulate populations, or their relation to population growth, has been problematic.

In three increasing populations in south-central Montana, USA, Elk demonstrated changes in habitat use and home-range characteristics, increasing spatial separation of adjacent populations, and fissioning of individual populations into multiple populations (Van Dyke and Klein 1996; Van Dyke et al. 1998), all of which can lead to an increasing range of habitat use. The last response, population fissioning, was initiated by the formation of a dispersing group that made seasonal movements to new range, often containing a distribution of vegetation communities different from the traditional range of the established population. In investigating the role of such groups in expanding range and habitat use of established populations, I sought to determine what changes dispersing Elk make in their use of home range and habitats compared to their populations of origin that might enable them to persist on new ranges that the established population did not use.

Study Area

Three populations of Elk in south-central Montana (USA) were investigated, locally known as the Line Creek (LC), Picket Pin (PP), and Silver Run (SR) populations (Van Dyke and Klein 1996; Van Dyke et al. 1998).

These populations summer in the Absaroka-Beartooth Wilderness Area and winter in lower elevation foothills and prairies on the Custer National Forest and adjoining private land (Figure 1).

Climate in this area was characterized by long, cold winters and short, cool summers during the study period. Mean January and July temperatures at the Mystic Lake, Montana, reporting station (elevation 2339 m) near the approximate center of the study area were -4.1 and 17.1°C, respectively. Average annual rainfall and snowfall reported at the same location were 64.7 and 497.9 cm, respectively (NOAA 1992).

Forests were dominated, from lowest to highest elevations, by Limberpine (*Pinus flexilis*), Lodgepole Pine (*P. contorta*), Douglas Fir (*Pseudotsuga menziesii*), Engelmann Spruce (*Picea engelmannii*), and Whitebarked Pine (*Pinus albicaulis*). Non-forested communities at lower elevations were dominated by Bunchgrass (*Pseudoroegneria spicata*)-forb and sagebrush (*Artemisia* spp.) associations. Alpine areas were dominated by sedges (*Carex* spp.), cottongrass (*Eriophorum* spp.), Alpine Bluegrass (*Poa alpina*), and various alpine forbs. Detailed descriptions of these plant communities are provided in Van Dyke et al. (1991) and Van Dyke et al. (1994).

Methods

Sampling Procedures

Thirty-five female Elk were captured and radio-collared in January-March 1988 (19), December and February 1989 (11), March 1990 (1), and March 1991 (4). All but three were captured by darting from a helicopter (Nielson and Shaw 1967) with Carfentanil (dosage 0.0082 mg/kg). Two Elk were captured in baited traps and one Elk by a net-gun fired from a helicopter. All were fitted with telemetry collars (AVM Instrument Co., Telonics, Inc.). Procedures associated with locating individual animals have been described (Van Dyke and Klein 1996; Van Dyke et al. 1998).

Detection of Dispersing Groups

I documented movements of small groups (≤40 individuals) away from source populations (120-160 individuals) through relocations of ≥1 radio-collared Elk in each group. Such groups used different ranges and remained isolated from individuals in the source populations for 6-9 months each year. One group separated from each source population. These were the Trout Creek (TC) group from the PP population, the Hellroaring (HR) group from the SR population, and the Wolf Creek (WC) group from the LC population.

The relationship of dispersing groups to source populations, as well as the boundaries of seasonal ranges of the dispersing groups, was unknown prior to the study. As a result, individuals in dispersing groups were unintentionally collared when they were near source populations on winter range. Although only a small number of Elk were radio-collared in each group, the percentages of radio-collared Elk in such groups were ≥ those collared in source populations (5-12% vs. 4-6%, respectively). Given the sociability of Elk, previous studies have been successful in tracking large groups even when only one radio-collared animal was present (e.g., Craighead et al. 1973), and that also was the case in this study. Locations of radio-collared individuals were considered representative of the entire group because: (1) dispersing groups contained few (7-40) individuals; (2) dispersing groups remained constant in size during occupancy on non-traditional range, indicating that groups possessed a high degree of cohesiveness; and (3) radio-collared individuals always were present in the group when they were located.

Estimation and Analysis of Home Range Characteristics

Home range of each population or group was defined as the 95% contour minimum convex polygon (MCP) area and associated activity centers of source populations and dispersing groups as computed by HOME RANGE, a home range analysis program (Ackerman et al. 1990). To estimate seasonal home ranges, seasons were defined as winter-spring (1 December – 31 May) and summer-autumn (1 June – 30 November). Seasons were combined in this manner because source populations had substantial overlap between winter and spring ranges and between summer and autumn ranges (Van Dyke and Klein 1996; Van Dyke et al. 1998).

Because MCPs are sensitive to sample size, I evaluated only populations with ≥ 21 locations/season for calculation of seasonal range and ≥ 45 total locations for calculation of annual range. All samples were equal to or larger (seasonal $\bar{x}$ = 97, range 21-438; annual $\bar{x}$ = 189, range 45-787) than these minimums. Previous tests of the relation between numbers of locations and home area estimates indicate that such sample sizes estimated ≥ 81% of population home ranges for ungulates in this area (Van Dyke et al. 1995; Van Dyke et al. 1998). Core areas within home ranges (Kaufman 1962) were identified by comparing actual range use distributions generated from harmonic mean estimates of home range (Dixon and Chapman 1980) to hypothetical uniform use distributions (Samuel et al. 1985). I also determined the percent contribution of core areas to total home areas and core area percent contribution to total use, and then determined the ratio of use contribution to area contribution as an index of the concentration of use in core areas.

Evaluation of Range Use

Home areas of dispersing groups and source populations were compared in four ways. First, as a first approximation of potential movement differences in landscape pattern and scale, I compared distances Elk in dispersing groups moved from winter to spring or summer ranges with the same movements in their associated traditional populations using linear, straight-line distances between seasonal geometric activity centers in each group as determined by pooled locations from 1988-1992. I compared distances associ-

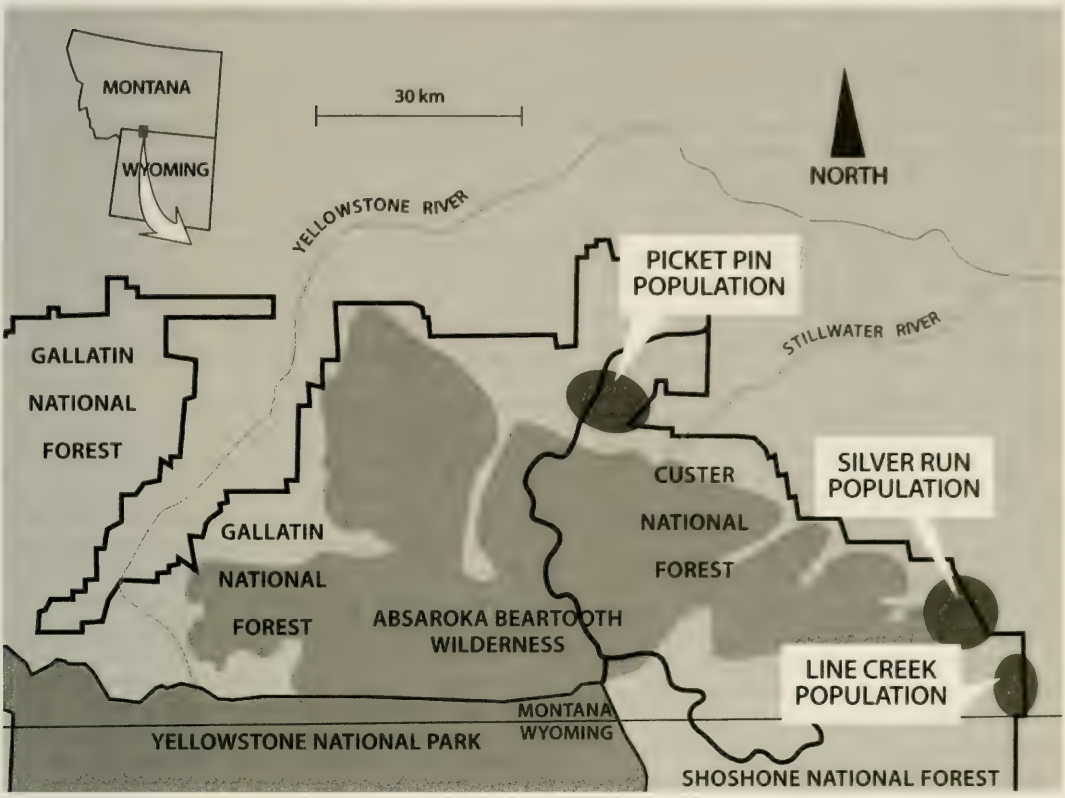

FIGURE 1. Study area and approximate ranges of the Line Creek, Picket Pin, and Silver Run populations of Elk in south-central Montana, USA, 1988-1991.

ated with such movements to the radius of the shared winter home area as an index of relative movement scale. Second, I compared home range size between source populations and dispersing groups using 2-sample *t*-tests. Third, I evaluated Euclidean distances between points in associated dispersing group and source populations through a multiple range permutation procedures test, which evaluates whether distributions of distances in different groups come from a common probability distribution (Mielke et al. 1976). Fourth, I compared use-area ratios of core areas between dispersing groups and associated source populations to determine if differences existed in degree of concentration of core area use using a 2-sample *t*-test. The ratio of core to non-core use is important because core areas would be likely to include the most optimal habitat within a home range. Therefore I treated the concentration of use in core areas as an index of relative differences between optimal and suboptimal habitats within a home range.

Use of Vegetation Communities and Production of Forage

The types of vegetation communities present on all seasonal ranges of all populations varied, but were simplified for analysis to categories of alpine, grass-forb (meadows), Douglas Fir, Limberpine, Lodgepole Pine, sagebrush, Spruce (subalpine forest), and Whitebark Pine. Together, these vegetation communities covered the range of elevations used by all populations in all seasons as well as broadly covering the array of vegetation communities encountered and used by Elk. Comparisons of use of vegetation communities by Elk in source populations, based on locations of animals, to availability of such communities visually identified at 568 randomly selected points within home areas of such populations were evaluated using the Design I version of Manly et al. (2002) resource selection function (RSF) model. This version of the RSF model, which uses independently sampled counts of available and used resources, assumes that the availability of vegetation communities does not change over the course of the study period, that vegetation communities were correctly identified, and that Elk had free and equal access to all vegetation communities within their designated ranges, assumptions that were met in this study. The model's null hypothesis that Elk select vegetation communities in proportion to their occurrence was tested by comparing use to availability via a Chi-square goodness of fit test (Manly et al. 2002). The application of this procedure to similar tests for random selection of

each vegetation community was adjusted using Bonferroni corrections to prevent error accumulation. I used Manly's standardized selection ratio to represent relative strength of selection for a given vegetation community. Vegetation communities with 0 availability in a given range were omitted from analysis.

Locations of Elk during 1988-1991 were used to determine core foraging areas of dispersing groups on summer ranges. Using radio telemetry locations and visual observation, I established five 404-m^2 (20.1 m × 20.1 m) macroplots selected within core foraging areas determined in each dispersing group and in the core foraging area of the PP population in 1991. Ten macroplots already had been established in core foraging areas of LC and SR populations (five in each area) as part of another study (Van Dyke et al. 1994). I compared volumes of forbs and graminoids produced from each core area associated with dispersing groups to core areas of respective source populations through 2-sample *t*-tests. Sampling methods have been described (Van Dyke et al. 1991, 1994). Shrubs were not included in the analysis because shrub coverage was low on most plots and summer diets of Elk in all populations averaged <10% shrubs (Van Dyke et al. 1994). Although species-specific forage selection was evident (Van Dyke et al. 1994), all available graminoids and forbs were consumed. Thus, estimates of forb and graminoid volume were considered to represent volume of edible browse.

Results

Seasonal dispersal and home range characteristics

All dispersing groups moved greater absolute and relative distances from winter to spring or summer ranges than traditional populations, and, in two of three cases, traveled in entirely different directions and followed different elevational gradients (Table 1). Relative to the size of winter home areas, traditional populations migrated distances 2.3-7.5× the radius of their winter home areas to reach spring and summer ranges, but dispersing groups moved 5.6-11.0× the radius of their winter home areas to reach new, non-traditional ranges in the same seasons.

Elk in dispersing groups used annual or seasonal ranges differently than Elk in associated source populations (Table 2). Differences also existed in home range sizes of dispersing groups and source populations (Figure 2). The annual and seasonal home ranges of Elk in the TC and WC groups were larger than home ranges of Elk in associated source populations. In contrast, seasonal home ranges of Elk in the HR group were similar to those estimated for individuals in the associated source population. Differences between source and dispersing group populations also were evident in use of core areas (Figure 3). Hellroaring Elk made greater use of smaller areas (higher use/area ratios) in summer and autumn than did Elk in their source (SR) population. A similar trend was evident in the more concentrated use of winter and spring core areas by the WC group. In contrast, the TC group demonstrated more dispersed range use than its source (PP) population, and had no identifiable core area in winter-spring (use/area ratio = 1).

Patterns of habitat and elevation use in source populations: Comparisons of source populations and dispersing groups

No population showed random proportional selection of vegetation communities ($P < 0.001$, all cases), but selection patterns differed in different populations, and, in two of three cases, patterns of selection in source populations differed from selection patterns in associated dispersing groups. The SR source population and HR dispersing group were the only source population-dispersing group pair in which selection of vegetation communities did not differ. Both used alpine areas less frequently than expected and used Lodgepole Pine communities more than expected (Table 3). The Line Creek source population and its associated WC dispersing group differed in selection patterns in four of seven vegetation communities (Table 4), and the PP source population and its TC dispersing group in four of eight (Table 5), although patterns were different in each case. Wolf Creek Elk used sagebrush communities most commonly in the spring, followed by an intensive shift to alpine communities in the summer, resulting in nearly equal rates of use in these communities over the combined period. However, WC Elk did not use any one vegetation community differently than expected, although their overall pattern of use was different from availability. In contrast, LC Elk made more equitable use of all available vegetation types, although they were most commonly located in stands of Limberpine (33%). Line Creek Elk used grass-forb and Limberpine communities more than expected, and sagebrush and alpine communities less than expected. Actual proportional use in grassland-forb communities was identical in the two populations. Observed differences in significance in this case were attributable to differences in the number of observations in the two groups.

The majority of PP Elk locations were in grass-forb vegetation (56%), and this population used this vegetation type and Limberpine at greater than expected frequencies. Picket Pin Elk used Lodgepole Pine less than expected. In contrast, TC Elk were most commonly located in stands of Douglas Fir (42%). They used this vegetation community more than expected, but used spruce-dominated vegetation less than expected.

Core foraging areas of dispersing groups and source populations differed in volumes of forbs and graminoids produced (Table 6). Trout Creek core areas had higher volumes of graminoids and forbs compared to PP core areas, but differences in other comparisons displayed no consistent pattern.

Two dispersing groups, TC and WC, showed different patterns in seasonal elevational use compared to their source populations (Figure 4). Trout Creek

TABLE 1. Scale considerations in distance, direction, and elevational differences in pairs of traditional source populations and dispersing groups of Elk in south-central Montana, U.S.A., 1988-1991. In each pair, the traditional source population is listed first. Migration distance (km) reflects distance from shared winter range activity center to traditional source population or dispersing group spring or summer range. Home range radii estimated as square root of home range area (km²) divided by π.

Population	Migration distance	Migration direction	Elevation change	Population home range radius – winter
Line Creek	4.9	W	Higher	2.12
Wolf Creek	11.8	NE	Lower	
Picket Pin	11.6	W	Higher	1.54
Trout Creek	17.0	NE	Same	
Silver Run	11.8	SW	Higher	1.70
Hellroaring	14.6	SW	Higher	

TABLE 2. Results of Multiple Range Permutation Procedures analysis comparing range utilization between dispersing groups and associated source populations in south-central Montana 1988-1991. $P < 0.05$ interpreted as evidence of significantly different distributions between dispersing group and associated source population. n = number of Elk locations used in analysis (source population and dispersing group, respectively). Seasons selected represent periods of movement to new ranges by dispersing groups.

Population	Season	n	Standardized test statistic	P
Picket Pin-Trout Creek	Annual	348/71	-102.89	<0.0001
Silver Run-Hellroaring	Summer-Autumn	291/58	- 46.24	<0.0001
Line Creek-Wolf Creek	Spring-Summer	263/73	- 10.99	<0.0001

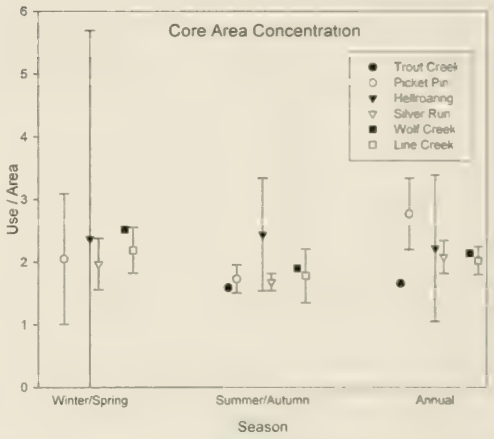

FIGURE 3. Core area concentration indices (% use of core area/% contribution of core area to home area) of source populations and associated dispersing groups of Elk in south-central Montana, USA, 1988-1991. Bars indicate 95% CI.

Elk used lower elevations in summer ($t_{123} = 3.62$, $P < 0.0001$), consistent with their tendency to move to traditional, high elevation summer range later than PP Elk. Similarly, WC Elk used lower elevations in summer ($t_{212} = 2.03$, $P = 0.05$) and autumn ($t_{157} = 2.46$, $P = 0.02$), reflecting their tendency to spend at least part of these periods off the Line Creek Plateau and away from the main LC population. Hellroaring Elk used elevations similar to SR Elk in all seasons, had non-overlapping ranges in summer and autumn, and persisted on their new ranges throughout both seasons in all years. In contrast, TC and WC Elk always abandoned the non-traditional ranges at some point during the summer.

Over time, it became apparent that dispersing groups abandoned non-traditional ranges more quickly in drier years. I examined the strength of this relationship at the conclusion of the study through a logistic regression analysis relating June and July rainfall (estimated

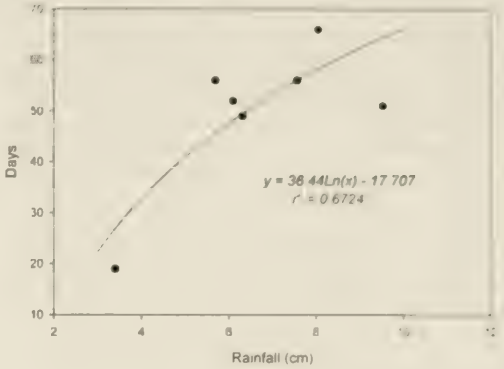

FIGURE 5. Relation between June and July rainfall (combined) and estimated number of days on non-traditional summer range in the Trout Creek and Wolf Creek dispersing groups in south-central Montana, USA, 1988-1991.

from the Red Lodge, Montana recording station for WC Elk and the Nye, Montana recording station for TC Elk, NOAA 1992) to the total estimated number of days in June, July, and August on new range. Variation in combined June and July rainfall explained two-thirds ($r^2 = 0.67$, $P < 0.0001$) of the variation in days on non-traditional summer range in the TC and WC groups (Figure 5).

Discussion

Dispersal and density of populations

Historical expansion and contraction of ranges of ungulate species has been influenced by many factors, both natural and anthropogenic (Laliberte and Ripple 2004), but range expansions at local levels are often achieved by dispersal, which in turn may be mediated by density (Andersen et al. 2004). An ecological correlate of a population's capacity to colonize new range is its ability to yield a large colonizing group (Safriel and Ritte 1983), something which can be best achieved during periods of population growth. In this area, annual aerial counts indicated that all source populations experienced population growth on traditional range in the decade prior to this study. From 1979 to 1988, the PP population increased from 44 to 190 individuals (355%), the SR population from 72 to 139 individuals (93%), and the LC population from 85 to 127 individuals (49%) (Van Dyke et al. 1998), and all populations continued to increase through 1991. These increases are small relative to fluctuations in historically large populations of Elk like the nearby Northern Yellowstone Population which has ranged from 10 000 to 20 000 individuals in recent years (Committee on Ungulate Management in Yellowstone National Park US National Research Council 2002). Nevertheless, such increases were proportionately large relative to past population size and occurred on very small annual ranges (84 – 166 km^2) (Van Dyke et al. 1998) compared to those of the Northern Yellowstone Population, whose annual range encompasses thousands of km^2 (Committee on Ungulate Management in Yellowstone National Park U.S. National Research Council 2002). Thus, it is reasonable to believe that the numerical increases observed in these herds on these restricted ranges would increase densities and competition for space and other resources, contributing to the formation of dispersing groups, although the dispersive behavior seen in these small populations might be very different from that observed in larger populations.

Size of home range and use and productivity of vegetation communities

Variability in use and selection patterns of vegetation communities in different populations is, in part, evidence of the behavioral plasticity of Elk. As these populations experienced relatively large proportional increases, the movement and fidelity of colonists to new ranges appeared similar to observed seasonal movements of White-tailed Deer (*Odocoileus virginianus*) in areas fragmented by agriculture (Nixon et al. 1991). However, whereas deer occupied traditional vegetation communities in the new areas to which they dispersed, Elk in these dispersing groups demonstrated their plasticity in habitat selection by changing their patterns of use of vegetation communities as they moved to new ranges.

It is not only the proportion of a vegetation community in the landscape that determines its use by Elk, but also its juxtaposition and interspersion with other such communities (Porter and Church 1987), a dimension of availability that was beyond the scope of this study to measure. Thus, use of vegetation communities by specific populations would be a poor guide for landscape scale habitat management. In these populations Elk adjusted use of vegetation communities according to local and seasonal availabilities.

Use of marginal habitats is associated with increased rates of range expansion in some ungulate species (Andersen et al. 2004). The larger home ranges of TC and WC groups using non-traditional lower elevation ranges in summer might indicate the same trend. Further, larger home ranges in these groups also suggested that forage on non-traditional ranges might have been more dispersed. However, comparisons of forage volume in core foraging areas of group and source populations did not support the premise that productivity was lower in ranges of dispersing groups. On the TC range, forage volume was higher in both graminoids and forbs. However, foraging areas for TC Elk were concentrated in riparian areas and probably could not support higher densities or more extended use by Elk in most years. Nutritional quality of vegetation is often better at higher elevations (Johnston et al. 1968; Boyce 1989), a trend confirmed on these ranges in measurements of protein and other nutrients in low vs. high-elevation plants (Van Dyke et al. 1991; Van Dyke et al. 1994). However, McCorquodale (1991) found that, in sagebrush habitats used by Elk in central Washington similar to those used by the WC group, low intercommunity variability in forage production, lack of a nonforage overstory, and the relative abundance of foraging areas all mitigated against lower primary production.

The low-elevation, mostly treeless habitat of the WC group appeared to provide the greatest potential for heat stress of Elk during summer months because of its absence of thermal cover. However, Peek et al. (1982) have argued that thermal cover is not a requirement for Elk. Elk historically occurred on the Great Plains and in other areas that lacked thermal cover. Loss of Elk in these areas was due to human influence, not lack of adaptability to the habitat (Laliberte and Ripple 2004). In recent years Elk have recolonized areas in treeless, sagebrush-steppe habitats in central Washington (Rickard et al. 1977; McCorquodale et al. 1986; McCorquodale 1991) similar to those used by the WC Elk.

Both source populations and dispersing groups demonstrated fidelity to their selected home ranges from year to year. Such fidelity suggested that dispersing groups had already established some degree of tradition in their use of new ranges and were not dispersing randomly. However, early abandonment of non-traditional range at low elevations under drier conditions suggested that such new ranges might have been sub-optimal environments for Elk compared to traditional range. Dispersing groups responded to periods of environmental stress by rejoining source populations on traditional areas. By doing so, individuals in dispersing groups might have benefited from the source population's collective knowledge of available resources on traditional range and its successful, long-term strategies of range use (Edge et al. 1985).

Management Implications

Elk in dispersing groups demonstrated an ability to locate and adapt to non-traditional range through various combinations of altered habitat use, changes in patterns of seasonal elevational migration and adjustments in home range size and use. Given this repertoire of adaptive strategies, managers should assume that areas adjacent to existing Elk populations but presently without Elk could be colonized, and could be of importance to future growth of such populations and expansion of their range. For example, in restorations of Elk in Kentucky (USA), translocated Elk demonstrated fidelity to a variety of habitat types, including some not previously encountered on their original ranges (Larkin et al. 2004). Such considerations are of importance to managers as efforts to restore Elk populations in several U. S. states (Didier and Porter 1999; McClafferty and Parkhurst 2001; Larkin et al. 2004) are being considered or have commenced.

As noted previously, dispersing groups from these smaller populations might not exhibit the same patterns or behaviors associated with dispersal as has been observed in historically large herds. Thus, it would be advisable to consider and evaluate dispersive behavior associated with populations of different sizes before making broad generalizations about patterns of dispersive behavior that could apply to populations of all sizes. However, even with this caveat in hand, it will be true that expanding ranges and growing populations of Elk, regardless of size, might create added opportunity to view and hunt Elk, but such expansion could contribute to increasing conflict between Elk and other land uses such as agriculture and must be examined in a regional context. Where colonization of new range by Elk enhances the persistence of marginal populations and provides desired recreational opportunities for hunting and viewing Elk, managers should identify, provide access to, and, if possible, acquire adjacent range to which individuals might disperse, especially within the broader context of regional strategies that follow the principle of retaining large contiguous or connected areas that contain critical habitats (Dale et al. 2000). In these cases, dispersing groups should be protected from disturbance until they have established fidelity to new ranges (Larkin et al. 2004). Where dispersion to adjacent, but non-traditional ranges and habitats is likely to create or exacerbate land use conflicts between Elk and humans, managers should consider lowering densities of Elk on traditional range to reduce the likelihood of such dispersal.

Wilkinson, Shannon F., Patrick T. Gregory, Christian Engelstoft, and Kari J. Nelson. 2007. The Rumsfeld paradigm: knowns and unknowns in characterizing habitats used by the endangered Sharp-tailed Snake, *Contia tenuis*, in southwestern British Columbia. Canadian Field-Naturalist 121(2): 142-149.

The Sharp-tailed Snake, *Contia tenuis*, has a small and highly fragmented range in British Columbia, where it is considered endangered. Known sites are few in number and generally small in spatial extent; numbers of snakes apparently are correspondingly low. Furthermore, most known sites for the species are on private lands in areas that are fairly heavily developed or being developed. Thus, the species is under serious threat of habitat alteration or loss. Although land stewardship has been a valuable conservation tool in this case, we also need to identify the key habitat requirements of Sharp-tailed Snakes to identify potential new sites, modify former or potential ones, or even create new ones. In this study, we compared sites known to harbour Sharp-tailed Snakes with those that seemed subjectively similar and therefore potentially suitable. We also compared these known and potential sites with randomly chosen nearby locations. Variability of most measured features was high, both within and among site/location categories. Nonetheless, we found significant differences between known and potential sites and between those locations and random ones. Overall, locations known to be used by snakes had a more southerly aspect, more rock cover, shallower soil and litter, and less shrub cover than other sites. This study was constrained by the small number of known sites for Sharp-tailed Snakes in southwestern British Columbia, making our conclusions suggestive rather than definitive. Future work should incorporate additional variables. It also might be useful to undertake comparative habitat studies elsewhere in the range of the Sharp-tailed Snake where it is more common.

Key Words: Sharp-tailed Snake, *Contia tenuis*, habitat, British Columbia.

On 12 February 2002, U.S. Secretary of Defense Donald Rumsfeld made the following widely cited observation:

"As we know, there are known knowns; there are things we know we know. We also know there are known unknowns; that is to say, we know there are some things we do not know. But there are also unknown unknowns, the ones we don't know we don't know. And if one looks throughout the history of our country and other free countries, it is the latter category that tend to be the difficult ones."

Although Rumsfeld was not discussing science, his circumlocutional comments nonetheless may well be apt in science (Shermer 2005). In conservation biology, the unknowns, whether known or unknown, usually exceed the known knowns and we often have to make educated guesses in, for example, trying to determine where there might be additional suitable habitats for a threatened or endangered species.

To manage and conserve any species, it is crucial to understand its habitat requirements. The fitness of any species should be greatest in a habitat for which it is best suited and that it presumably prefers (Garshelis 2000). Determining critical habitats is an important component of the background knowledge that allows researchers and managers to develop strategies to either recover or maintain an endangered or threatened species and to choose areas in which to explore such strategies.

The Sharp-tailed Snake (*Contia tenius*) is a small secretive snake, from 20 to 45 cm in total length when adult (Leonard and Ovaska 1998), that ranges from southern California to southern British Columbia (Cook 1960). Although the southern part of its range, to northern Oregon, is more-or-less continuous, the distribution of this species is highly fragmented in Washington and British Columbia (Leonard and Ovaska 1998). In British Columbia, Sharp-tailed Snakes are known only from a small number of scattered locations on southern Vancouver Island and some of the adjacent Gulf Islands. A previous report from Chase in the interior of British Columbia is of doubtful origin (Matsuda et al. 2006). Because of the low numbers of snakes found in Canada and few known sites, the snake was considered an endangered species by COSEWIC in 1999 (COSEWIC 2002*). Although formal study of Sharp-tailed Snakes has been limited, recent studies done in British Columbia and adjacent Washington cover aspects of their ecology such as defensive behaviour (Ovaska and Engelstoft 1999; Leonard and Stebbins 1999), aggregative behaviour (Leonard et al. 1996),

movements (Engelstoft et al. 1999), habitat (Leonard and Leonard 1998), and cover use (Engelstoft and Ovaska 2000).

Most of the areas where the Sharp-tailed Snake is found in British Columbia have fairly dense human populations and highly disturbed habitat. Consequently, many of the sites at which snakes are found are on private land. Although the Sharp-tailed Snake seems somewhat tolerant of anthropogenic habitat disturbance, habitat loss is still considered the primary threat to its persistence in Canada. Therefore, management and stewardship by landowners are important factors in conservation programs for this species.

The aim of this study was to determine the key characteristics that define habitats used by the Sharp-tailed Snake, in order to guide future habitat management. We did this by comparing sites known to be used by Sharp-tailed Snakes with sites that were subjectively similar but not known to be used (potential sites), and with locations chosen at random with respect to both known and potential site types. The first comparison objectively tested whether potential sites actually are similar to those sites known to be used by these snakes and the second tested whether Sharp-tailed Snakes use a subset of those habitats that are available. Initial observations suggested that south-facing rocky slopes and forest clearings appeared to provide the most suitable habitat for this species (see also Leonard and Leonard 1998), but no quantitative assessment of habitat characteristics has previously been done. Thus, we measured a wide range of possibly influential habitat variables at each sample location and compared them statistically among locations.

Although our comparisons among sites and locations were objective, selection of potential sites obviously was biased by our general knowledge of snake ecology and our previous experience with Sharp-tailed Snakes. This mainly reflected an aim of the recovery program for this species to find as many occupied sites as possible.

Study Area

In the past few years, federal lands in the Capital Regional District (including Gulf Islands National Park, Department of National Defence lands, and Coast Guard properties) have been assessed and rated for suitability as habitat for the Sharp-tailed Snake (Engelstoft and Ovaska 1998*). These sites are in various locations on North and South Pender Islands, Saltspring Island and southern Vancouver Island. In addition, artificial cover objects (ACOs) have been installed at all sites at which Sharp-tailed Snakes are known to occur, including private lands, and at sites rated as having high potential as habitat for these snakes. ACOs provide easily sampled, attractive cover and, combined with naturally occurring cover objects, are an effective means of determining presence of snakes (Engelstoft and Ovaska 2000). Sharp-tailed Snakes are secretive and rarely seen in the open, and ACOs provide the main means by which they are discovered in the field. Potential sites in this study were identified by CE based on his extensive field experience with Sharp-tailed Snakes.

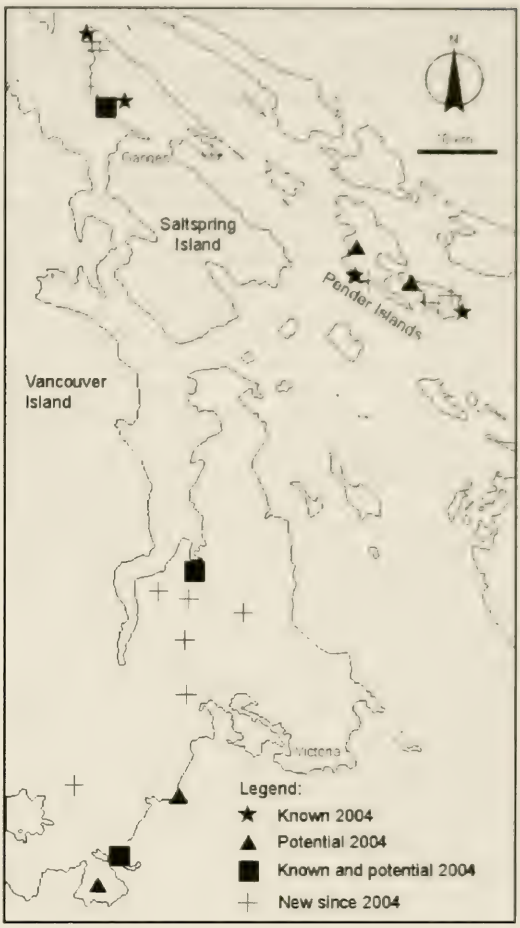

FIGURE 1. Map of study area with sites known to be occupied by Sharp-tailed Snakes up to 2004 and since, and potential sites identified in 2004. Squares labeled "known and potential 2004" indicate known and potential sites that are too close together to represent separately on this map. For reference, latitude and longitude for Victoria are 48°25'N and 123°19'W, respectively, and for Ganges 48°51'N and 123°31'W, respectively. Modified from a map obtained from the Natural Areas Atlas on the Capital Regional District (2008*) website.

The sites where ACOs have been placed can be classified into two general types. Unrestricted sites are those with relatively large extents of contiguous habitat under the same ownership surrounding the location of the ACO. These areas typically have experienced relatively little disturbance in the last century (e.g., Department of National Defence lands or Canada Parks lands). Restricted sites are those on relatively

small, privately owned properties surrounded by private lands in relatively developed areas. These locations have generally experienced a greater degree of habitat modification (buildings, roads, gardens, etc.).

Methods

Fieldwork for this study was undertaken in summer and autumn of 2004. Our general sampling scheme was straightforward. The 31 sites were divided into two site types, those known to harbour Sharp-tailed Snakes (known knowns) and those that appeared to have the potential to harbour them (known unknowns). Hereafter, we call these known and potential sites, respectively (Figure 1). At each of these sites, in addition to the known or potential *assigned* location, we also chose a corresponding *random* location (unknown unknowns) for sampling. Random locations were 50 m from an assigned location, but in a randomly chosen direction. Because 50 m was well within the known movement capabilities of *Contia* (Engelstoft et al. 1999), yet far enough away for the environment to vary significantly, this distance provided a test of non-random use of the local habitat. However, because most known sites are restricted, we were able to obtain a random location for only seven of the 16 known sites (compared to 14/15 for potential sites). Our sampling protocol was thus dictated to a large degree by access to private property, and by the amount of contiguous habitat under the same ownership surrounding the site. The total number of assigned and random locations at all sites combined was 52. At each of these locations, we took samples along three randomly chosen 10-m-long transects.

The first transect at each assigned location was placed in a random direction from a randomly chosen ACO, so that the 0-m mark was at the centre of the ACO. The other two transects were placed at two different randomly chosen locations (and in random directions) within a 25-m radius of the initial ACO. We measured canopy cover, aspect, and slope of location at the 0-m mark of the first transect; that is, these variables were measured once per location. All other variables were measured along each of the three transects (i.e., three replicates for each location). This same protocol was repeated for random locations, with a point on the ground standing in for an ACO. We ensured that transects around an assigned location and its associated random location did not overlap or abut each other.

We measured the following variables at each of the 52 locations:

1. **Percentage canopy cover** — Canopy cover was measured once for each location at the starting point of the first transect, directly overhead, and then at a 45° angle in each of the cardinal directions (south, north, east and west – surrounding canopy cover). The tree species making up the canopy cover also were recorded.
2. **Aspect** — The aspect of each location was measured in degrees using a compass at the starting point of the first transect. A measurement of 180° indicates a southerly aspect.
3. **Slope** — The general slope of the location was recorded in degrees as well as the slope for each separate transect. Both were measured using a compass equipped with a clinometer.
4. **Substrate** — At the 1-m mark along each transect, we determined the depth of both soil and litter layer by measuring the distance a thick wire penetrated into the ground. The composition of the litter (needles, leaves, etc.) also was recorded.
5. **Rock coverage** — Rock coverage was determined at each transect by measuring the total distance intercepted by rocks along the length of the transect. The rocks were rated by size as follows: loose gravel (pebbles <7.5 cm), cobbles (7.5-19.9 cm), rocks (20-50 cm), boulders (>50 cm), and bedrock.
6. **Coarse woody debris** — This was determined by measuring the total distance intercepted by coarse woody debris along the transect. Each piece of coarse woody debris was identified to species (if possible), and assigned a decay class (1-5) as per Table 5.13 in Meidinger (1998*).
7. **Vegetation** — Shrub cover and ground cover were determined by measuring the total distance intercepted by vegetation along the transect. For logistical reasons, coverage by each of lichens, bryophytes, grass and forbs was expressed as the total distance intercepted by these plants between the 2-m and 4-m marks of each transect.

Statistical Analyses

We used SAS 8.0 to analyze the data, except for aspect, which we also analyzed using ORIANA software. We compared locations and site types using both univariate and multivariate statistics. Although one level of the factor "location" was a randomly selected partner to a known or potential assigned location for Sharp-tailed Snakes, all factors (site, site type, location) were treated as fixed factors because all sites initially were chosen deliberately as particular site types and locations. In cases of non-orthogonal data, we used Type III sums of squares for F-tests. As this was essentially an exploratory study, we used a liberal criterion for tests of significance, highlighting all results for which $P < 0.10$.

Most variables showed no clear pattern of heterogeneity among categories of sites, so we combined them in various ways, which also reduced the number of variables to manageable levels, as follows: total shrub coverage (all shrubs – e.g., broom, Oregon grape, salal); tall, non-shrub coverage (ferns and asters); thick ground cover (e.g., ivy, periwinkle, trailing blackberry); light ground cover (lichens, bryophytes, grasses, forbs); rock cover (sum of all rock-size classes); coarse woody debris (sum of all CWD decay classes); and surrounding canopy cover (average of directional values around sample location). All other variables (e.g. overhead canopy cover, soil depth, slope) were left unaltered.

Because assigned and random locations were paired at unrestricted sites, we compared them via a 2-way factorial analysis of variance (ANOVA), with the three transects treated as replicates within each combination

of site and location. We did this analysis separately for known and potential site types, as they were in different places. In each case, we had to drop restricted sites from the analysis because they lacked a random location. In all cases in which the interaction between factors was non-significant, we dropped it from the analysis to test main factors only. In cases in which the interaction was significant, compromising interpretation of main effects, we then did a comparison of locations for each site separately.

To compare known and potential site types, we used a nested ANOVA (sites nested within site type), analyzing assigned and random locations separately, with transects serving as replicates within locations. F-tests were adjusted to those appropriate for nested ANOVA (Sokal and Rohlf 1981).

Because aspect is an angular variable, with the lowest possible value (0°) identical to the highest possible (360°), we treated it differently from the other variables. We categorized aspect at each location as one of four quadrants representing the four cardinal directions and then compared frequency of directions among site type/location categories (known/assigned, known/random, potential/assigned, potential/random) by contingency-table analysis. We also used circular (angular) statistics, as described by Zar (1984), to compare mean aspect between pairs of site type/location categories.

In addition to aspect, a few other variables (e.g. canopy cover) were recorded only once for each location, rather than separately for each transect. We therefore reduced the data set to average values for each location and then analyzed those new variables using two-way ANOVA (site × type × location, sites serving as replicates within each combination of factor levels). Again, we dropped the interaction term when it was non-significant, but did a separate comparison of locations at each site type when the interaction was significant. We also tested for correlations among these variables across all sites/locations.

Studies of habitat relationships are necessarily multivariate (Reinert 1993) and typically involve methods such as Principal Components Analysis (PCA) and Discriminant Function Analysis (DFA). In comparing categories of habitats, such as we have in this study, two approaches are possible (Quinn and Keough 2002). One is the multivariate analysis of variance (MANOVA) approach embodied by Discriminant Function Analysis (DFA). A second is to do a Principal Components Analysis (PCA) of all groups combined and then compare the derived components among groups using univariate ANOVA. Although the two approaches do not produce identical results, they generally result in broadly similar patterns of group differences (Quinn and Keough 2002). Advantages of the PCA approach include ease of analysis of multiple derived components and straightforward *post hoc* comparisons of particular groups (Quinn and Keough 2002), so we used it here.

To avoid pseudo-replication, especially for variables for which only one measurement was made per location (see above), we used the reduced data set (i.e., means of the three transects treated as data) for multivariate analysis. Using the same variables as in the ANOVAs above, we subjected the data to PCA, examined each of the first three principal components for influence of the original variables, and then treated each of the principal components as variables in separate two-way ANOVAs (as above). We also used the first principal component (PC 1) as the independent variable in a logistic regression comparing sites/locations known to be used by *Contia* vs. all other sites.

Results

Two-way ANOVAs using individual transect data as values yielded few differences attributable to location, although sites differed significantly for several variables. In comparisons of assigned vs. random locations for known site types, we found an effect only of rock cover, which was higher at assigned than at random locations ($F_{1,34} = 3.42$, $P = 0.07$). In cases of variables for which there was a significant interaction between site and location (extent of litter, slope of transect, coarse woody debris), differences between locations were significant at some sites, but not in any consistent direction.

For potential site types, assigned and random locations differed only in thick ground cover ($F_{1,69} = 38.8$, $P = 0.053$), which was higher in assigned locations. Sites again differed significantly for several variables and the interaction between site and location was significant for four variables (extent of litter, rock cover, light ground cover, shrub cover). Patterns from interactions again generally were indistinct, but for the three sites that differed significantly in rock cover, the value was higher at assigned than random locations; for three sites differing significantly in shrub cover, the value was lower at assigned locations.

Nested ANOVAs comparing assigned locations between known and potential site types showed only that known site types had lower soil depth ($F_{1,29} = 3.20$, $P = 0.08$) and less coarse woody debris ($F_{1,29} = 7.45$, $P = 0.01$) than potential site types. Again, there were significant differences among sites for some variables. Similar comparison of random locations between known and potential site types revealed only that rock cover was higher at known site types ($F_{1,19} = 3.15$, $P = 0.09$), with sites again varying significantly for some variables.

Two-way ANOVAs, using mean values (per 3 transects) as data (and all site type × location combinations, $n = 52$), revealed more differences (Table 1). Overall (i.e., assigned and random locations considered together), known site types had shallower soil ($F_{1,49} = 2.92$, $P = 0.09$), shallower litter ($F_{1,49} = 2.95$, $P = 0.09$), and higher rock cover ($F_{1,49} = 4.67$, $P = 0.04$) than

TABLE 1. Statistical summary of main habitat variables by site type (known vs. potential) and location (assigned vs. random). Only variables that were significantly different in at least one analysis (see text) are shown. Individual data are means for 3 transects at each site type/location combination; shown in the table are mean (top row) and ± standard deviation, minimum value – maximum value (bottom row) of these transect means.

Site type	Known		Potential	
Location	Assigned (n = 16)	Random (n = 7)	Assigned (n = 15)	Random (n = 14)
Rock Cover (m)	2.7	2.1	1.6	0.9
	2.45, 0 – 7.46	2.24, 0.02 – 6.03	1.78, 0.02 – 6.40	1.04, 0.01 – 3.11
Coarse Woody Debris (m)	0.1	0.6	0.4	0.5
	0.18, 0 – 0.71	1.37, 0 – 3.70	0.43, 0 – 1.71	0.72, 0 – 2.07
Thick Ground Cover (m)	0.6	0	0.3	0.03
	0.96, 0 – 3.50	0, 0 – 0	0.56, 0 – 1.61	0.05, 0 – 0.14
Shrub Cover (m)	1.8	2.3	1.8	3.5
	1.83. 0 – 5.29	1.42, 0.41 – 4.00	1.85, 0 – 6.95	3.04, 0 – 9.95
Soil Depth (cm)	6.6	8.4	9.0	9.4
	2.44, 3.5 – 10.9	3.58, 3.6 – 13.2	4.85, 4.3 – 22.2	4.30, 2.7 – 17.0
Litter Depth (cm)	2.1	2.2	2.7	3.3
	1.26, 0 – 4.3	1.46, 1.0 – 5.3	1.14, 0.7 – 4.2	2.23, 0.7 – 8.7
Overhead Canopy (%)	28.8	17.1	7.3	28.2
	21.17, 0 – 60.0	22.15, 0 – 50.0	14.25, 0 – 50.0	21.6, 0 – 50.0
Surrounding Canopy (%)	25.4	21.1	19.1	35.1
	12.39, 2.5 – 52.5	16.51, 0 – 42.5	14.74, 0 – 46.3	18.66, 0 – 52.5
Transect Slope (°)	13.0	15.4	11.2	7.7
	7.76, 0 – 28.33	15.39, 0 – 45.33	9.56, 0 – 27.67	7.24, 0.67 – 27.33

potential site types, on average. Assigned locations had more thick ground cover ($F_{1,49} = 4.15$, $P = 0.047$), less shrub cover ($F_{1,49} = 3.59$, $P = 0.06$), less overhead canopy cover (potential site types only, $F_{1,27} = 9.55$, $P = 0.005$) , less surrounding canopy cover (potential site types only, $F_{1,27} = 6.62$, $P = 0.02$), and steeper transect slopes (potential site types only, $F_{1,27} = 5.90$, $P = 0.02$) than random locations, on average.

As expected, many of the variables above were significantly correlated over all site types/locations (n = 52 in all cases). These included mean soil depth vs. mean litter depth (r = 0.40, $P = 0.004$), mean rock cover vs. mean litter depth (r = -0.29, $P = 0.04$), mean soil depth vs. mean rock cover (r = -0.38, $P = 0.005$) and overhead canopy cover vs. surrounding canopy cover (r = 0.58, $P < 0.0001$).

Direction (aspect) differed significantly among site type/location categories (Fisher's exact test, $P = 0.004$). Thirteen known/assigned locations (81%) faced south and the rest (3) all faced west, whereas only six (40%) of potential/assigned locations faced south and another six faced east. Potential/random locations were particularly deviant from known/assigned, with eight (57%) facing either north or east. These results were consistent with those from analysis via circular statistics (mean vectors: known assigned – 203.99°; known random – 215.15°; potential assigned – 155.73°; potential random – 125.86°). Significant differences between site type/location categories were as follows: known assigned vs. potential assigned – $F_{1,29} = 4.27$, $P = 0.05$; known assigned vs. potential random – $F_{1,28} = 7.21$, $P = 0.01$; known random vs. potential assigned – $F_{1,20} = 3.02$, $P = 0.1$; known random vs. potential random – $F_{1,19} = 3.55$, $P = 0.07$, although this last result may not be reliable because of a uniform distribution of points.

We ran PCA using various combinations of variables, dropping those that had low weights on PC 1. Results were broadly similar in all cases, but they were most clearly defined when we used mean rock cover, mean soil depth, mean surrounding canopy cover, and mean shrub cover as variables in the analysis. In that case, PC 1 accounted for 44% of the total variance and PC 2 and PC 3 23% and 20%, respectively. This high cumulative percentage variance for the first three principal components suggests that they summarized the data efficiently (McGarigal et al. 2000). PC 1 was positively weighted by soil depth, surrounding canopy cover, and shrub cover, but negatively weighted by rock cover (Table 2).

Two-way ANOVAs on the PCs showed that PC 1 differed overall between both site types ($F_{1,49} = 4.19$, $P = 0.046$) and locations ($F_{1,49} = 4.84$, $P = 0.03$). Known site types had lower average values of PC 1 than potential site types and assigned locations had lower values than random, consistent with the two-way ANOVAs performed above on the individual variables and with the signs of coefficients in PC 1. Random locations had higher values of PC 2 than assigned locations, but only for potential site types ($F_{1,27} = 3.86$, $P = 0.06$). Neither site types nor locations differed with respect to PC 3.

Despite statistically interesting differences in PC 1 between site types and locations, differences overall

TABLE 2. Summary of weights (coefficients) of four variables on first three principal components in analysis of habitat variables potentially influencing occurrence of Sharp-tailed Snakes. PC 1 accounts for 44% of variance and PC 2 and PC 3 23% and 20%, respectively.

Variable	PC 1 Coefficients	PC 2 Coefficients	PC 3 Coefficients
Soil Depth	0.497	-0.591	0.346
Surrounding Canopy Cover	0.440	0.549	0.670
Shrub Cover	0.489	0.490	-0.562
Rock Cover	-0.566	0.331	0.339

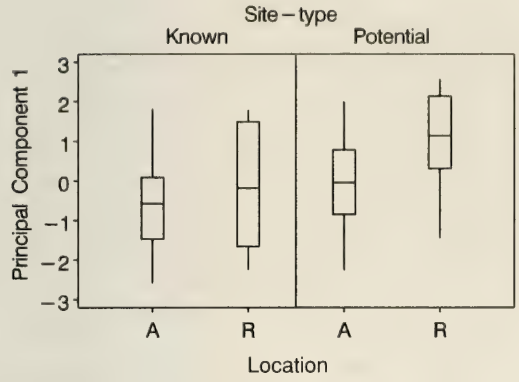

FIGURE 2. Box-and-whisker plots of values of principal component 1 by site type (known vs. potential) and location (actual, A, vs. random, R). Horizontal line in each box is median. Upper and lower boundaries of box (hinges) indicate quartiles (25th and 75th percentiles). Whiskers from box reach to the most extreme value that does not exceed 1.5 times the distance between the quartiles; $n = 52$.

among the four site type/location combinations were not large (Figure 2). In fact, differences among these categories were graded rather than discrete. We therefore divided site type/location combinations into two categories, those known to be occupied by Sharp-tailed Snakes and those not. The resulting binomial variable was then regressed (logistic regression) against PC 1. The logistic model was a satisfactory fit to the data (Homer and Lemeshow test, $\chi^2_8 = 4.46$, $P = 0.81$) and the relationship was significantly negative (Wald's $\chi^2_1 = 4.25$, $P = 0.04$; Figure 3). We also compared PC 1 of known/assigned locations successively, via logistic regression, to known/random, potential/ assigned and potential/random locations. The trend also was negative in each case, but significant (and strongly so) only in the last one. Thus, sites known to be occupied by Sharp-tailed Snakes differed from those not known to be occupied.

Discussion

The study of how and why animals occur in particular habitats has a long history in ecology and has been the subject of numerous reviews and syntheses (e.g.

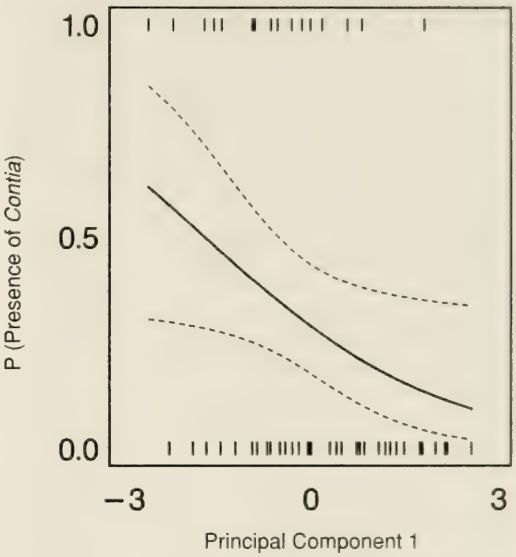

FIGURE 3. Logistic regression of presence(1)/absence(0) of Sharp-tailed Snakes vs. principal component 1 for all site type/location combinations. Absence implies "not recorded" rather than confirmed absence. Vertical lines are data points, solid line is predicted regression, and dashed lines are upper and lower 95% confidence limits on regression; n = 52.

Morse 1980; Gray and Craig 1991; Reinert 1993; Garshelis 2000). Habitat use by a species is a function not only of habitat selection based on resource requirements and physical factors such as temperature, but of other factors such as population density and the presence of competitors and predators (Huston 2002; Morris 2003). Thus, the habitats used by animals may not be those that are optimal for them in terms of fitness. In fact, it is even possible that some occupied habitats have negative implications for fitness (Van Horne 1983), for example if those habitats are sinks in a source-sink system (Pulliam 1988). Conversely, optimal habitats that could be used might not be occupied simply because the species' ability to disperse there is limited (Huston 2002). In short, the analysis and interpretation of habitat-use studies is fraught with difficulties (Garshelis 2000). In that light, this study

is but a small first step towards understanding the habitat relationships of the Sharp-tailed Snake. It is further limited by its reliance on presence/absence (really presence/not recorded) data rather than data on abundance, or better, demographic performance (Pulliam 1988; Garshelis 2000). In terms of Garshelis' (2000) classification of methods, our approach is a variant of the site-attribute design, but with the added inclusion of predetermined potential sites for the species' occurrence.

Animals typically do not use their environments at random, but non-randomly, selecting some sites over others because of particular habitat and micro-habitat features. Thus, the mere demonstration that places used by a particular species are different from those not used is unremarkable by itself. For the conservationist or manager, however, determining which habitat characteristics are important is fundamental to preservation, restoration, or even creation of habitats.

What are the key features that describe suitable habitats for the Sharp-tailed Snake? The data collected in this study were highly variable and can only hint at differences between site types and locations that appear to be important. More detailed, longer-term work with larger samples would allow us to reach stronger conclusions, but this study was limited by the small number of sites at which the Sharp-tailed Snake is known to occur in southwestern British Columbia. It also was limited by the subjectivity with which potential sites were identified. For example, south-facing slopes are often favoured by snakes and this is reflected in the distribution of known and potential sites in this study. However, a Sharp-tailed Snake recently was found on a north-facing slope on Pender Island (D. Spalding, personal communication), suggesting that the species may occur in a wider range of conditions than previously thought. Currently, a more randomized approach to sampling sites for Sharp-tailed Snakes is under way to reduce this kind of bias, but we still have some way to go before we can convincingly move known and unknown unknowns to the fully known side of the ledger.

Aside from the necessary constraints of small numbers of known sites for Sharp-tailed Snakes, this study also might have been limited by failure to measure key environmental variables. For example, as is the case for other ectotherms, the ecology of Sharp-tailed Snakes is no doubt strongly influenced by temperature, which will affect the kinds of habitats and microhabitats they use at different times (Huey 1991; Reinert 1993; Blouin-Demers and Weatherhead 2001). Similarly, given the potential for desiccation in this small species, as well as a requirement for incubation sites for eggs, moisture also is likely to be an important physical factor. Therefore, cracks and openings for underground access and suitable sites for egg-laying or hibernation are potentially critical habitat features for these snakes. However, measuring subterranean access would be very difficult and we know nothing about the kinds of sites favoured by Sharp-tailed Snakes for egg deposition or for spending the winter. To deal adequately with temperature and moisture, we would need to measure them across all seasons and in multiple microhabitats per location simultaneously.

Despite these deficiencies, we found fairly clear indications that sites used by Sharp-tailed Snakes tend to be south-facing and to have relatively shallow soil and litter, relatively high rock cover, and relatively low shrub cover. Differences from randomly chosen sites emphasize this species' non-random use of habitats, but differences between locations actually used by snakes and those deemed to be potential habitat underline the subjectivity of visual habitat assessment. That said, this subjective approach based on field experience has proven effective. Although none of the potential sites used in this study have since yielded evidence of Sharp-tailed Snakes, two of the known sites were initially identified by CE as potential sites and another site designated as potential by CE after this study was completed has since turned out to be occupied by Sharp-tailed Snakes. Even so, quantitative measures for objective assessment of potential sites also would be valuable. Future work could focus on variables found to be important in this study and on others that we were unable to measure, such as those mentioned above as well as shrub height, tree density, soil composition, drainage, and type of bedrock.

Given the rarity of the Sharp-tailed Snake in British Columbia and the obvious difficulties in studying rare species in general, perhaps an alternative (or supplementary) approach would be to undertake comparative studies of this species in more southerly parts of its range where it is more widespread and more abundant. Extrapolating from a species' ecology in one part of its range to another distant one requires caution as there may be significant adaptive differences in different areas. For example, Sharp-tailed Snakes in California occupy a wide diversity of habitats (D. Wake, personal communication), most of which do not occur in British Columbia. Nonetheless, this approach might reveal fundamental species' characteristics that can be used to delineate more clearly the critical habitats required for conservation of the Sharp-tailed Snake in British Columbia.

Acknowledgments

We thank Laura Matthias and Michelle Masselink for showing us sites known to be occupied by Sharp-tailed Snakes and Andrea Pilski for assisting in the field. The Sharp-tailed Recovery Team offered useful help and advice and both David Wake and David Spalding provided us with important personal observations. We also thank various landowners for allowing access to their land: Pender Island – Don and Theresa Williams, Sylvia O'Reilly, Robert Dill, Jon Crawford, Pat and Ian Haugh; Saltspring Island – Frances Hill and Dave Kerman, Sandra and Vince

Knight, Leslie Northey, Mark and Brenda Haughley. The British Columbia government provided staff time. The views presented are those of the authors, not their respective agencies. The Endangered Species Recovery Fund (World Wildlife Fund, Canada) and the Habitat Conservation Trust Fund (BC) provided financial support.

Harriman, Vanessa B., Justin A. Pitt, and Serge Larivière. 2007. Do repugnant scents increase survival of ground nests? A test with artificial and natural duck nests. Canadian Field-Naturalist 121(2): 150-154.

Ground-nesting birds typically experience high predation rates on their nests, often by mammalian predators. As such, researchers and wildlife managers have employed numerous techniques to mitigate nest predation. We investigated the use of scents as repellents to deter predators from both artificial and natural ground nests. Survival rates of artificial nests did not differ among six groups of substances (Wald $\chi^2_{df=5} = 4.53$, $P < 0.48$); however the chronology of predation among groups differed. A commercial Coyote urine based deterrent (DEER-D-TER™), human hair, and Worcestershire sauce were depredated faster than the control ($F_{4,5} = 40.3$, $P < 0.001$). Nest survival of natural nests differed among those groups tested (Wald $\chi^2_{df=2} = 11.8$, $P < 0.005$); the eight mothball treatment decreased survival (Wald $\chi^2_{df=1} = 11.5$, $P < 0.005$), which indicated that novel smells may attract predators or result in duck nest abandonment when coupled with natural duck scent. Chronologies of predation events among treatment groups were not different for natural nests ($F_{2,3} = 1.9$, $P = 0.22$). These findings indicate an interaction between novel scents and predator olfactory cues.

Key Words: Coyote, *Canis latrans*, urine, human hair, mothballs, napthaldehyde, nest predation, olfactory cues, waterfowl, Manitoba.

In the prairies of North America, predation on nests of ground-nesting ducks is considered the most important factor limiting waterfowl populations (Chafloun et al. 2002). As such, wildlife managers have developed and employed various techniques in an attempt to mitigate nest predation with varying degrees of success. Typically, a predation event by a mammalian predator such as the Striped Skunk (*Mephitis mephitis*), Red Fox (*Vulpes vulpes*), or Raccoon (*Procyon lotor*) is opportunistic (Larivière and Messier 1997). These predators are nocturnal and locate nests using audition (when the hen flushes) and olfaction (Larivière and Messier 1997). Although substances that may attract predators to nests have been investigated (Whelan et al. 1994; Clark and Wobeser 1997), scents that may repel predators from nests have yet to be tested.

Chemical compounds have been used successfully to repel animals, including mammals. Some animals have been effectively repelled by means of conditioned taste aversion (e.g., Hoover and Conover 1998) and through the use of noxious scents such as toxic compounds or odor from predatory animals (Sullivan et al. 1985; Rosell 2001).

We investigated the effectiveness of various scents to increase survival of duck nests in the Canadian prairies. Specifically, we tested whether applying DEER-D-TER™ (a commercial product containing Coyote (*Canis latrans*) urine), human hair, Worcestershire sauce, and mothball treatments could increase survival of eggs in artificial nests and the capability of DEER-D-TER and mothball treatments to increase the survival of eggs in natural duck nests. We also tested for differences in speed of predation events to determine whether specific scents may temporarily deter predators from a nest. Finally, we compared survival of eggs in artificial and natural nests.

Study Area

This study was conducted southeast of Minnedosa, Manitoba (50°14'54"N, 99°50'30"W), in an area supporting numerous small (<3 ha) seasonal to permanent wetlands (ca. 14% of study site) and characterized by intensive cultivation (63%) of small grains (wheat, barley, and oats) and oil crops (canola and flax). Intermixed among agricultural fields are small aspen bluffs composed of poplar species (largely Quaking Aspen (*Populus tremuloides*) and Bur Oak (*Quercus macrocarpa*). The predator community is diverse and includes Raccoons, Striped Skunks, Coyotes (*Canis latrans*), Red Foxes, American Badgers (*Taxidea taxus*), and American Mink (*Neovison vison*). Predation of bird nests in the area is largely attributed to mammals (Pasitschniak-Arts and Messier 1995) but avian predation also occurs, primarily by birds such as the Common Raven (*Corvus corax*), American Crow (*Corvus brachyrhynchos*), and Black-billed Magpie (*Pica pica*).

Methods

The effectiveness of five groups of substances was compared to a control using artificial nests. The repellent substances were chosen based on unsubstantiated reports of their efficacy against mammals (human hair

and Worcestershire sauce) or from their commercial claims (DEER-D-TER™ and mothballs). Nests in the control group were each treated with 0.1 L of marsh water, which was poured along the outside edge of the nest. A packet of DEER-D-TER™ was placed on the outside edge of each nest of the second group. DEER-D-TER™ consisted of a green plastic packet containing a mixture of sand and Coyote urine and was advertised to repel deer (*Odocoileus* spp.) and skunks. According to the manufacturer, this product was effective in the field for ca. 90 days. Group three received one cup of human hair which was collected from three different salons and was combined to create a homogeneous mixture. Group four received 0.15 L of Worcestershire sauce applied evenly to each egg and was reapplied on every subsequent visit. The fifth group received four mothballs double wrapped in cheesecloth to prevent accidental ingestion by ducks or predators. The sixth group received eight mothballs, to determine if a greater amount yielded a different or stronger response, with two cheesecloth-wrapped groups of four mothballs placed on opposite sides of the outside edge of the nest. Three groups of substances were applied to natural nests: marsh water, DEER-D-TER™, and eight mothballs. Methodology and application of treatments for natural nests followed the same protocol as those of artificial nests.

Data were collected from 12 June to 7 July 2002. Artificial nests were created by depositing six medium-sized chicken eggs in a depression which was then covered with grass. Nests were marked by a thin welding rod at a distance of 1 m. To avoid biases associated with

habitat, all artificial nests were deployed in rights-of-way. Each nest was randomly placed within a 0.8 km stretch along four different, but intersecting, secondary unpaved grid roads. Artificial nests were located 300-1000 m apart on alternating sides of the road. Nests were placed in the densest vegetation as close as possible to the randomly selected location to reduce possible effects of concealment on survival. Artificial nests were visited every five days for 25 days and were approached from a different angle each visit to avoid the creation of a pathway to the nest. Rubber boots and latex gloves were worn at all times in hopes of concealing human scent. Each nest was randomly assigned one test substance until an equal number of nests per treatment was obtained.

Natural nests were located via the drag chain method. Only upland areas of dense nesting cover were searched and nests were marked with stakes placed 10 m away in a random direction. Nests were located on four separate quarter sections within 1.6-8.0 kilometers of each other. Each quarter section consisted of dense nesting cover and was bordered by either a crop or fallow land and a secondary gravel road.

Treatments of natural nests were assigned systematically because we were unaware of how many nests we would eventually locate and we sought to have a similar number of nests per treatment. If, on return to nests treated with mothballs, any of the mothballs had fallen out of the cheesecloth, the entire packet was replaced with a new one. Hens often incorporated the wrapped mothballs into their clutch and occasionally moved the packet(s) directly (< 0.5 m) outside of the nest bowl. In these cases, the wrapped mothballs were left where the hen placed them. The first re-visit to the nest occurred between five and eight days after initial location and treatment application. Subsequent visits were made every seven days for up to a total of five visits depending on the fate of the nest. Natural nests were excluded from the analyses if they were abandoned but not depredated. However, we were unable to determine whether a nest had been abandoned and subsequently depredated.

All nests were deemed depredated (failed) after at least one of the eggs was removed from or destroyed in the nest. Mayfield logistic regression (Hazler 2004) was used to determine whether the nest survival of each treatment group differed from the nest survival of control nests within each nest type (artificial or natural). Because nests were not visited daily the exact date of failure was unknown. The number of days a nest was active ("exposure days") was calculated differently depending on the fate of the nest. Exposure days of nests that hatched (or survived to the last day of the study in the case of artificial nests) was the number of days that nest was under observation. Exposure days of failed nests was the number of days the nest was known to be active plus the midpoint between the last check and the last known active day. Nests that fail early are less likely to be detected and the Mayfield logistic regression reduces this bias by incorporating exposure days. Also, because this is a logistic-regression analysis, covariates can be incorporated, allowing for easy analysis of experimental data (Hazler 2004). All artificial nests were deployed on the same day and nest dragging was completed within three days which minimized the potential impact of seasonality on the data. An analysis of variance with repeated measures was used with respect to nest survival as a function of exposure days to determine whether there was a difference in the chronology of predation events between treatments as time progressed. All post-hoc tests were conducted using an all-pair-wise comparison Tukey test. Survival of artificial and natural nests was compared using Mayfield logistic regression.

Results

Survival of eggs in artificial nests was higher than that of natural nests (Wald $\chi^2_{df=1} = 43.4$, $P < 0.001$). Artificial nest daily survival was 0.54 (SE ± 0.003) for all substances combined, while daily nest survival for natural nests was 0.04 (SE ± 0.01) for all substances combined.

We deployed 120 artificial nests, with each treatment group containing 20 nests. Due to flooding, seven artificial nests were lost at various phases of the experiment and were excluded from further analyses. We found no significant difference in artificial nest survival rates among treatment groups (Wald $\chi^2_{df=5} = 4.5$, $P = 0.48$; Figure 1).

For all treatments combined, there was a positive correlation between survival of artificial nests and exposure days, with survivorship of nests increasing with time ($F_{4,25} = 6.77$, $P < 0.001$) and the first five exposure days being the most fatal (Figure 2). Additionally, the chronology of predation differed among groups ($F_{4,5} = 40.3$, $P < 0.001$). Artificial nests containing both four and eight mothball treatments were depredated similarly to control nests ($q = 1.63$, $p = 6$, $P > 0.05$; $q = 1.40$, $p = 6$, $P > 0.05$). However, nests treated with DEER-D-TER™ ($q = 9.14$, $p = 6$, $P < 0.05$), human hair ($q = 4.84$, $p = 6$, $P < 0.05$), and Worcestershire sauce ($q = 13.9$, $p = 6$, $P < 0.05$) were depredated more quickly than control nests.

In total, 70 natural duck nests were located, with 24 receiving the control, 23 treated with DEER-D-TER™, and 23 treated with eight mothballs. Natural nest survival of the treatment groups differed from that of the control (Wald $\chi^2_{df=2} = 11.82$, $P < 0.005$; Figure 3) with survivorship of nests treated with eight mothballs being significantly lower (Wald $\chi^2_{df=1} = 11.47$, $P < 0.005$).

Nest survival did not vary as a function of exposure days for all natural duck nests combined ($F_{3,8} = 2.14$, $P = 0.17$) despite a notably rapid decrease in nest sur-

vival during the first five exposure days (Figure 4). Nest survival did not vary as a function of exposure days among treatments for natural duck nests ($F_{3,8} = 1.99$, $P = 0.22$).

Discussion

We assessed the effect of various scent treatments on the survivorship of artificial and natural duck nests in the prairie pothole region of Canada. The application of scents did not increase nest survival of artificial or natural nests. Addition of mothballs decreased survival of natural nests. These results not only indicate that DEER-D-TER™, human hair, Worcestershire sauce, and mothballs were ineffective at repelling predators, but that certain scents may actually attract predators and/or increase duck nest abandonment rates.

The chronology of predation differed among treatments for artificial nests but not for natural nests. Contrary to expectations, artificial nests treated with DEER-D-TER™, human hair, and Worcestershire sauce were depredated more quickly than control nests. Again these results may indicate a neophilic predator response. In particular, human-associated scents (i.e., hair and food items) may elicit predator attraction depending on the study site and the animal's experience with people. Although this study took place in a rural location, it is plausible that local predators may have positive associations with human dwellings and food, especially opportunistic species such as Striped Skunks and Raccoons (Pitt et al. 2008). Raccoons in particular often rely on anthropogenic foods at the northern edge of their range distribution (Larivière 2004; Pitt et al. 2008). Additionally, DEER-D-TER™ may have also attracted predators to nests, especially con-specifics. Mothballs and hair regularly went undisturbed at depredated nest sites whereas urine packets were often chewed on and/or ripped open.

The result of predators exhibiting neophilic tendencies may have important implications for waterfowl due to the propensity for which they are studied. The concealment of human scent should be an important consideration for researchers. Neophilic predators may increase their search radius when a particular scent cue is present (Whelan et al. 1994), possibly rendering human-visited nests more susceptible to predation.

Our study indicates that the survival rates of artificial and natural duck nests in the prairie pothole region are different and this may indicate that these nests are viewed differently from the perspective of a predator. Artificial nests realized higher survival rates compared to natural nests, which has been previously documented (Guyn and Clark 1997). The disproportionate difference in survival between artificial and natural nests could also in part be attributed to the presence of scents associated with natural nests, as well as the presence of a hen and the ability to cue in on the nest after a flush event (Larivière and Messier 1997). Alternatively, the observed difference may have been mediated by uncontrolled factors affecting natural nest survival, such as nest abandonment, hen species and behavior, nest concealment, and variation in nest spacing. Specifically, the eight mothball treatment may have provoked abandonment by nesting female ducks as some ejected mothballs from nests.

Conditioned taste aversion has been effective in deterring predators from nests (Nicolaus 1986; Conover 1990). Napthaldehyde (the noxious substance in mothballs) has been found to be effective in causing adverse responses by Coyotes when ingested (Hoover and Conover 1998). After repeated exposure, Coyotes avoided eggs injected with napthaldehyde. Although highly successful, it is expensive and time consuming to set up nests with injected chemicals. For future studies, it may be equally effective and less time consuming to combine the use of conditioned taste aversion with scents. Our results indicate that applied by themselves, these scents do not increase survival of either artificial or natural duck nests.

Acknowledgments

Delta Waterfowl Foundation provided funding and assistance for this study. Ducks Unlimited Canada kindly granted permission to search nesting cover. D. Coulton, H. Remenda, J. Estrella provided assistance in the field. Two reviews contributed to the clarity of the manuscript. This research was approved and conducted under Manitoba Wildlife Animal Care Committee #2002-10. SL was supported through a National Science and Engineering Research Council discovery grant.

Stronen, Astrid Vik, Paul Paquet, Stephen Herrero, Seán Sharpe, and Nigel Waters. 2007. Translocation and recovery efforts for the Telkwa Caribou, *Rangifer tarandus caribou*, herd in westcentral British Columbia, 1997–2005. Canadian Field-Naturalist 121(2): 155-163.

During 1997–1999, 32 Woodland Caribou (*Rangifer tarandus caribou*) were translocated from the Sustut Herd to the Telkwa Mountains in westcentral British Columbia to augment recovery of the Telkwa Caribou Herd. The animals were fitted with radiocollars and located during 1997–2000 to determine selection of habitat features and terrain variables. Six Caribou calves were also collared to determine causes and timing of calf mortality during summer 1999. Defining available habitat for newly translocated animals is often arbitrary and subjective, and we based the analyses on ranks for habitat use and availability as this is less sensitive to the inclusion or exclusion of a questionable resource. This method represents some loss of information but provides indications of the relative importance of various habitat types without classifying any as avoided. High elevation habitat (> 1700 masl) on moderate slopes (16 – 45°) received the highest ranks, as did "warm" (136 – 315°) aspects and forests > 250 years old. Three calves died shortly after birth. One calf appeared to have been killed by predation, likely by a Golden Eagle (*Aquila chrysaetos*), and one calf was abandoned by the cow. Cause of death for the third calf is unknown. To assess habitat use associated with calving we compared summer locations with data obtained throughout the rest of 1999 for eight cows with calves and eight without calves. We found significant difference in use of elevation during calving time, when cows with calves remained at high elevations and barren cows generally descended to lower elevation habitat. Surveys conducted in 2005, five years after the completion of the initial study, produced a count of approximately 90 Caribou. This suggests that in the short term, the translocation was successful in re-establishing a self-sustaining Caribou population in the Telkwa Mountains.

Key Words: Woodland Caribou, *Rangifer tarandus caribou*, calf mortality, calving habitat, habitat selection, rank analysis, wildlife management, British Columbia.

Woodland Caribou (*Rangifer tarandus caribou*), populations have generally experienced decline and range reduction over the last century in British Columbia (Heard and Vagt 1998), across Canada (COSEWIC 2000*) and throughout the circumpolar region (Mallory and Hillis 1996). Causes of decline include a combination of habitat loss, habitat fragmentation, increased human access, hunting and predation (Bloomfield 1980; Edmonds and Bloomfield 1984; Heard and Vagt 1998), poaching (Edmonds 1988), and possible interactions between disturbance and predation (Mallory and Hillis 1996). Woodland Caribou in the Southern Mountain National Ecological Area of British Columbia (including the Telkwa Caribou Herd) were designated as threatened in 2000 (COSEWIC 2000*). Caribou were once widely distributed throughout the mountainous areas surrounding Telkwa and Smithers, British Columbia, and might have formed part of a larger herd whose range extended south into Tweedsmuir Provincial Park (TCHRP 1998*). Few data are available on the Telkwa Caribou Herd before 1997; however, surveys indicated fluctuations in herd size from less than 100 in 1949 to a high of 271 in 1965. A hunting closure was implemented for the herd in 1973 but only 68 animals were counted in 1984 (van Drimmelen 1986*) and monitoring flights in the 1990s resulted in counts of less than 20 Caribou (TCHRP 1998*). During 1997–1999, 32 Caribou were captured from the Sustut Herd about 150 km north of Smithers and translocated to the Telkwa Mountains to help the recovery of the Telkwa Caribou Herd.

Translocation is now a common tool in the recovery of populations at risk (Griffith et al. 1989) and the need for documenting habitat use and availability is critical in efforts to preserve endangered species and manage small populations (Manly et al. 1993). We studied habitat use and calf survival of the Telkwa Caribou Herd from 1997 to 2000 to determine preliminary habitat selection of translocated animals and assess timing and causes of calf mortality. With small populations following a translocation, there are usually limited data available to investigate habitat selection, and therefore little or no information for land managers. Although defining available habitat for newly translocated animals is often arbitrary and subjective, a preliminary evaluation of habitat selection can provide some infor-

mation on priority areas for protection when assessing other land uses such as forestry and recreation. Translocation success can be evaluated in three phases: (1) initial occupation and reproduction in the new ecosystem; (2) presence of a short-term self-sustaining population, and (3) ultimate population recovery (Compton et al. 1995). We outline findings on habitat selection and calf mortality between 1997 and 2000 and report for phases 1 and 2 of the Telkwa Caribou Herd Recovery Project. We also discuss challenges involved in providing habitat management priorities based on preliminary data from a small reintroduced population.

Study Area

The study area comprises approximately 25 000 km^2 in westcentral British Columbia, with elevations ranging from 300–3000 meters above sea level (Figure 1). It is situated between 53.40 and 55.20 degrees of latitude north and 125.10 to 128.30 degrees of longitude west. Glaciers, rugged peaks, high alpine plateaus, and deep glaciated U-shaped valleys with extensive wetlands characterize the alpine areas. Major tree species in the study area include Subalpine Fir *(Abies lasiocarpa)*, Engelmann Spruce *(Picea engelmannii)*, and Hybrid White Spruce *(Picea glauca × engelmannii)*. The climate has both coastal and inland influences, with cool summers and moderately cold winters. Precipitation averages 500 mm per year, of which about half falls as snow. The Telkwa Mountains have a population of approximately 250 Mountain Goats (*Oreamnus americanus*), and lower elevations have populations of Moose (*Alces alces*), Mule Deer (*Odocoileus hemionus hemionus*), and some Elk (*Cervus elaphus*). Large predators within the range of the Telkwa Caribou Herd include: Grizzly Bears (*Ursus arctos*), Black Bears (*Ursus americanus*), Wolverine (*Gulo gulo*), Wolves (*Canis lupus*), Coyotes (*Canis latrans*), and Golden Eagles (*Aquila chryseatos*). To account for the difficulty in defining available resources for the herd and thus delineating our study area, where most animals have had < 2 years of experience, we selected an area of available habitat based on three factors: (1) locations of collared caribou 1997-1998 (G. Schultze, British Columbia Ministry of Environment, personal communication); (2) Traditional Ecological Knowledge of the Telkwa Caribou Herd (B. Holland, Wet'suwet'en First Nation, personal communication in Stronen 2000) and (3) availability of forest cover data from the British Columbia Ministry of Forests (Inventory Branch, Victoria, scale 1: 20 000).

Methods

We located radiocollared animals throughout the year from fixed wing aircraft (Cessna 206, 185, or 172) using standard telemetry equipment. Tracking intervals varied from every four days to every three weeks, depending on funding, season, and weather conditions. We determined geographic location using yoke-mounted, handheld, or panel-mounted Global Positioning System (GPS) units and noted habitat characteristics, activity, group size, and presence of young. The accuracy of relocation data was tested and averaged ± 300 meters. Most locations were determined during morning or mid-day. For the purpose and scale of this study, the data were assumed representative of Caribou habitat use for day and night. Six calves were captured shortly after birth and equipped with radiocollars during the summer of 1999. Caribou calves were captured as close to within 24 hours of birth as possible using a Bell 206 Jet Ranger and a Long Ranger helicopter and a capture crew of three people. Calves were sexed, weighed, and fitted with VHF radiocollars (Lotek Engineering, Newmarket, Ontario) with motion sensitive mortality sensors. We estimated age by assessing the presence/condition of the umbilical cord, condition of hooves and pelage, posture, and general appearance (Haugen and Speake 1958; Miller et al. 1988), and calculated weight by subtracting 0.6 kg for each day of estimated age (Adams et al. 1995). Handling time was approximately five minutes from capture to release. Calves were monitored daily, weather permitting, from date of capture until the end of August. During September and October, we monitored calves weekly and after October they were monitored as a part of regular telemetry flights for the herd. We investigated mortality signals via helicopter the day of discovery.

Data for elevation (meters above mean sea level), slope (%), and aspect (in azimuth measured from north) were derived from a Digital Elevation Model using Arc/INFO v. 7 software. Tiles from the Digital Elevation Model were merged to form a seamless grid covering the study area. Floating point grids were generated for slope and aspect and we created a variable combining elevation and slope. Data on habitat type (leading tree species or non-productive timber area), crown closure (%), and tree age (using leading tree species) were derived from Forest Cover Inventory Polygons (British Columbia Ministry of Forests, Inventory Branch, Victoria, scale 1: 20 000). Values for terrain and habitat variables were summarized (km^2) for the entire study area to determine percent availability of the various classes of each variable. Habitat availability was analyzed by the British Columbia Ministry of Environment's regional GIS data analyst, who also produced cartographic output. We used data collected between November 1997 and April 2000 to analyse habitat use and determined terrain and forest cover values for all telemetry locations. To assess habitat selection, we followed sampling design 2 of Manly et al. (1993), where individual animals were identified and the use of resources was measured for each individual, but availability was measured at the population level.

To assess habitat use associated with calving, we used locations for eight cows with calves (n = 123 locations) and eight without calves (n = 128 locations)

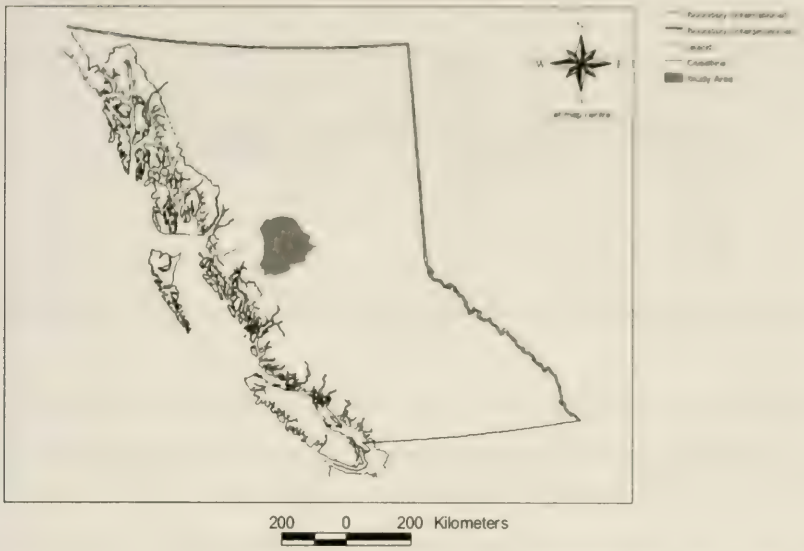

FIGURE 1. The study area in British Columbia, 1997 – 2000.

collected during the summer of 1999. We compared summer data (n = 150 locations) with locations obtained during the rest of the year (n = 145 locations) to account for differences not attributed to calving. Locations were divided into two groups:

(1) calving (25 May – 6 July)

(2) all-year (1 January – 24 May, and 7 July – 31 December)

We analyzed habitat selection using Resource Selection for Windows (RSW), a 32-bit Windows program for analyzing preference (Leban 1999). Using Johnson's (1980) method, which orders all variable components by rank for usage and availability, we measured habitat preference for each animal as the difference between the rank of usage and the rank of availability. We averaged these differences across animals to obtain a mean value for each habitat component and then compared the values to determine a ranking from least preferred habitat component to most preferred. We tested for habitat selection using alpha = 0.05. We compared habitat use of reproductive cows and cows without calves using analysis of variance (repeated measures, alpha = 0.05) within each group and within each season using SPSS 10.0 (SPSS Inc. 1999). The herd consisted primarily of translocated Caribou during the study and we considered the radio-collared animals to be a random sample of the Telkwa Herd.

Results

High elevation habitat on moderate slopes (> 1700 meters above sea level, 16 – 45%) received the highest ranks (Table 1). Caribou also made extensive use of the steep rugged mountains in the Telkwa range (>1700 m, > 45%). Aspects 136 – 315° received the highest rank (Table 2). The rank values for aspect appear to contradict the information on use versus availability. However, data on use report only overall percentage of use, and taking behavior of individual animals into account; the 136 – 315° aspects receive the highest rank. Less than ⅓ of locations (405 of 1424) were in forested habitats (Table 3), and of these locations, forests > 250 years old received the highest rank.

For analysis within groups, we found a significant difference in mean elevation between calving time and the rest of the year for cows without calves, but not for cows with calves. For analysis within season, we found a significant difference in mean elevation for calving time but not for the rest of the year. Although sample sizes were smaller for calving time, both groups had a narrower range in elevation during calving and individual differences in elevation use were also higher during calving than the remainder of the year (Figures 2 – 5). Figure boxes represent the interquartile range containing 50% of the values, with a line showing the median value. Error bars represent the highest and lowest values, excluding outliers (extreme values). Most cows gave birth in alpine locations, in exposed areas free of snow. Of the 16 cows sampled, only cow #151 made extensive use of elevations below 1400 meters throughout the year (Figure 4).

Calving time for Telkwa Caribou ranged from 26 May until 10 June, and six Caribou calves were collared between 3 June and 10 June 1999. Five were males born to transplanted Caribou cows and one was a female calf born to the only resident collared cow. Average birth weight was 8.4 kg (range 6.9 – 9.4 kg). Three of the six calves died shortly after birth. One calf likely died from abandonment, whereas cause of

death for the second calf appeared to be avian predation, most likely Golden Eagle. Cause of death for the third calf was unknown. The calf had remains of what appeared to be milk curds in the stomach and small amounts of vegetation. However, membranes inside the hide appeared dry and indicated dehydration. No signs of predation or scavenging were evident. We found adult tracks, likely made by the mother, circling the carcass. During the first year after the transplant (1998), we observed five calves in the herd. The following year, we saw one yearling in the herd, as well as 12 new calves and one cow with an extended udder, indicating she recently had given birth and lost her calf. We observed eight calves during the 1999 October calf count. Recent surveys of the herd found 16 cows with calves in October 2003 and 23 the following year. In October 2005 ten cows with calves were counted. However, the decrease in cow/calf numbers from 2004 to 2005 may reflect fewer functioning radio collars in the herd during 2005, thus increasing the probability that some Caribou groups went undetected (G. Schultze, personal communication).

Discussion

The Telkwa Caribou Herd appears to select high elevation habitat with moderate slopes, which corresponds with earlier observations (van Drimmelen 1986*; Bill Holland, personal communication in Stronen 2000). The herd uses gentle to moderate slopes throughout much of the year, which is common for Woodland Caribou (Edmonds and Bloomfield 1984; Seip 1990*; Terry et al. 1996; Wood and Terry 1999). However, use of steep slopes is also reported (Hatler 1987*; Terry et al. 1996). Woodland Caribou have been found using southern/warm aspects (Edmonds and Bloomfield 1984; Warren et al. 1996), northern/cool aspects (Warren et al. 1996) or to show no apparent selection (Seip 1990*). Use also varies between years and seasons (Terry et al. 1996; Wood and Terry 1999). When in forested habitat the Telkwa Caribou Herd appears to select old forests, which corresponds with other studies (Cichowski 1993; Terry et al. 1996; Wood and Terry 1999; Apps and Kinley 2000*). Woodland Caribou in British Columbia have been classified into two ecotypes (Stevenson and Hatler 1985). The north-

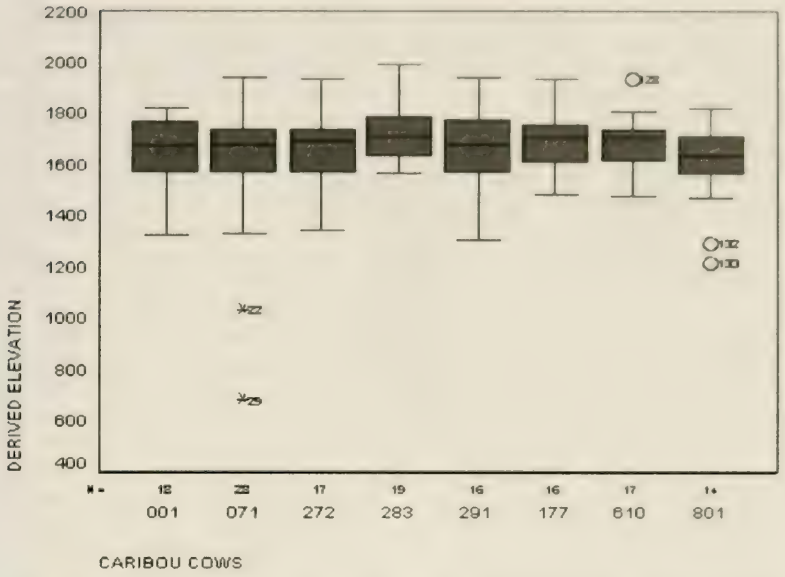

FIGURE 2. Barren cows' use of elevation all-year, 1999. Telkwa Mountains, British Columbia.

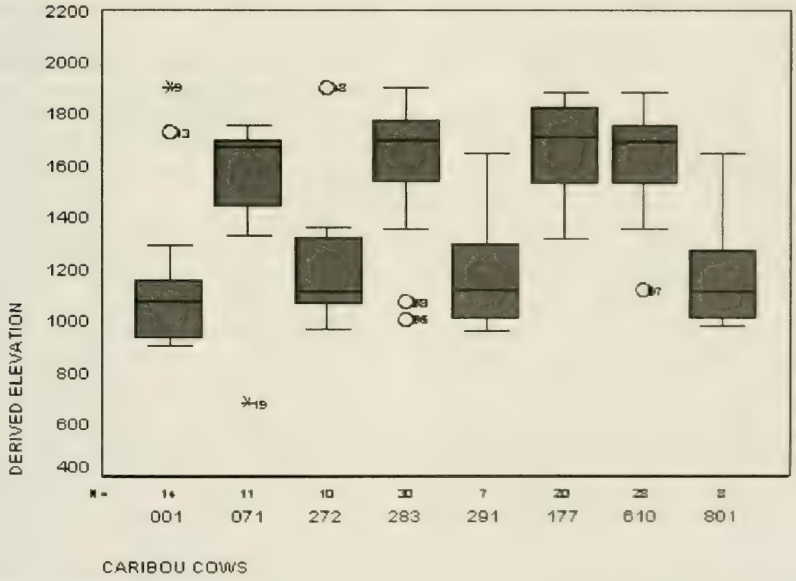

FIGURE 3. Barren cows' use of elevation at calving time, 1999. Telkwa Mountains, British Columbia.

ern ecotype (including the Telkwa Caribou Herd) depends primarily on terrestrial lichens during winter and the mountain ecotype depends more on arboreal lichens. Arboreal lichens are most abundant in old forest (Apps and Kinley 2000*), often on trees > 120 years old (Stevenson and Hatler 1985; Wood and Terry 1999). We found the Telkwa Caribou Herd in forested habitat only one-third of the time. However, divisions between arboreal- and terrestrial lichen-dependent groups are not absolute. The temporal impacts of icing, deep snow, and other environmental conditions may at times prevent Caribou from obtaining terrestrial lichens, making areas of arboreal lichens provisionally more important (van Drimmelen 1986*; Edmonds 1988; Cichowski 1993). Forests 141–250 years old received the highest use but the lowest rank. This is the most abundant forest age class (Table 3). Whereas the small number of Caribou during this study did not use this age class

in proportion to availability, the low rank does not equal avoidance or lack of importance. Future monitoring could also help clarify whether certain areas within this forest age class are locally important.

The difference in elevation use between barren and reproductive cows during calving season might be due to reproductive status. There are, however, wide differences within each group. As four of eight barren cows remained at high elevations (which presumably meant forgoing nutritional opportunities, at least in spring/early summer), this could be an antipredator strategy employed regardless of reproductive status. Based on this study, possible antipredator tactics for protecting a calf can not be distinguished from those that cows seem to use for their own protection. Edmonds and Smith (1991) reported that cow/calf pairs localised movement to relatively small geographic areas in early June (1-15) and did not increase the size of their ranges until after July. The Telkwa Caribou displayed similar behaviour, as cow/calf pairs in the Telkwa Herd remained relatively stationary until the middle of July. Subsequently, some pairs made long distance movements (one pair moved 50 km over a few days). The calving time for Telkwa Caribou corresponded to that reported by Edmonds (1988) for westcentral Alberta. As only one birth from a resident Caribou was recorded (10 June), it was not possible to examine any differences between transplant and resident animals.

Some cows in the Telkwa Caribou Herd appeared more sensitive to fixed-wing aircraft during the first couple of weeks post-calving than during the rest of the year, but we noted a wide range in behaviour. Cichowski (1993) reported that most adult females were found alone on ridge tops during calving. Two Telkwa cows calved on the top of a rocky ridge and were joined by two other cows with calves in the middle of June. The ridge had few access points but biophysical information suggests low potential for lichen production. All four calves were found alive in October. The use of ridges may be a trade-off between predator avoidance and the availability of abundant high protein food (Bergerud and Miller 1984). Cichowski (1993) found that most calving sites were within 10 km of previous calving sites and Seip (1990*) reported many Caribou use the same calving locations each year. We could not analyse fidelity to calving areas within the Telkwa Herd and it would take several years before this could be assessed. Caribou calving areas could change from year to year as an antipredator strategy (Bergerud and Miller 1984), and Valkenburg et al. (1988) warned against making management decisions based on Caribou calving areas located during narrow time intervals. However, previously known calving areas identified by the Traditional Ecological Knowledge of the Wet'suwet'en First Nation (B. Holland, in Stronen 2000) should be considered when making management decisions, as this information is based on years of observation and would indicate fidelity to specific calving sites.

Small sample size precluded analysis of calf mortality for the Telkwa herd but suggested that avian predation was a factor. Recruitment data from November 1998 to April 2000 seemed to indicate that low production of calves was a factor of equal or higher importance than the loss of calves. If the low recruitment of calves was due to calf predation, a higher frequency of Caribou cows with extended udders but without calves would be expected. Females without calves commonly shed their antlers in March and April and exhibit fresh antler growth during the calving period, whereas pregnant females shed their antlers near calving in May and June (Bergerud 1980). During our surveys at calving time, many cows exhibited fresh antler growth, indicating that they were not expecting a calf that year. The Caribou transplanted from the Sustut Caribou Herd would be expected to show pregnancy rates comparable to those of other populations when they arrived, and reported pregnancy rates usually range from 80% to 90% (Bergerud 1980; Seip 1990*; Edmonds and Smith 1991). It is possible that stress related to capture, immobilization, and transplant may have caused abortions or fetal absorptions, or that a large number of the cows were by chance not pregnant. In addition, there may not have been enough bulls to achieve normal pregnancy rates for the Telkwa herd during the first years. At least one resident mature bull was present in the herd during 1998 but due to difficulties associated with movement and collaring of adult bulls only younger males were translocated to the Telkwa Mountains.

Human activities such as recreation and resource extraction may also influence Caribou habitat use. Van Drimmelen (1986*) expressed trepidation over snowmobiling on the winter ranges of the Telkwa Herd and this has been a concern for over 25 years (Bustard 1977*). The presence of dogs may also cause Caribou to avoid otherwise useful habitat. This is particularly important during calving time, when cows may be extra sensitive to disturbance (Bergerud and Miller 1984). Need for information related to species translocations and/or small remnant populations will increase in the future. Where habitat availability is poorly estimated it may be particularly important not to label habitats and resources, which may be important in the long term, as avoided. We chose Johnson's (1980) method because it is relatively insensitive to decisions on what constitutes available habitat for the Telkwa Caribou Herd. If habitat components are used in proportion to availability, the rank ordering of use and availability will be the same. However, the converse is not necessarily true; the use and availability proportions could be different across habitat components, while still having the same rank, thus resulting in high Type 2 errors (where a difference in proportional selection is not detected) (Alldredge and Ratti 1986,

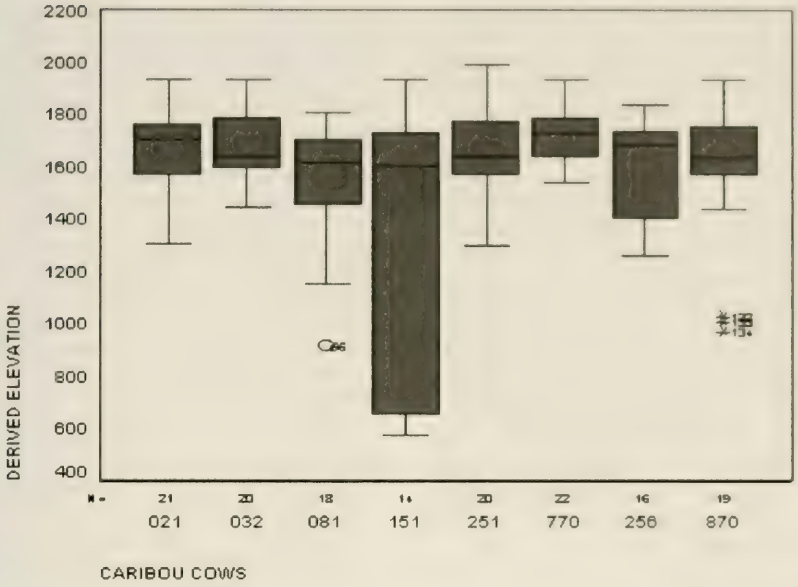

FIGURE 4. Reproductive cows' use of elevation all-year, 1999. Telkwa Mountains, British Columbia.

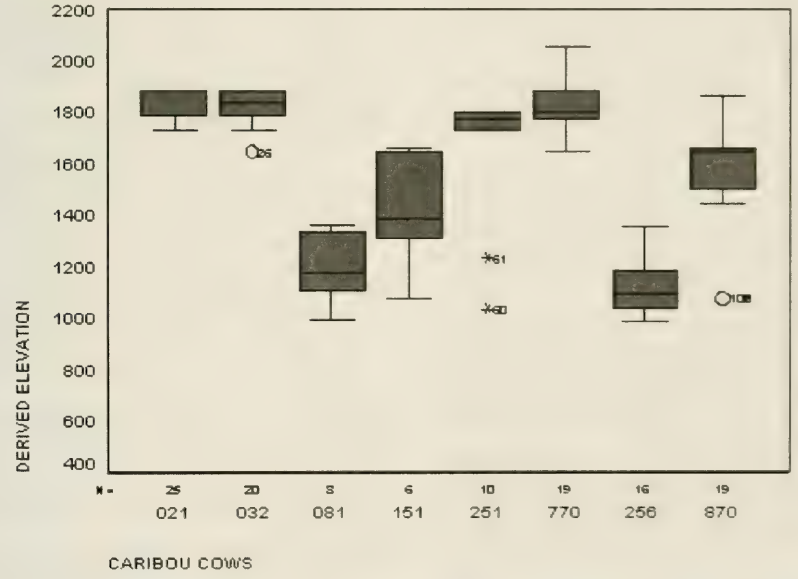

FIGURE 5. Reproductive cows' use of elevation during calving time, 1999. Telkwa Mountains, British Columbia.

1992). A bias may also occur against small habitat patches when the size of error area for locations [here ± 300 m] is independent of habitat patch size (Rettie and McLoughlin 1999). Many wetlands in our study area were too small to be captured in Forest Cover data and Houwers (1996*) reported that distribution of arboreal lichens in the Telkwa Mountains was patchy. These two habitat units, too small to be noted by our analysis, may be vital for long-term survival of the Telkwa Caribou Herd. The size of habitat required by Caribou to avoid predation may be significantly greater than the amounts required to obtain sufficient forage (Stevenson et al. 1994*; Seip and Cichowski 1996), and requirements for predation avoidance could be 10 times larger (Bergerud 1980). It is theorized that the Telkwa Mountains could support approximately

300 caribou (van Drimmelen 1986*). Given sufficient habitat and calf survival the herd could recover to historic numbers. At present, the translocation appears to have been successful in establishing a self-sustaining Caribou herd in the Telkwa Mountains.

Acknowledgments

The Habitat Conservation Trust Fund, Forest Renewal BC, the British Columbia Ministry of Environment, and a Graduate Research Scholarship from the Faculty of Environmental Design, University of Calgary, provided funding for this study. Staff at the British Columbia Ministry of Environment in Smithers assisted with fieldwork, and G. Schultze provided survey data from 2000 to 2005. We thank J. Warren and other staff at the GIS-section for help with all GIS-related work. Northern Lights Air piloted fixed-wing telemetry flights, and Canadian Helicopters piloted flights to capture caribou calves and investigate mortalities. An anonymous reviewer provided helpful comments on the manuscript.

Cota-Sánchez, J. Hugo, and Kirsten Remarchuk. 2007. An inventory of the aquatic and subaquatic plants in SASKWater canals in central Saskatchewan, Canada, before and after the application of the herbicide Magnacide. Canadian Field-Naturalist 121(2): 164–167.

This study focuses on the floristic composition of aquatic and semi-aquatic plants in the SASKWater canal system and their potential effect on irrigation systems. A checklist, evaluation, and synthesis of the species identified in this survey before and after the application of the herbicide Magnacide are provided, in addition to a brief discussion of the environmental effects of Magnacide. Thirty-three species in 26 genera within 20 plant families were identified. Two unidentified green algae were also collected. Common aquatics (i.e., green algae, *Potamogeton* spp., *Alisma gramineum*, *A. plantago-aquatica*, *Ceratophyllum demersum*, and *Myriophyllum sibiricum*) combined with debris from terrestrial plants were the primary contributors to blockage of irrigation drains. In general, the concentration of Magnacide used in this study had a minor effect on aquatic plant diversity, but effectively reduced plant density. However, the long-term effects of pesticides on the surrounding aquatic and terrestrial environments of the SASKWater irrigation system are unknown.

Key Words: aquatic plant inventory, environmental effect, SASKWater canals, Magnacide, acrolein, Saskatchewan.

Plants are vital to the function of aquatic ecosystems for their role in providing food, oxygen, and habitat for other organisms. However, floating and submerged vegetation along with debris from terrestrial plants may be problematic in different types of water bodies. For example, in shallow lakes, profuse plant growth creates dense mats that prevent the regular movement of watercraft. In addition, aquatic plants, including algae, can significantly reduce the aesthetic value of water bodies. Furthermore, rapid growth of vegetation and deposition of debris in irrigation canals can result in a decline in water flow rates and a subsequent inability to supply water to crops. Hence, the removal of selected aquatic species via physical or chemical methods may be required to improve ecosystem function, aesthetic value, and availability for human consumption.

Aquatic plants can be placed into four broad categories: (1) algae, (2) floating-leaved, (3) submerged, and (4) emergent plants (Shelton and Murphy 1989). Of the four categories listed above, algae are of the greatest concern in canal systems because of the likelihood of interfering with water flow. Algae grow profusely in slow moving, shallow water. Floating-leaved and submerged plants are rooted, with the foliage at or below the water surface. Flowing water or disturbance, such as wind, can uproot plants leading to subsequent obstruction of water flow. Finally, emergent species typically grow in shallow, fluctuating water, such as drainage ditches, canals, rivers, periphery of water bodies, and ponds. Plants in this category are of minor concern in canal systems and in some cases may prevent non-aquatic plant debris from entering the system.

Aquatic species impede water flow by clogging gates, intake screens, valves, and pumps in irrigation and drainage channels (Lancar and Krake 2002). As a consequence, localized flooding may result under high water conditions. In addition, Holm et al. (1969) indicate that abundant vegetation in canals can lead to an excessive loss of water through evapotranspiration. pondweed (*Potamogeton* L.), Milfoil (*Myriophyllum sibiricum*), Canada Waterweed (*Elodea canadensis*), wild celery (*Vallisneria* L.), and American Eel-grass (*Zostera marina* L.) are a few of the problematic coarse or large species in shallow aquatic environments (Lancar and Krake 2002).

Of particular interest to this study are aquatic taxa that interfere with canal irrigation systems in central Saskatchewan. Accelerated growth of plants in SASKWater canals restricts the amount of water available for irrigation. Given the clogging effect of aquatic plant growth on water flow, agricultural canals were treated with Magnacide, a volatile algaecide and aquatic herbicide, in which the active ingredient is acrolein (Scorecard 2006*). Acrolein contains two functional groups, a reactive double bond and an aldehyde group (Nordone et al. 1996) and is, in turn, toxic to some organisms (Albariño et al. 2007). However, it is widely used in agricultural canals and water bodies as an herbicide to control aquatic weeds (Burland et al. 1984; Sangodoyin and Smith 1996). The use of high concentrations of acrolein could pose a significant risk to aquatic environments (Nordone et al. 1996); therefore, the controlled application and use of Magnacide and other

herbicides is highly recommended. Previous studies have shown that toxic residues deposited in soils and water bodies have detrimental effects in the life cycles of local flora and fauna (Sangodoyin and Smith 1996). Thus, even though several sources, e.g., Sangodoyin and Smith (1996); Nordone et al. (1996); Albariño et al. (2007), claim that the transient use of acrolein in agricultural waters at minimal amounts has no negative impact in natural aquatic environments, rigid control must be enforced to prevent ecological damage.

In this study, we investigated the floristic composition of aquatic and semi-aquatic plants in the SASKWater canal system and their potential effect on irrigation systems. Our study is a contribution to the knowledge of Saskatchewan aquatic and sub-aquatic flora and provides a preliminary assessment and synthesis of the species identified prior to and after the application of Magnacide. The potential effect of Magnacide on aquatic flora is also discussed.

Methods

Compared to most wetland inventories, this survey covers a limited geographic area and a restricted range of wetland flora. The site selection and sampling strategy were designed to survey all major areas of the SASKWater canal system to be evaluated in terms of aquatic vegetation within the Saskatoon Southeast Water Supply Project Location Plan (Brightwater-Blackstrap-Zelma Reservoir areas; 51°25' to 52°55'N, 106°15' to 107°00'W). This system irrigates an estimated area of 20 120 acres. The survey sites include locations of Magnacide application by SASKWater personnel at intake screens. Acrolein was directly applied to water in strategic sites to control submersed, floating and emergent aquatic weeds. The herbicide was applied at a concentration of 2.5-5.0 ppm/30 minutes every two weeks from June through August 2005 in an attempt to eradicate aquatic species with excessive growth rates (J. Mander, SASKWater, personal communication). Surveys were conducted before and after the chemical treatment to determine the effect of Magnacide on the taxonomic richness and occurrence of aquatic plants in the canal system. Plant collections were conducted in 25-50 m areas before and after the point of application. Plants were pressed and identified in the herbarium of the University of Saskatchewan (SASK) using several local and regional references (Hotchkiss 1972; Larson 1993; Johnson et al. 1995; Moss 1996; Vance et al. 1984; Royer and Dickinson 1999). The plants collected were prepared as voucher specimens to serve as a permanent reference of this study in the SASK collection.

Results and Discussion

The survey indicates that the taxonomic composition of the SASKWater canals includes a total of 33 species in 26 genera and 20 plant families (Table 1). In addition, two different, unidentified, algae were collected (Table 1). Our survey also indicates that no plant species were eradicated from the sites as a result of Magnacide application; that is, the same species were identified before and after the treatment. However, the plant density was noticeably lower after the treatment with Magnacide. Various submerged species including *Potamogeton richardsonii*, *P. pectinatus*, and the unknown green algae were present in most of the sites surveyed. Other aquatics, e.g., *Elodea canadensis* and *Lemna trisulca*, were less frequent and accounted for a smaller proportion of plant biomass in the canal system. Emergent species in the Cyperaceae, Equisetaceae, and Asteraceae do not appear to play a role in impeding water flow, but floating debris from non-aquatic taxa, such as *Melilotus albus* and *Hordeum jubatum*, contributes to the clogging of intake screens throughout the canal system.

Based on this survey, it is not possible to determine a single species that adversely affects water flow by clogging intake screens in the SASKWater canal systems. A combination of common aquatic plants (*Potamogeton* spp., *Alisma gramineum*, *A. plantago-aquatica*, *Ceratophyllum demersum*, and *Myriophyllum sibiricum*), which are frequently dislodged by flowing water or wind, are the primary contributors to blockage of drains and intake screens. The presence of large, coarse water pondweeds such as *Potamogeton* spp. and other filamentous species in SASKWater canals is undesirable because their accumulation affects the regular water flow. A similar situation has been reported in the Alberta irrigation systems (Burland and Catling 1986). In addition, green algae are common and are presumably the greatest problem in clogging the intake screen systems because of their filamentous nature and massive growth. Furthermore, some plants or fragments from non-aquatic plants, particularly *Melilotus albus* and *Hordeum jubatum*, are involved in reducing water flow because the species tend to concentrate near the uptake areas, especially in the vicinities of mowed ditches along the canals.

Since this survey is mainly concerned with the floristic composition of the SASKWater canal system and the probable effect of some species on irrigation canals, only general comments can be made regarding the chemical treatment and subsequent effect in the aquatic and subaquatic plants. In general, the use of Magnacide at the concentration previously specified appears to have a minor effect on aquatic plants because species diversity before and after the application remained similar. This suggests that the amount of chemical applied is too low to notably reduce the growth and development of aquatic plants and possibly other non-target organisms. Acrolein is a contact herbicide; therefore, the root system is not damaged and plants quickly resume growth. This leads to the frequent re-application of acrolein (J. Mander, SASKWater, personal communication). Other studies, [e.g., Bowmer and Sainty (1977)], have shown that acrolein is effective in controlling aquatic plant growth, but no concentration rates are given. On the other hand, Sangodoyin and Smith

TABLE 1. Taxonomic list of the inventory of plants in the SASKWater canal system in south central Saskatchewan. The arrangement is alphabetical by family, then by genus and species.

Family	Species	Common Name
Characeae	Unknown green algae	
	Chara L.	
Alismataceae	*Alisma gramineum* Lej.	Narrow-leaved Pondweed
	Alisma plantago-aquatica L.	Broad-leaved Water Plantain
Apiaceae/Umbelliferae	*Sium suave* Walter	Water Parsnip
Asteraceae/Compositae	*Symphiotrichum lanceolatum* (Willd.) G.L. Nesom subsp. *hesperium* (A. Gray) G.L. Nesom	Western Willow Aster
Ceratophyllaceae	*Ceratophyllum demersum* L.	Hornwort
Cyperaceae	*Carex rostrata* Stokes	Beaked Sedge
	Eleocharis acicularis (L.) Roem. & Schult.	Needle-Spike Rush
	Eleocharis palustris (L.) Roem. & Schult.	Common or Pale Spike-Rush
	Schoenoplectus acutus (Muhl. ex Bigelow) Á. Löve & D. Löve	Great Bulrush
	Schoenoplectus tabernaemontani (C.C. Gmel.) Palla	
	Scirpus microcarpus J. & K. Presl.	Small-fruited Bulrush
Equisetaceae	*Equisetum palustre* L.	Marsh Horsetail
Fabaceae/Leguminosae	*Melilotus albus* Medik.	White Sweet Clover
Halogaridaceae	*Myriophyllum sibiricum* Kom.	Water Milfoil
Hydrocharitaceae	*Elodea canadensis* Michx.	Canada Waterweed
Lamiaceae/Labiatae	*Lycopus asper* Greene	Water Horehound
Lemnaceae	*Lemna trisulca* L.	Duckweed
Onagraceae	*Epilobium ciliatum* Raf.	Northern Willow Herb
	Oenothera biennis L.	Yellow-Evening Primrose
Poaceae/Graminae	*Glyceria grandis* S. Watson	Manna Grass
	Hordeum jubatum L.	Wild Barley
	Phalaris arundinacea L.	Reed Canary Grass
Potamogetonaceae	*Potamogeton filiformis* Pers.	Leafy Pondweed
	Potamogeton pectinatus L.	Sago Pondweed
	Potamogeton richardsonii (Benn.) Rydb.	Clasping Leaf Pondweed
	Potamogeton vaginatus Turcz.	Large-sheath Pondweed
	Potamogeton zosteriformis Fern.	Flat-stemmed Pondweed
Ranunculaceae	*Ranunculus aquatilis* L.	Thread-leaved Buttercup
Salicaceae	*Salix exigua* Nutt.	Narrow-leaved Willow
Sparganiaceae	*Sparganium* sp. L.	Bur-Reed
Typhaceae	*Typha latifolia* L.	Common Cattail
Zannichelliaceae	*Zannichellia palustris* L.	Horned Pondweed

(1996) caution that low concentrations of pesticides and agricultural chemical on surface waters have potential effects on fisheries and aquatic environments, but conclude that Canadian water sources in general exhibit concentrations of pesticides below the guideline limits, which suggests the proper use and handling of pesticides and herbicides in Canada. Nonetheless, more detailed research is required to draw conclusions on water quality issues.

Considering the losses and adverse effects to farming activities caused by obstructed canal systems, the control of aquatic plants is necessary in water bodies, particularly in areas with intake screens, so that irrigation systems can be most efficiently utilized. In addition to the chemical methods currently used for the eradication of aquatic plants, new research to implement a biological control program (involving perhaps an herbivorous species) of aquatic plants in irrigation canals should be conducted. Since numerous non-aquatic species clog irrigation systems, in our view, the most effective, environmentally friendly, and inexpensive strategy for maintaining levels of water flow for irrigation is to periodically manually clean intake screens and surrounding areas. Nonetheless, cautious and planned applications of chemicals such as acrolein (Bowmer and Sainty 1977), Endothall (Sisneros et al. 1998), and Hydrothall (Corbus 1982) may be effective to control excessive growth levels of species such as *Potamogeton pectinatus* and filamentous algae species.

Since several native, relatively poorly represented species are characteristic of these ecosystems, consistent monitoring is recommended to preserve wild natural resources. Furthermore, the long-term effects of pesticides on the surrounding aquatic and terrestrial environments of the SASKWater irrigation system are unknown. The current challenge is to assess the use of herbicides, in particular the long-term effect and impact of Magnacide residues, in the water quality, environment, and diversity of the wetland flora and fauna in Saskatchewan and other Canadian ecosystems.

Acknowledgements

We thank SASKWater personnel, in particular K. Berkers for help with surveys, J. Mander for comments and for showing the canal system, and two anonymous reviewers for their comments on the manuscript. We also thank the personnel of the Herbarium of the University of Saskatchewan (SASK) for their assistance.

Mercer, Sarah C., Glenys D. Gibson, and Michael J. Dadswell. 2007. Life history of the Marine Isopod *Cyathura polita* in the Saint John River estuary, New Brunswick: A species at the northern extent of its range. Canadian Field-Naturalist 121(2): 168-177.

The marine isopod, *Cyathura polita*, inhabits estuaries on the east coast of North America from the Gulf of Mexico to the Bay of Fundy, Canada. We studied *C. polita* in the Saint John estuary to test for potential differences in life history that might occur because of the northern location of the population. In the Saint John, based on our interpretation from a six-month sampling program (May-October), the population exhibits a three-year life cycle, one year longer than more southern populations, and stretching over four summers. Our study supported the occurrence of protogynic hermaphroditism. After two summers as juveniles, individuals matured as females during their third summer, then displayed sex reversal by becoming males that fall, and finally reproducing as males in their fourth summer of life before death. Mean length of *C. polita* from the Saint John was greater than individuals from more southern populations (females, 13.8 ± 2.14 mm; males, 16.3 ± 2.41 mm). Annual brood release occurred in late July-early August. Mean fecundity of females was 53.2 ± 18.9 embryos per brood, which was greater than found in southern populations. *Cyathura polita* is rare in Canada and is known only from the Saint John and along the northern shore of the Bay of Fundy to the border of the United States.

Key Words: Isopod, *Cythura politica,* growth, reproductive cycle, fecundity, protogynic hermaphroditism, status, St. John River, New Brunswick.

Our knowledge of life history evolution depends on understanding intraspecific variation in life history traits, such as those correlated with latitude. *Cyathura polita* (Stimpson, 1855) is a benthic isopod that occurs in estuaries along the Atlantic coast of North America from the Gulf of Mexico to the Bay of Fundy, Canada (Burbanck et al. 1979), and is an appropriate model for such a study. Latitudinal variations in life history traits have been demonstrated for *C. polita* populations from Florida to Cape Cod, and include adult size and life span (Burbanck and Burbanck 1979). Latitudinal differences in life history traits have been described in the common cyathuran of the eastern Atlantic, *Cyathura carinata*, among populations from Portugal to Sweden (Bamber 1985; Olafsson and Persson 1986; Marques et al. 1994; Cruz et al. 2003). In the present study, we investigated life history characteristics of *C. polita* for its northernmost known population in the Saint John River estuary, New Brunswick.

Cyathurans are interstitial isopods that live in burrows and feed on detritus and algae in the sediment (Burbanck 1959). They are eurytopic animals, tolerating wide fluctuations in conditions such as temperature and salinity, an adaptation suitable to estuaries. They are also an important indicator organism for healthy estuarine ecotones because they are usually present only in unpolluted waters (Burbanck and Burbanck 1979). Cyathurans in general do not swim as adults nor do they have a pelagic larval stage, resulting in populations that are relatively immobile, sessile and disjunct. According to Burbanck (1959, 1962a, b), *C. polita* inhabits estuaries where fresh and salt water mix over stable sediment containing gravel, silt and detritus. They are obligatory aquatic animals and cannot withstand long periods of dryness (Burbanck and Burbanck 1979). Often *C. polita* are located in transitional zones where cattails (*Typha*) and salt marsh grasses (*Spartina*) meet along the shoreline (Burbanck 1962b). They are an important food for ducks and fishes (Burbanck and Burbanck 1979; Dadswell 1979).

The life cycle of *C. polita* varies with latitude (Burbanck and Burbanck 1979). In southern populations, the life cycle duration is generally one year. In Florida, young are released from May to October, and grow over the winter until they mature and produce young the following spring and summer. Most southern cyathurans die at the end of their second summer (Kruczynski and Subrahmanyam 1978). In more northern locations, such as Cape Cod, the young are released in early summer (late June or early July), grow rapidly in the fall, and produce young the following year. In these populations some cyathurans die at the end of their second summer while others may survive a second winter and reproduce the following year, often exhibiting protogynic hermaphroditism (Burbanck and Burbanck 1979).

Cyathuran females carry their embryos in a ventral marsupium made of overlapping pairs of oostegites (Stromberg 1972). The embryos develop in the marsupium until they hatch from a vitelline membrane and are released into the environment as juveniles. This method of reproduction permits detailed study of fecundity and development in cyathurans, making the species an excellent model for life history studies.

Cyathura polita has been studied extensively in the United States, particularly in the southern states (Burbanck and Burbanck 1979). The Saint John River estuary and along the north Bay of Fundy shore to the United States border are so far the only known occurrences of *C. polita* in Canada, and these populations are located at the northern extent of its range (Burbanck et al. 1979, Atlantic Reference Center, St. Andrews, New Brunswick). We investigated the life history of *C. polita* in the Saint John River estuary, and compared these data to published observations to explore the hypothesis that northern cyathurans would exhibit differences in life history relative to those at southern latitudes. We suspected that, with probable slower growth in this population, body size of adults would be greater because of delayed maturity and the larger females would carry more embryos. Also, since this is one of the few Canadian populations of an organism which has poor powers of dispersal caused by its non-swimming life style and a brooding reproductive method, it may be important to characterize its life history for future reference under the Species at Risk Act. Finally, the Saint John River estuary is a unique habitat in Canada containing elements of Virginian, coastal marine ecosystems in the summer-warm shallows (Bousfield 1962; Burbanck et al. 1979; Dadswell 1979), boreal, marine species in its deep, fjord-like basins (Trites 1960; Carter and Dadswell 1983) along with the wide range of freshwater, diadromous, and marine species typically found in Atlantic Canada (Rogers 1936; Bousfield 1962; Gorham 1965; Gillis 1974).

Study Area and Methods

Samples of *Cyathura polita* were collected from the subtidal shore of the lower Saint John River estuary from four stations: Bell Point, Westfield Beach, Summerville and Millidgeville (Figure 1). This region is the junction between the Bay of Fundy and the Saint John River and both estuary outflow and tidal inflow are inhibited by a sill at the Reversing Falls. As a result, there are large fluctuations in salinity because of freshwater discharge, and inside the estuary tidal range is reduced to 0.5 m and summer surface temperatures are higher than in the Bay of Fundy (Metcalfe et al. 1976). The Saint John River has a salt wedge estuary combined with deep, fjord-lake basins, and surface salinities at the seaward end fluctuate throughout the year, falling to 0% during spring freshet and increasing to 20% during low freshwater flow (Metcalfe et al. 1976).

Samples were collected approximately bi-weekly, usually at low tide, from 29 May to 27 August 2004, with an additional collection on 10 October 2004. Samples of *C. polita* were collected randomly by removing the surface substrate from subtidal sites in water depths of 20 to 150 cm. Substrate was collected with a shovel, and sieved through 1 mm or 0.25 mm mesh. The smaller mesh size was used to capture juveniles too small to be retained by the larger mesh. Approximately 30 adults and 30 juveniles, if possible, were collected from each location during a sampling effort. Individuals were fixed on the day collected in 10% formalin buffered in sea water and transferred to 70% isopropyl alcohol within three days. On each collection date at each station, the water temperature at 0.5 m depth was measured using a mercury thermometer, and a 1L sample of surface water was collected for salinity measurements later in the laboratory. Sediment samples from each station (1L) were collected on 17 July 2004.

Salinity was measured using an YSI 30 Salinity meter, after calibration with a mercury thermometer. Sediment samples were analyzed for proportions of gravel, sand, and silt, using a sieve series where gravel was <38.1 mm, sand <2.0 mm, and silt <63 μm (Miall 2000).

Within a few days of capture, the total length of all individuals was measured to the nearest mm from the base of the antennae to the tip of the telson. Measuring the total body length was preferred to estimating size from prosomal length (Bamber 1985), for comparison with other literature on *C. polita*. Males were distinguishable by the presence of an appendix masculina on the second pleopod; females could be accurately distinguished only when with oostegites forming a brood pouch or marsupium (Figure 2). Individuals without these sexual dimorphisms were considered to be juveniles.

All gravid females with intact marsupia were analyzed for number and size of embryos. Embryos were removed from marsupia and classified into four stages of development based on electron microscopy (Mercer et al., *in press*): Class 1 embryos were round and contained within two membranes, the chorion and vitelline membranes; Class 2 embryos were elongated and showed differentiation of the three body regions (head, thorax, abdomen), but lacked differentiation of the appendages; Class 3 embryos were still housed within the vitelline membrane, but had considerable differentiation of appendages and head; and Class 4 embryos were hatched from the vitelline membrane and had well-differentiated appendages. Embryos were measured with a compound microscope to the nearest 17 μm.

Adults and embryos were prepared for scanning electron microscopy (SEM) with primary fixation in 2.5% glutaraldehyde (1 hr), followed by a post-fixation in 1% osmium tetraoxide (4 hrs, both fixes in 0.1M

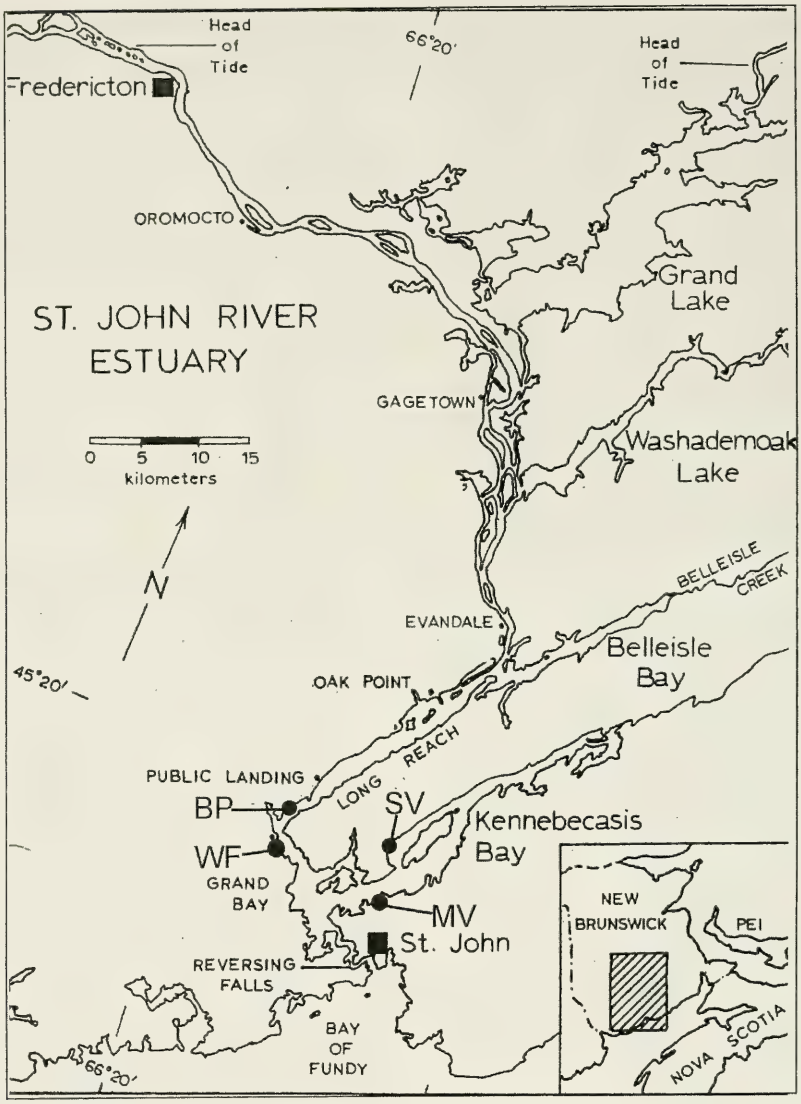

FIGURE 1. Map of the Saint John River estuary, with the four study locations indicated. BP = Bell Point; WF = Westfield; SV = Summerville; MV = Millidgeville.

cacodylate buffer in seawater). Tissues were dehydrated in an ascending ethanol series, critical point dried using a Bio-Rad E3000 critical point drier with liquid CO_2, and sputter coated with a Technics Hummer II sputter coater. Samples were viewed with a JEOL 5600LV Scanning Electron Microscope at 10kV.

Statistics were estimated with MINITAB 14, Microsoft Office Excel 2003, and SPSS 12. Graphs were plotted in Excel and SigmaPlot 9.0. Images were manipulated for size in Corel PhotoPaint 9 and labelled with CorelDraw 9.

Results

Water temperature, salinity and substrate were compared among all stations. For most of the study period water temperature ranged between 15 and 20°C (mean 19°C), with the highest temperature of 28°C on 17 July 2004 (Mercer 2005). Water temperatures at the four stations were similar on each collection date (one-way ANOVA, $P = 0.993$). Surface salinity ranged from 0.2 ppt in spring to a maximum of 6.6 ppt during mid-summer (Mercer 2005). However, mean salinity differed among the four stations (one-way ANOVA,

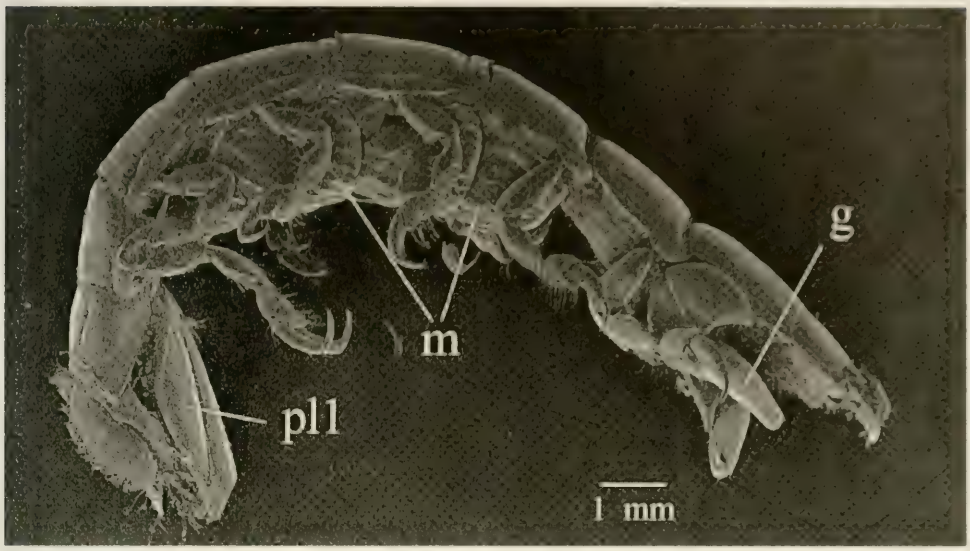

FIGURE 2. Scanning electron micrograph of a female *Cyathura polita* with marsupium, collected from the Saint John River during the summer of 2004. Symbols are: g = gnathopod, m = marsupium, pl1= 1st pleopod.

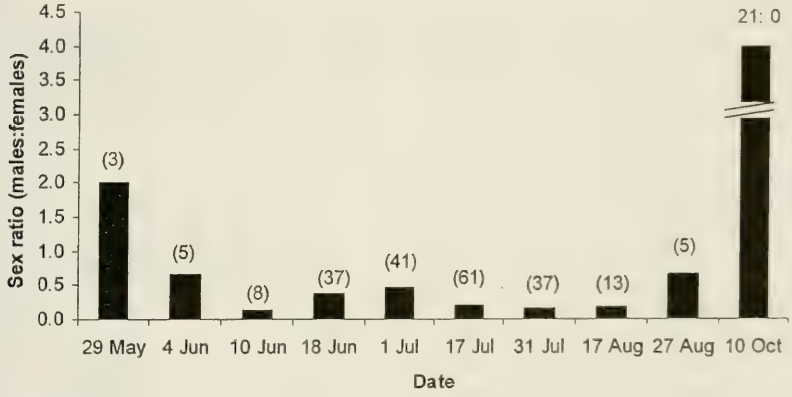

FIGURE 3. Male to female sex ratio of *Cyathura polita* during the study period in the Saint John River estuary. Data were pooled from four stations, and sample size (*n*) is given in brackets above each column. On 10 October, most adult isopods collected were male, resulting in a different scale, thus the sex ratio is given above the bar.

$P < 0.001$). Mean salinities at Bell Point (0.69 ± 0.31 ppt) and Westfield (1.5 ± 0.86 ppt) were similar (Fisher's 95% CI of -0.35, 0.78), while Millidgeville (4.7 ± 1.3 ppt) and Summerville (4.9 ± 1.5 ppt) were comparable (Fisher's 95% CI of -0.94, 0.19).

Sediment composition varied among the four study sites but all generally consisted of easily drained substrates (no anoxia; Mercer 2005). Bell Point had the highest gravel content of the four (84.5%), with little sand (15.1%) and hardly any silt (0.4%). Westfield had the highest percentages of sand (66.4%) and silt (7.3%) and the least amount of gravel (26.3%). Millidgeville contained more gravel (55.9%) than sand (43.5%) and very little silt (0.6%). Summerville was similar to Millidgeville with abundant gravel (47.1%) and sand (51.5%) and little silt (1.4%).

The sex ratio of *C. polita* varied during the study period, from a male:female ratio of 2:1 in May, declining to 0.5:1 in July, and increasing to 21:0 in October (Figure 3). In late spring, numbers of males exceeded females and large juveniles (probably maturing females) were present (Figure 4). From early June to the end of August, there were more females than males. Small, free-living juveniles, 2 to 3 mm in length, were first observed on 31 July 2004 numbers of presumably recently released from female marsupia. By the end of August, few distinguishable adults were collected at any station (Figure 4), but there were many

large juveniles (probably adults without secondary sexual characteristics). In October, despite the rarity of males during late August, there was an abundance of relatively large males (Figure 3).

Over the entire study, *C. polita* in the Saint John River estuary were an average of 10.1 ± 4.02 mm long, although the mean length varied among stations (Table 1). The mean length of all females collected was 13.8 ± 2.14 mm (n = 163) while males averaged 16.3 ± 2.41 mm (n = 68). Males were similar in length at all stations, as were females (Table 1; one-way ANOVA). Mean length of individuals collected from Bell Point and Millidgeville over the study period were similar, but isopods from both stations were significantly longer than those from Westfield and Summerville largely because the size of juveniles varied among stations (Table 1; one-way ANOVA). For three stations, mean juvenile length averaged 10.82 ± 2.50 mm while juvenile cyathurans from Summerville were smaller (8.60 ± 2.49 mm; Table 1). Most *C. polita* collected at Summerville throughout the study period were juveniles. This fact was highlighted when comparing the size of juveniles at Summerville (8.60 ± 2.49 mm in length) to the size of all individuals collected at Summerville throughout the study (8.71 ± 2.92 mm).

Seasonal changes in body length were estimated by comparing lengths of *C. polita* from each collection date, after sorting individuals by sex and reproductive stage (Figure 4). Since the physical characteristics were relatively similar among all stations growth data were pooled to assess life history. Females (with oostegites) were observed from 29 May to 27 August. Mature males were observed throughout the study, with peak abundance in late spring and early fall. Newly-released juveniles were first observed on 31 July and were abundant into the fall.

Cohort growth was estimated by comparing the mean length of each group of cyathurans at each collection date over the entire study period (Figure 5). Growth was estimated by extrapolating the mean length of each cohort in October back to the mean length of the next cohort in May. These estimates suggest that cyathurans from Saint John have a three-year life cycle, which spans four summer seasons. Young juveniles (Age 0) released from the marsupia at the end of July had a mean body length of 2.7 ± 0.25 mm and averaged 7.5 mm by October. Young juveniles grew approximately 0.07 mm/day, the fastest of all groups, where growth was represented by: $y = 0.068x - 11.9$ ($R^2 = 0.99$). The second cohort of juveniles (Age 1) had a mean length of 8.8 ± 3.4 mm in May and grew approximately 0.02mm/day were growth was represented by: $y = 0.018x + 6.44$ ($R^2 = 0.22$), resulting in a mean length in October of 12.4 ± 1.90 mm. Mature females (Age 2) were 11.0 mm mean length in May, and grew slowly at a rate of 0.01 mm/day where growth was represented by: $y = 0.009x + 11.3$ ($R^2 = 0.05$)

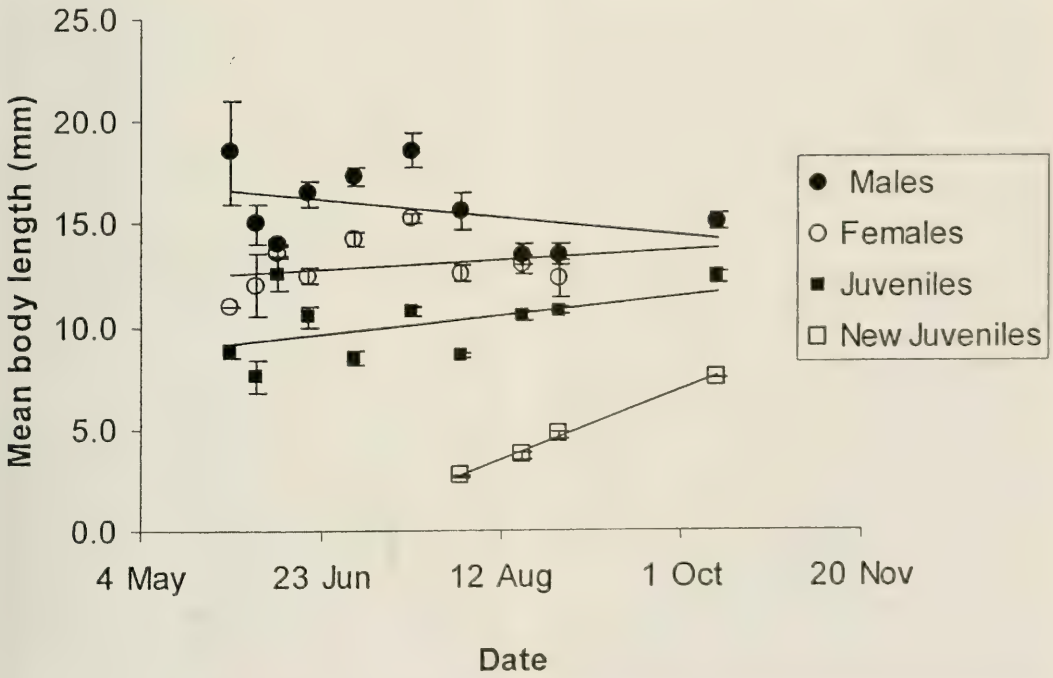

FIGURE 5. Mean length of *Cyathura polita* from the Saint John River estuary pooled from all stations at each sampling interval during the summer of 2004 and grouped by sex and reproductive stage. Vertical bars are standard deviations.

was very different from that of juveniles and females. Males (Age 3) were largest at the end of May (mean length 18.5 ± 3.54 mm), but smaller in October (mean length 15.1 ± 1.95 mm). A bi-modal size distribution during the growing season suggests the die-off of larger and older males in early summer, and the addition of new, smaller males in the fall as females underwent protogynic sex change or some large juveniles matured as males.

Other studies noted latitudinal variation in body length of *C. polita*, with individuals from more northern populations being generally larger than in southern populations. However, environmental conditions, such as the type of substrate or depth of water, may also strongly affect body size (Burbanck and Burbanck 1979). To assess whether cyathurans from Saint John followed this latitudinal trend, their mean body lengths were compared to values reported in the literature (Table 2). Females pooled from all stations had a mean length of 13.8 ± 2.14 mm (maximum: 20.0 mm), and males had a mean length of 16.3 ± 2.41 mm (maximum: 24.0 mm). These lengths were similar to cyathurans populations studied north of North Carolina, although none collected at Saint John were as large as the maximum length (27 mm) of the individuals collected from Chewonki Creek, Maine (Burbanck 1959). The individuals collected in the Saint John estuary differed markedly from southern populations such as Georgia and Florida: the largest male collected at St. Mark's, Florida, was only 1.8 mm larger than the smallest male collected in the Saint John (Kruczynski and Subrahmanyam 1978).

Broods were examined from 72 females, pooled from all four stations. Fecundity ranged from 16 to 98 embryos per brood, with a mean of 53.2 ± 18.9 embryos (Table 3). Abundant gravid females with embryos were first observed on 1 July. All of these broods contained early embryos (Class 1), with a mean length of 0.45 ± 0.06 mm. Two weeks later, more than half of the broods contained elongated Class 2 and 3 embryos, while the remainder contained Class 1 embryos. By the end of July, 50% of broods contained Class 4 young that had hatched out of their vitelline membranes but were still developing within the marsupia. By mid-August, only six gravid females were found: two had very large Class 1 broods and two had late-stage Class 4 broods. Within the marsupium, embryos grew from a mean length of 0.49 ± 0.08 mm as Class 1 embryos to a mean length of 2.07 ± 0.16 mm when they were ready to be released as juveniles. Class 2 and 3 embryos had a mean length of 1.05 ± 0.15 mm and 1.12 ± 0.19 mm, respectively (Table 3).

There was no correlation between female length and fecundity ($R^2 = 0.01$). There was also no effect of embryos/brood on embryo size ($R^2 = 0.01$) and little mortality within broods during development (Mercer 2005). Within-brood survivorship was 96.4% with only a slight decrease observed in mean embryos/brood when compared between Class 1 (57.9 ± 18.77 embryos/brood) and Class 4 broods (55.8 ± 19.64 embryos/brood).

Discussion

Cyathura polita from the Saint John River estuary exhibits several modifications in life history associated with its northern distribution. In particular, this population exhibits a longer life span, a shorter and later reproductive season, and produces larger adults with higher fecundity, in comparison to southern populations. Additionally, our data suggest that protogynic hermaphroditism occurs, as found in some other populations (Burbanck and Burbanck 1974).

In the Saint John River estuary, *C. polita* exhibits a three-year life cycle. Juveniles are released during July and August (Age 0) and, after little growth during the winter, remain immature the following summer (Age 1). Over the course of their second winter, juveniles develop into mature females (Age 2), which reproduce the following summer. Then, based on our length and sex ratio data, females either die or become males (Age 3) during the late summer-fall, and reproduce as males during their final summer of life. The result is a three-year life cycle, which spans four summers. In contrast, *C. polita* from southern populations have shorter life cycles. For example, in St. Mark's, Florida, *C. polita* are mature one year after hatching and reproduce throughout their second summer, suggesting a life cycle of less than two years (Kruczynski and Subrahmanyam 1978), while on southern Cape Cod, *C. polita* reproduce in their second, and sometimes third, summer, suggesting a two-year life cycle (Burbanck 1962a; Burbanck and Burbanck 1979).

Latitudinal changes in the duration and timing of reproduction are also evident. *Cyathura polita* reproduce from April to August in St. Mark's, Florida (Kruczynski and Subrahmanyam 1978), from June to July at Cape Cod, Massachusetts (Burbanck 1962a) and July and August in the Saint John estuary (present study). Although the breeding season is short and relatively simultaneous in the Saint John population, females were found with broods at different stages of embryonic development throughout the brooding period, especially in mid- to late-July.

The longer life cycle and delayed reproduction in northern cyathurans probably occur because of a shorter growing season. The population in the Saint John lives in water that averages 19.0°C during summer, but shallow water temperatures decline to near 0°C from December until April (Metcalfe et al. 1976). The result is limited opportunity for growth and reproduction in warmer waters, resulting in delayed maturation. In contrast, cyathurans from Florida live at temperatures ranging between 13.8° and 33°C, and above 20°C for ten months of the year (Kruczynski and Subrahmanyam 1978). Previous studies suggest that rapid growth in cyathurans occurs only during periods

TABLE 2. Summary of body lengths for *C. polita* reported in the literature, as means ± S.D. or range, depending on the source.

Location of study	Body length (mm)	Author(s)

TABLE 3. Fecundity and mean embryo length of *Cyathura polita* in the Saint John River estuary. Embryos were grouped by class of development where: Class 1 embryos were round and contained in two membranes, the chorion and vitelline. Class 2 embryos were elongated and differentiated into three body regions (head, thorax and abdomen). Class 3 embryos were within vitelline membrane but had differentiated appendages. Class 4 embryos were hatched from the vitelline membrane (Mercer et al. *in press*).

Date collected	Class of development	Number of gravid females	Fecundity Mean ± SD	Total number of embryos	Embryo length (mm) Mean ± SD
1 July	1	15	52.8 ± 22.48	956	0.45 ± 0.06
17 July	1	13	59.4 ± 11.08	658	0.52 ± 0.09

	4	2	33.5 ± 41.72	67	2.15 ± 0.18

of higher water temperature, and that growth ceases when waters cool (Olafsson and Persson 1986). The two-year life cycle described for Cape Cod may be more similar to the southern populations, perhaps because the southern side of Cape Cod, where the study was conducted, is more Virginian in nature than Boreal (Gosner 1971).

Cyathura carinata, common along the coast of Europe, exhibits a similar cline in life history traits. Studies of *C. carinata* in Portugal have suggested relatively short life cycles of 19 (Cruz et al. 2003) or 18 to 22 months (Marques et al. 1994). However, three-year life cycles are reported for *C. carinata* populations in more northern locations such as Poland (Jazdzewski 1969), Sweden (Olafsson and Persson 1986) and England (Bamber 1985). Olafsson and Persson (1986) suggest that *C. carinata* populations in Sweden require two years before juveniles are able to mature and reproduce, in contrast to southern populations, which are able to reproduce after one year. Bamber (1985) suggests that a longer life cycle is necessary in northern populations as the isopods cannot grow during the winter; whereas southern populations are able to grow continuously and attain mature size sooner.

Cyathura polita in the Saint John River estuary appears to exhibit protogynic hermaphroditism. Sequential hermaphroditism is rare in marine peracaridans, although relatively common in terrestrial and parasitic species (Johnson et al. 2001). Brooks et al. (1994) report that of the approximately 60 species of crustaceans known to be sequential hermaphrodites, only a few are protogynous, including three species of *Cyathura*, three other isopods and five species of tanaids. Evidence for protogyny from the present study includes sex ratio and adult size. Males were abundant in the population in May and again in October, but rare during summer when the majority of adults were females. Also, males in the fall were similar in length to spent females at the end of the summer (approximately 15 and 12 mm in length, respectively), while most large juveniles were smaller (approximately 10 mm in length). Males continue to grow during the fall and reach a length of approximately 18 mm in the spring of their final year. These observations support a model of protogynic hermaphroditism, whereby mature females become reproductive in early summer of their second year (i.e., third summer) and release juveniles during late July and August. After the release of young,

females molt, change sex, and function as mature males in their fourth spring and summer, before death.

The hypothesis that *C. polita* in the Saint John River are protogynic hermaphrodites is consistent with evidence of sex change reported from other populations under both laboratory (Burbanck and Burbanck 1974) and field conditions (Kruczynski and Subrahmanyam 1978). While it is possible that males migrate to other areas of the estuary after reproducing and return to shallow waters in the fall, previous work suggests that mostly immature cyathurans occur in the deeper waters of this estuary, while reproductive adults are in shallower water (Gillis 1974; Burbanck et al. 1979). Burbanck and Burbanck (1974, 1979) have reported that some primary males can develop directly from juveniles, which may account for some of the variation in sex ratios and body lengths observed here.

As hypothesized by Bamber (1985), it would be advantageous for male cyathurans to be larger than females to reduce their chances of mortality. Males are able to mate with more than one female, but need to leave their burrows in order to mate, thus they are at a greater risk of predation. Females do not need to expose themselves to that risk, and thus may mature at a smaller size. Warner (1988) additionally suggested that it would be advantageous to become male at a larger size if there is competition among males for females.

With a few exceptions, the development of embryos collected at Saint John was synchronized within a brood, which agrees with observations on cyathurans by Stromberg (1972) and Bamber (1985). Our observations suggest that the brooding period for females in the Saint John River estuary lasts from 30 to 45 days. Class 1 embryos were first observed in marsupia on 1 July. The first hatched embryos (Class 4) were observed on 31 July, which corresponds with the first appearance of new juveniles. While comparable observations are not available for more southern populations of this species, a 30 to 45 day brooding period may be typical for this genus. Olafsson and Persson (1986) found that a *C. carinata* population on the southern coast of Sweden had a three to four week brooding period, while others studying *C. carinata* in Portugal determined embryonic development to also last 30 to 45 days (Cruz et al. 2003).

Brood size is not widely reported for *C. polita*, however broods collected from Saint John were much larger (53.2 ± 18.9 embryos/brood) than broods from Florida (mean: 14 embryos/ brood, range 2-32; Kruczynski and Subrahmanyam 1978). A similar south-north cline is known in the European *C. carinata*. Bamber (1985) found that *C. carinata* females in England carry a mean of 29.8 embryos/brood (range 14-45), while *C. carinata* females in Sweden averaged 42 ± 12 embryos/brood (Olafsson and Persson 1986). The large brood size in Saint John *C. polita* is likely a function of increased female size because of greater age (3 vs. 2 years). Larger females would likely have larger marsupia and therefore may be able to carry more embryos.

Cyathura polita at the northernmost extent of its range exhibits several modifications in life history compared to more southern North American populations. These modifications are similar to those observed among European *C. carinata* populations. Our results support the existence of a latitudinal cline in life history traits in *Cyathura*, with implications for life span, size and fecundity. Plasticity in reproduction, coupled with protogynic hermaphroditism, makes *C. polita* an excellent model for studies of the effects of the environment on life history traits.

Cyathura polita is an important indicator of estuarine health (Burbanck and Burbanck 1979) and since the Saint John River estuary has one of the few populations in Canada there are compelling reasons to understand its life history and population size. We suggest a more comprehensive knowledge of the biology of this isopod in the Saint John could assist both with pollution monitoring and with further the distinction of the Saint John estuary as a distinct ecosystem in Canada. Future study of the Saint John cyathurans should be undertaken to verify the 3-year life cycle with sampling throughout the year and to define its estuarine distribution and abundance. *Cyathura polita* occurs as far inland in the Saint John estuary as Washademoak Lake (Figure 1; Burbanck et al. 1979) and it is a common prey of the Shortnose Sturgeon (*Acipenser brevirostrum*) another southern species that is endemic to this estuary in Canada (Dadswell 1979).

Ultsch, Gordon R., Matt Draud, and Barry Wicklow. 2007. Post-emergence movements and overwintering of Snapping Turtle, *Chelydra serpentina*, hatchlings in New York and New Hampshire. Canadian Field-Naturalist 121(2): 178–181.

Hatchling Common Snapping Turtles (*Chelydra serpentina*) were captured within, or as they emerged from, their nest cavities in Long Island, New York, and in southeastern New Hampshire. They were fitted with radiotransmitters and released at their nest sites. Their movements were monitored for as long as possible, which for some included tracking them to their overwintering sites and relocating them the following spring. On Long Island, all hatchlings initially moved to water. Later movements were both aquatic and terrestrial, and those that could be located while overwintering had left the water and hibernated in spring seeps, where they were recovered alive the following April. In New Hampshire, hatchlings moved directly to nearby aquatic habitats after emergence, where they spent the winter submerged in shallow water in root masses near banks.

Key Words: Common Snapping Turtle, *Chelydra serpentina*, hatchling turtles, hibernation in turtles, New York, New Hampshire.

In northern climates, the behavior of hatchling aquatic turtles, once they have pipped and left the eggshell, is variable both among and within species. In some species the majority of hatchlings remain in the nest until the following spring, although some fall emergence may occur. These include Painted Turtles (*Chrysemys picta* – Zwiefel 1989; Lindeman 1991; Pappas et al. 2000), Common Map Turtles (*Graptemys geographica* – Pappas et al. 2000; Baker et al. 2003; Nagle et al. 2004), and Diamondback Terrapins (*Malaclemys terrapin*; Baker et al. 2006). For the two former species, it is assumed that if the hatchlings leave the nest, they overwinter aquatically, while for the latter species fall emergence coupled with aquatic or terrestrial overwintering has been reported (Draud et al. 2004), as well as overwintering in the nest coupled with fall emergence (Baker et al. 2006). Other species have been consistently reported to be overwhelmingly fall emergers, including Snapping Turtles (*Chelydra serpentina* – Obbard and Brooks 1981; Carroll and Ultsch 2007), Spiny Softshell Turtles (*Apalone spinifera* – Christiansen and Gallaway 1984; Costanzo et al. 1995), Musk Turtles (*Sternotherus odoratus* – Cagle 1942; Mitchell 1988), Wood Turtles (*Glyptemys insculpta* – Harding 1991; Carroll and Ultsch 2007), Spotted Turtles (*Clemmys guttata* – Ernst 1976; Carroll and Ultsch 2007), and Blanding's Turtles (*Emydoidea blandingii* – Standing et al. 1997, 1999; Pappas et al. 2000). Hatchlings of most of these species are assumed to overwinter aquatically, even though some may remain on land for extended periods before entering the water; e.g., Wood Turtles (Tuttle and Carroll 2005; Castellano, Behler, and Ultsch, unpublished data) and Blanding's Turtles (Standing et al. 1997, 1999). However, there are some reports of suspected terrestrial overwintering in the hatchlings of some of these species, based largely on the capture of one or a few individuals in spring in microhabitats that are suggestive of non-aquatic overwintering (Ernst 1966, 1976; Standing et al. 1997; Pappas et al. 2000, Parren and Rice 2004). While such behavior does not appear common, its degree of occurrence is uncertain.

There are no reports of following individual hatchlings from the time of emergence from the nest until the resumption of activity the next spring. The typical approach of a study of overwintering behavior, a number of which have been done with adult turtles (reviewed by Ultsch 2006), has been the use of radiotelemetry, permitting tracking of the turtles throughout the hibernation period, including entrance and exit. Recently, transmitters small enough to attach to hatchlings have become available, which allows tracking of the animals from the nest to their wintering grounds, although battery life is not yet long enough to track the turtles until the following spring. However, once the turtles go into hibernation, they move little, which potentially allows recovery during the early spring before movement is resumed.

Here we report on the post-emergence and overwintering behavior of Snapping Turtle (*Chelydra serpentina*) hatchlings in Long Island, New York, and in southeastern New Hampshire. In both localities the hatchlings moved to water rather directly, but their eventual overwintering sites differed considerably at the two locations.

Methods

On Long Island, 15 Snapping Turtle hatchlings were collected in the nest on 11 September 2004 from two nest sites (seven from one and eight from the other) in the vicinity of Cold Spring Harbor, Nassau County. The nests were located along an earthen dam separating a lake from the stream formed by the dam overflow. They were brought to the laboratory, fitted with 0.9 g BD-2 transmitters (Holohil Systems Ltd., Carp, Ontario, Canada) attached to the carapace with cyanoacrylate glue (Krazy Glue®), and released into their respective nest cavities on 13 September 2004. All hatchlings left the nest cavity within 10 min. Telemetry commenced on 14 September, using a Communication Specialists model R1000 receiver. The expected life of the transmitters was 30 days, and some were replaced on day 30. Whenever possible, a visual location was paired with the telemetric location, which was recorded with a hand-held Magellan GPS 315. Hatchlings were located on nine days from 14-30 September, 10 days from 2-28 October, and on 5 and 12 November. Five hatchlings were lost during the study. Hatchlings that entered final hibernation sites were marked by surveyor flags for recovery, which occurred on 5 April 2005.

In New Hampshire, hatchlings were collected from both riverine and palustrine habitats. Six hatchlings were collected from a nest site 20 m from a third-order stream (riverine site) and 18 hatchlings were collected from two adjacent nests 3 m from a first-order stream (palustrine site) within a wetland complex. On 17 September 2005 six hatchlings from the riverine site were brought to the laboratory and fitted with 0.5 g A2415 transmitters (Advanced Telemetry Systems [ATS], Inc., Isanti, Minnesota) attached to the carapace with epoxy resin. They were released at the nest site on 19 September 2005. Hatchlings were located using an ATS FM-100 receiver and their GPS coordinates recorded using a Trimble Geoexplorer 3. At the palustrine site, nine hatchlings emerging from a nest (22 September 2005) were fitted on site with Holohil transmitters (see above) attached to the carapace using epoxy resin. These hatchlings were then returned to the nest. After a flash flood event during the first week of October 2004, 12 hatchlings were lost. At that time transmitters were attached on site to eight additional hatchlings captured at the site in shallow water. Hibernation sites were marked using surveyor flags. These sites were searched in March 2006.

Results

On Long Island, 10 hatchlings were followed. The transmitter became detached from three after their movement to water. Two others were found dead. One moved to the water and was found dead on a beach after 26 days. One exhibited considerable movement activity (34-260 m between location periods), including some terrestrial movements, and by 5 October had moved to a seep, buried in leaves near the surface; it was found dead there on 3 April at a depth of 5 cm. One moved into and out of water and then back into the water, and was located on 12 November dug into sand under a tree root in about 8 cm of water. This animal could not be located the following April.

Four hatchlings were tracked to their hibernation quarters and located the following spring. One moved immediately to water, then was found on 2 October under a log 8 m from water. By 10 October it had moved uphill to a spring seep, and two days later had dug to about 20 cm depth and did not move through 12 November. It was found alive and responsive at the same site on the following 3 April in 8 cm of saturated mud. A second moved directly to water and then emerged onto land on 30 September about 1.5 m from the water. By 2 October it had moved to a site about 20 m from the water, where it buried under leaves and remained until 8 October. By 10 October it had moved 15 m and was at the surface under cat briar. On 12 October it had moved to a second spring seep, where it buried, moved, and reburied over a 6-day period to depths of 10-13 cm. By 21 October it had relocated in the seep and buried to about 15 cm and had not moved by the last observation on 12 November. It was found alive and alert near the surface at the same location on 3 April. A third moved to water, and moved aquatically until 30 September, when it moved into the same seep area as the second, where it moved intermittently, being found buried at depths of 8-13 cm until 18 October, when it settled into the wet organic detritus along the side of a fallen tree, and had not moved by 12 November. It overwintered there and was found alive and well at the surface of the mud at the same site on 3 April. A fourth moved to and about in shallow water for five days. By the seventh day it had left the water and buried into moist sphagnum moss about 0.25 m from shore for 3-5 days without moving. It then moved back to water for 2-3 days and then back onto land on 30 September, where it buried for three weeks about 8 cm into the same seep used by the second and third hatchlings. It then moved downward to about 15 cm by 21 October and did not move through 12 November. It was recovered alive at this site on 3 April.

In New Hampshire, at the riverine site, 5 of 6 hatchlings moved first up a gentle slope and then down a steep slope to the river 6 m below. Three of these entered the river within 3 h of release, one after 24 h, and one after 36 h. The sixth moved 8 m on land, down a slope, and burrowed under leaves and then entered the water the next day, all within 24 h of release. The hatchlings remained within 20 m of their entrance points into the river, remaining in shallow (2-3 cm) water, and often buried in sand or detritus with only the head exposed. After extreme flooding caused by heavy rains (25-30 cm in 3 days) in early October, the hatchlings were lost. Three detached transmitters were

found, suggesting significant buffeting of the hatchlings.

At the palustrine New Hampshire site, 15 hatchlings (five with and 10 without transmitters) traveled 3-5 m to enter a nearby wetland stream within 4 h of release. Of the four additional hatchlings with transmitters, one burrowed back into the sand of the nest, where it remained for 2 days until dug out by a predator. Two more entered the water within 24 h, and the fourth traveled 5 m, remained under wetland vegetation for one day, burrowed into sand one day, then traveled 20 m to shallow water (8 cm) at the edge of the stream. Six hatchlings were lost after a flood during the first week of October. On 11 October 2005, eight additional hatchlings were located along the stream within 5 m of the nest. Each was fitted with a transmitter on site and then returned to the stream. Of these, one moved 15 m downstream into the flooded wetland within 24 h, two moved 12 and 17 m downstream into the wetland by 16 October 2005. A fourth moved 15 m into the wetland by 2 November 2005. Four hatchlings remained tucked into roots of sedges and silky dogwood in 2-3 cm water along the edge of the wetland stream, 3-5 m from the nest. A fifth had remained in this location since 22 September 2004 (visually located on 2 November 2005). Three hatchlings were relocated in March 2006, and they were all at the locations at which they were last observed in November 2005. One was located on 8 March, 6 cm below the surface and 2.5 m from the nest site, under sedge roots at the edge of the stream in 1°C water. A second was found on 8 March, 6 cm below the surface in 1°C water under leaves at the base of a submerged log in the wetland 15 m from its nest. A third was found on 10 March, 7 cm below the surface in 2°C water under silky dogwood roots at the edge of the stream 2.5 m from its nest. The three hatchlings increased in mass by 12.9 to 19.5% from autumn release to spring capture, but we cannot partition mass gain between possible autumn feeding and potential winter water uptake.

Discussion

Although the transmitters were small, they still were up to ≈10% of the body mass of the hatchlings, and potentially could snag on vegetation during locomotion. While we cannot discount effects on behavior, since the hatchlings within a given group behaved similarly, we do not think that transmitter attachment had a major effect on behavior relative to that of an unfettered hatchling.

On Long Island, the four hatchlings that were recovered from their hibernacula in April all overwintered in spring seeps away from standing water, in contrast to the behavior of the New Hampshire hatchlings, which all moved to shallow water and remained there to overwinter. The four Long Island hatchlings also initially moved to open water from their release in the nest cavity (two from each nest), but they then followed different paths, sometimes including both aquatic and terrestrial movements, before eventually settling into the spring seeps for overwintering, as did the fifth, although we could not find it in April. In the sense that Long Island hibernacula were not under standing water, the hibernacula were terrestrial and differed from those expected by assuming that hatchlings move to aquatic lentic or lotic habitats and overwinter there, as was the case with the New Hampshire hatchlings. However, the Long Island hatchlings were surrounded by a constantly saturated medium that appeared to have an underground flow, so desiccation was not a threat. We do not know the oxygen content of the interstitial water, but assume that it was appreciable or the turtles would have died if they had remained submerged throughout the winter. Reese et al. (2004) found that Snapping Turtle hatchlings will die in 30 days if submerged in anoxic water at 3°C, compared to survival of adults for at least 125 days under similar conditions (Reese at al. 2002). The limited survival of anoxic hatchlings is attributable to their reduced whole-body buffering capacity, and therefore reduced tolerance of the metabolic acidosis that accompanies the accumulation of lactic acid during anaerobiosis. The reduced buffering capacity is due to the reduced relative amount of bone, especially in the shell, of the hatchlings compared to adults, and is a general characteristic of hatchling turtles (Reese et al. 2004). This inability to tolerate anoxia would preclude the turtles from hibernating for extended periods in anoxic conditions, such as mud under standing water. Thus the seep water that surrounded the hatchlings must have had a significant amount of dissolved oxygen, perhaps maintained by a constant percolation of oxygenated spring water that exceeded the biochemical oxygen demand of the detritus at the low wintertime temperatures. Alternatively, it is possible that the hatchlings may have occasionally air-breathed, since the soil surface of the seeps did not freeze during the winter. Air-breathing would require that the animals move to the surface to breathe (on the assumption that the water saturation prevents any underground air pockets from forming); since turtles are not completely immobilized by cold, air-breathing cannot be ruled out. Why the hatchlings moved out of open water to hibernate in the seeps, or how they oriented toward them, is uncertain.

Thus the overwintering habitats of hatchling Snapping Turtles are varied, ranging from the expected shallow-water retreats typical of the New Hampshire hatchlings, to the use of wet but not aquatic sites (e.g., seeps), even though aquatic sites are nearby and easily accessible, as seen with the Long Island hatchlings. The use of seeps as hibernacula for turtles, especially young ones, may be more common than has been appreciated. V. Lamoureaux (personal communication), while studying the use of seeps as hibernacula for Green Frogs (*Rana clamitans*) in New York (Lamoureux and Madison 1999), found one adult and three

juvenile (9.5 – 11 cm) Snapping Turtles leaving a seep area in late April, where they apparently overwintered, and moving toward a nearby pond. Dunson (1986) radiotracked four snapping turtles in a tidal marsh area in Virginia, and they all moved to seep/spring areas on higher ground, which remained unfrozen throughout the winter, suggesting that the use of seeps as hibernacula may not be limited to immature turtles, although almost all reports of hibernacula of adult Snapping Turtles are of those covered by standing or flowing water (Ultsch 2006).

Acknowledgments

We thank Sara Zimnavoda for help with radiotracking in Long Island and students of the Aquatic Ecology course at St. Anselm College for similar aid in New Hampshire. This study was supported by a National Science Foundation grant to GRU (IBN 0076592).

Notes on Succession in Old Fields in Southeastern Ontario: the Herbs

A. Crowder[1,3], R. Harmsen[1], and S. E. Blatt[2]

[1]Department of Biology, Queen's University, Kingston, Ontario K7L 3N6 Canada

Crowder, A., R. Harmsen, and S. E. Blatt. 2007. Notes on succession in old fields in southeastern Ontario: the herbs. Canadian Field-Naturalist 121(2): 182-190.

Vegetation in abandoned hayfields was monitored during 1976-1998. An earlier successional stage followed ploughing. Changes in tree, shrub and vine populations have been reported earlier and showed expected increases in species richness and cover. Highest species richness of herbs occurred three years after ploughing. Non-woody species richness trended irregularly downward, while non-woody cover was variable, peaking in 1987. Within the herbaceous community, year-to-year changes in cover and frequency of species in the following selected groups are reported here: 18 grasses including sown and adventive species; 13 legumes including two sown species; 14 macroforbs of the *Compositae*, including a goldenrod, *Solidago canadensis,* which dominated parts of the fields; a rosette weed, *Taraxacum officinalis*; sedges, horsetails and some other minor components. Grasses and goldenrods were grazed, sometimes intensively and repeatedly, by insects; grasses were impacted by skipper larvae (*Thymelicus lineola*), and goldenrods by beetle larvae (*Trirhabda* spp.). Effects of repeated outbreaks on host plant cover are shown for two plots (100 m^2) matching the scale of outbreaks.

Key Words: old field herbs, phytophagous insects, plant succession, goldenrods, grasses, legumes, Ontario.

Two abandoned hayfields in southeastern Ontario were selected as sites in which to investigate possible effects of insect herbivory on early stages of secondary succession. The location, geology, history of land use, and soils have been described earlier (Crowder and Harmsen 1998). Their nutrient status was discussed by Epp and Aarssen (1988). Estimates of increasing cover and abundance of trees, shrubs and vines (51 species) during 1976-1998 were shown to follow classic successional models, although with unusual pioneer species. After two decades the structure of the vegetation had become heterogeneous, with groves of small trees, shrub thickets, patches dominated by macroforbs and patches still dominated by grasses. Cover varied with fluctuations of weather from year to year, while soil differences influenced cover and species richness.

Most successional studies on old fields use synoptic records from fields of different ages, a method which obscures minor fluctuations and differences between fields. In this paper, year-to-year observations are used to follow temporal changes in the herbaceous community and to relate its cover and species richness to those of the woody layers. Herbaceous species found in 27 experimental plots are listed to allow comparisons with other areas; lichens and bryophytes are omitted. Differences in soil texture (Crowder and Harmsen 1998) influenced cover and richness.

Within the herbaceous community, details of temporal change in selected groups of plants and some specific interactions are reported here. Grasses were the main constituents of the hayfields, including both agricultural and adventives species. Legumes also included sown and invasive species. Invasive macroforbs, mainly *Solidago* and *Aster* species, dominated parts of the fields; population changes of 15 species are reported. *Taraxacum officinalis*, Dandelion, was selected to represent rosette plants. Sedges, horsetails and a few other minor components are described.

During the decades when vegetation was monitored, arthropods were also sampled (McBrien et al. 1983). Two insect populations had repetitive outbreaks which caused significant decreases of plant cover, and are therefore the only arthropods reported here. Larvae of the hesperiid European Skipper (*Thymelicus lineola*) grazed on grasses, particularly on Timothy, *Phleum pratense* (Henderson 1986). Larvae of beetles of the genus *Trirhabda* Le Conte (Coleoptera, Chrysomelidae), mostly *Trirhabda virgata,* grazed primarily on leaves of *Solidago canadensis*, causing intense defoliation. The strong effect of one or more outbreaks of beetles on plant vigour was replicated experimentally (McBrien and Harmsen 1987). These defoliations can cause changes in successional pathways at the grass-macroforb stage by affecting the relative dominance of grass or goldenrods. Blatt et al. (2001) have used these data to develop a successional model including herbivore effects, showing possible outcomes for the herbs.

Methods

A hayfield abandoned in 1970 and one mown for hay until 1975 were selected at Queen's University Biology Station at Opinicon, Frontenac County, Ontario (44°03'N, 76°0'W). Nine permanent plots, each 100 m^2, were demarcated in 1975 in the older field, which was called S field, for *Solidago*. Eighteen similar

plots were placed in the younger field, and nine of these were ploughed once; these ploughed plots were called P and the undisturbed plots G, for grass. All plant species present in the 27 plots were listed in June and September of sampling years: 1976-1988, 1995, 1998. Cover was estimated using five randomly placed quadrats within each plot; cover values used in this paper were from September (McBrien et al. 1983; Henderson 1986). Each quadrat was 50 cm × 50 cm in area. Values were compared using Scheffe's mean separation test (Zar 1984; Blatt et al. 2003). Percentage frequency, the number of quadrats in which a species was recorded at a particular time (Mellinger 1972; Eriksson and Jakobssen 1998), was used as a measure of relative abundance (Maycock and Guzikowa 1984).

Nomenclature follows Newmaster et al. (1998); voucher specimens were lodged at the Fowler Herbarium, Queen's University. Lichens, mosses and liverworts have been omitted from this paper.

Results and Discussion

Species richness of woody species and of herbs per 100 m^2 plot, through 1976-1998, is shown in Figure 1. Note gaps in sampling after 1988. Herb richness trended downward with high annual variance while woody species richness increased over time (see Crowder and Harmsen 1998).

The range of species richness was 7-65 in ploughed (P) plots, 6-42 in grass-dominated (G) plots, and 6-33 in *Solidago* (S) plots. Species richness of herbs and of woody plants in a grass plot (G1) and a ploughed plot (P2) are shown in Figures 2 and 3. Because soil texture was found to be correlated with species richness, the selected plots were matched for texture; both are sandy, with relatively low richness (Crowder and Harmsen 1998). Note the difference in scale between Figures 2B and 3B. Species richness peaked in P2 three years after ploughing when several weedy species were present (cf. Armesto and Pickett 1985).

Herbaceous taxa observed in 27 plots during 1976-1998 are listed in Table 1, in alphabetical order, with English names added (Newmaster et al. 1998). The closest comparable study site is a 50-year-old field, at Erindale (Toronto area), described by Maycock and Guzikowa (1984), in which 93% of the species listed at Opinicon were found. Other old fields in Ontario have been described by Lamoureux (1970), Reader (1990) and Reader and Buck (1991). Fewer of the Opinicon species (37%) were found in abandoned hayfields in New York State described by Mellinger (1972), and only 20% in old fields in Quebec (Dansereau and Gille 1949). The proportion of introduced species at Opinicon was 37%, which is higher than the average for the Kingston region (Beschel et al. 1970). They included both crop plants and weeds.

During 1976-1998 the cover value of woody plants for all plots combined increased significantly (Crowder and Harmsen 1998); herbaceous cover, however, did not decrease significantly over time (Figure 1). Mean percent cover of non-woody species in 1998 was not significantly different from that in 1988, 1986, 1984, 1978, 1977 and 1976. Years with high cover were 1979, 1980, 1981, 1985, or 1987 (Figure 1). These values suggest that herbaceous cover was related to year-to-year changes in weather or herbivory rather than to a steady increase in shading. No correlations of cover values with available climatic data were found, although the years with low cover had partial droughts that caused soil cracking.

Herb cover in selected plots is shown in Figures 2A and 3A, with relatively low variance between years. Plot G1 consistently had higher values than P2. The main components of herb cover are discussed in the following section. The hayfields had been sown with *Phleum pratense* (Timothy) and *Poa pratensis* (Kentucky Blue Grass), which maintained their frequency after the cessation of mowing (see Table 2). Mellinger (1972) also reported their high frequency in old hayfields in New York. In the Opinicon fields the two species are associated randomly (Epp and Aarssen 1988).

Table 2 lists annual percentage frequency of nine grass species. The most frequent invasive grasses have been *Elymus repens*, *Poa compressa* and *Calamagrostis canadensis*. Other less common invasive grasses, not shown on Table 2, were *Bromus inermis* ssp. *pumpellianus*, *Echinochloa crusgalli*, *Elymus trachycaulon* ssp. *trachycaulon*, *Muhlenbergia mexicana*, *Panicum acuminatum*, *Poa capillare*, *Poa annua*, *Setaria pumila* and *Setaria viridis*. Annual cover of all grass species in all plots varied from a mean of 35% in 1998 to a mean of 87% in 1987. Cover in the G (grass) plots exceeded 100% in some years, because layers of two or more species developed. Differences between the three sets of plots were not consistent.

Cover of grasses did not show synchronous trends within sets of plots. Changes in grass cover were not correlated with soil texture; the two plots shown in Figures 2 and 3 were matched for soil texture but the undisturbed plot G1 in Figure 2 had high grass cover and the ploughed plot in Figure 3 had not. A temporal pattern in the grass-dominated plot showed successive peaks three to five years apart followed by declines in cover values. This pattern was typical of grass-dominated plots. The disturbed ploughed plot shown in Figure 3 had two less marked peaks and declines. Herbivory was demonstrated by Henderson (1986) to reduce grass cover significantly; he counted larvae of a hesperiid European Skipper (*Thymelicus lineola*) and found that peaks of larval numbers coincided with low cover of *Elymus repens*, *Phleum pratense* and *Poa pratensis*, and low concentrations of skipper larvae with high grass cover. The grass species differed in their capacity to recover after an insect outbreak, with *Phleum pratense* being most negatively affected. Outbreak behaviour by the European Skipper has been documented by Pengelly (1961) elsewhere in Ontario.

TABLE 1. Alphabetic list of herbs recorded within 27 plots during 1975-1998 at two old fields at Opinicon, with English names. Nomenclature follows Newmaster et al. (1998).

Acalypha virginica. Copperleaf
Achillea millefolium ssp. *millefolium.* Yarrow
Agrimonia gryposepala. Hooked Agrimony
Agrostis gigantea. Redtop
Ambrosia artemisiifolia. Common Ragweed
Anaphalis margaritacea. Pearly Everlasting
Anemone canadensis. Canada Anemone
Antennaria neglecta. Field Pussytoes
Antennaria parlinii. Plantain-leaved Pussytoes
Arctium minus ssp. *minus.* Common Burdock
Artemisia absinthium. Absinth
Asclepias syriaca. Common Milkweed
Aster cordifolius. Heart-leaved Aster
Aster ericoides. Heath Aster
Aster lanceolatus. Panicled Aster (includes *Aster simplex*)
Aster lateriflorus. Calico Aster
Aster umbellatus. Flat-topped White Aster
Aster urophyllus. Arrow-leaved Aster
Barbarea vulgaris. Wintercress
Bromus inermis ssp. *pumpellianus.* Smooth Brome
Calamagrostis canadensis. Canada Blue Joint
Capsella bursa-pastoris. Shepherd's Purse
Carex aurea. Sedge
Carex communis. Common Sedge
Carex debilis. Sedge
Carex foenea. Sedge
Carex gracillima. Filiform Sedge
Carex granularis. Granular Sedge
Carex laxiflora. Slender Sedge
Carex normalis. Normal Sedge
Carex scoparia. Sedge
Carex vulpinoidea. Fox Sedge
Cerastium fontanum ssp. *triviale.* Common Mouse-ear Chickweed
Chenopodium simplex. Maple-leaved Goosefoot
Chrysanthemum leucanthemum. Ox-eye Daisy
Cichorium intybus. Chicory
Cirsium arvense. Canada Thistle
Clinopodium vulgare. Wild Basil
Convolvulus arvensis. Field Bindweed
Conyza canadensis. Canada Fleabane
Dactylis glomerata. Orchard Grass
Danthonia spicata. Poverty Oat Grass
Daucus carota. Wild Carrot
Dianthus armeria. Deptford Pink
Echinochloa crusgalli. Echinochloa
Echium vulgare. Blueweed
Elymus repens. Couchgrass
Elymus trachycaulus ssp. *trachycaulus.* Slender Wheat Grass
Epilobium hirsutum. Hairy Willow Herb
Equisetum arvense. Field Horsetail
Equisetum hyemale. Scouring Rush
Erigeron annuus. Daisy Fleabane
Erigeron philadelphicus ssp. *philadelphicus.* Common Fleabane
Erigeron strigosus. Lesser Fleabane
Eupatorium maculatum. Joe Pye Weed
Eupatorium perfoliatum. Boneset
Eupatorium rugosum. White Snakeroot
Euthamia graminifolia. Grass-leaved Goldenrod
Fragaria vesca ssp. *americana.* Wood Strawberry
Fragaria virginiana. Wild Strawberry
Galinsoga quadriradiata. Quickweed
Galium obtusum. Wild Madder
Galium trifidum ssp. *trifidum.* Small Bedstraw
Gentiana andrewsii. Bottle Gentian
Geranium bicknellii. Bicknell's Crane's Bill
Geum aleppicum. Yellow Avens
Geum canadense. White Avens
Hieracium aurantiacum. Orange Hawkweed
Hieracium piloselloides. King Devil
Hypericum perforatum. Common St. John's Wort
Juncus dudleyi. Dudley's Rush
Lactuca canadensis. Wild Lettuce
Lepidium campestre. Field Peppergrass
Lithospermum officinale. Gromwell
Lobelia inflata. Indian Tobacco
Lycopus americanus. Cut-leaved Water Horehound
Lycopus uniflorus. Water Horehound
Lysimachia terrestris. Yellow Loosestrife
Medicago lupulina. Black Medick
Medicago sativa ssp. *sativa.* Alfalfa
Medicago sativa ssp. *falcata.* Medick
Melilotus alba. White Sweet Clover
Melilotus officinalis. Yellow Sweet Clover
Mentha arvensis ssp. *borealis.* Wild Mint
Muhlenbergia mexicana. Dropseed
Oenothera perennis. Sundrops
Onoclea sensibilis. Sensitive Fern
Osmunda regalis. Royal Fern
Oxalis stricta. Yellow Wood Sorrel
Panicum acuminatum. Woolly Panic Grass
Panicum capillare. Witch Grass
Panicum depauperatum. Starved Panic Grass
Phleum pratense. Timothy
Physalis heterophylla. Clammy Ground Cherry
Plantago lanceolata. Narrow-leaved Plantain
Plantago major. Common Plantain
Plantago rugelii. Rugel's Plantain
Poa annua. Annual Blue Grass
Poa compressa. Canada Blue Grass
Poa pratensis ssp. *pratensis.* Kentucky Blue Grass
Polygonum convolvulus. Black Bindweed
Polygonum persicaria. Lady's Thumb
Polygonum sagittatum Arrowleaved Tear-Thumb
Potentilla argentea. Silvery Cinquefoil
Potentilla canadensis. Old Field Cinquefoil
Potentilla inclinata. Downy Cinquefoil
Potentilla norvegica. Rough Cinquefoil
Potentilla recta. Erect Cinquefoil
Prunella vulgaris ssp. *vulgaris.* Selfheal
Ranunculus abortivus. Kidney-leaf Buttercup
Ranunculus acris. Field Buttercup
Rudbeckia hirta. Black-eyed Susan
Rumex acetosella ssp. *acetosella.* Sheep Sorrel
Rumex crispus. Curly Dock
Sanicula marilandica. Black Snakeroot
Setaria pumila. Yellow Foxtail
Setaria. viridis. Green Foxtail
Silene vulgaris. Bladder Campion
Sisymbrium officinale. Hedge-Mustard
Sisyrinchium angustifolium. Blue-eyed Grass
Solidago caesia. Blue-stemmed Goldenrod

TABLE 1. *(continued)*

Solidago canadensis. Canada Goldenrod
Solidago gigantea. Tall Goldenrod
Solidago juncea. Early Goldenrod
Solidago nemoralis ssp. *nemoralis*. Gray Goldenrod
Solidago rugosa. Rough-stemmed Goldenrod
Sonchus asper ssp. *asper*. Spiny Sow-thistle
Spiranthes romanzoffiana. Hooded Ladies' Tresses
Stellaria borealis ssp. *borealis*. Northern Stitchwort
Stellaria graminea. Stitchwort
Stellaria media. Chickweed
Taraxacum officinale. Dandelion
Teucrium canadense ssp. *canadense*. Germander
Thlaspi arvense. Field Pennycress
Tragopogon dubius. Goatsbeard
Tragopogon pratensis ssp. *pratensis*. Showy Goatsbeard
Trifolium aureum. Yellow Clover
Trifolium campestre. Smaller Hop Clover
Trifolium hybridum. Alsike Clover
Trifolium pratense. Red Clover
Verbascum thapsus. Common Mullein
Verbena hastata. Blue Vervain
Veronica serpyllifolia ssp. *serpyllifolia*. Thyme-leaved Speedwell
Vicia cracca. Cow Vetch
Vicia sativa ssp. *nigra*. Common Vetch
Vicia tetrasperma. Slender Vetch
Viola sp. Violet

Larval outbreaks are considered to affect the successional pathway in the Opinicon fields in a model developed from our data by Blatt et al. (2001). When insect herbivory on grasses in old fields was studied by Brown et al. (1988), *Elymus repens* was the grass species most affected by Homoptera/Auchenorrhycha; these authors considered that both texture and structure of the successional vegetation were affected by the insects.

The initial seed mix contained *Medicago sativa* ssp. *sativa* (Alfalfa) and possibly *Trifolium pratense* (Red Clover) which have persisted in the fields. *Medicago sativa* frequency was 3-5% in 1976-1980, rose to 12% in 1983 and fell again to 2% in the 1990s. *Trifolium pratense* frequency was 35% in 1976, fell to less than 8% during 1980-1995 and rose again to 22% in 1998. *Trifolium aureum, Trifolium campestre* and *Trifolium hybridum* were recorded occasionally.

Vetches (*Vicia sativa* ssp. *nigra*, *Vicia cracca,* and *Vicia tetrasperma)* became more frequent in later years with a maximal frequency of 69% for *Vicia cracca* in 1987. Possibly these straggling plants benefited from the cessation of mowing. Other legumes recorded were *Melilotus alba, Melilotus officinalis* and *Medicago lupulinus*, randomly distributed except for *Medicago lupulina*, which was most frequent in 1976-1979 in the ploughed plots.

Macroforb areas of the fields have been and are dominated by *Solidago canadensis* (Canada Goldenrod), which we observed to spread by both seeds and rhizomes. Its importance in old field succession in North America has been widely reported (e.g., Dale et al. 1966; Goldberg and Gross 1988). Percentage frequency of *Solidago canadensis* in all plots during 1976-1998 is shown as mean values in Table 2, starting with minimal values in 1976 and reaching a maximum in 1987-1988. Frequencies of *Solidago nemoralis* (Old Field Goldenrod), *Solidago caesia* (Blue-stemmed Goldenrod), and *Euthamia graminifolia* (Grass-leaved Goldenrod), also given in Table 2, were higher in the 1980s than in the 1970s or 1990s. When the three sets of plots were compared, *Solidago canadensis* and *Solidago caesia* were found to be most frequent in the S plots (during 1976-1998 the mean frequency of *Solidago canadensis* in S plots was 47%, in the P plots 37% and in the G plots 26%). *Solidago nemoralis* and *Solidago juncea* were generally more frequent in sandy dry plots. This distribution may be explained by different soil moisture tolerances among the congeners (Werner and Platt 1976).

Cover values for *Solidago canadensis* ranged from 1 to 100%. Patterns were not synchronous between plots. Two examples are shown. Figure 3 shows Plot P2, with three irregular peaks of goldenrod cover, and Figure 2 shows Plot G1 with only three years of sporadic goldenrod cover. The plot with three peaks and lows (Figure 3) had a periodicity also observed in other plots, while others had one, two, or three-and-a-half episodes. Some sandy plots similar to that shown in Figure 2 failed to develop dense *Solidago* cover, and did not have a series of highs and lows.

We have found that the cover of *Solidago canadensis* was negatively and significantly correlated with larval density of three species of *Trirhabda* beetles in the field (McBrien et al. 1983; Blatt et al. 2001). *Trirhabda virgata* was most abundant. Field experiments showed that effects on biomass and cover similar to those caused by larval grazing could be produced by manual defoliation (McBrien and Harmsen 1987).

Within a field, beetle outbreaks were not synchronous between plots. Outbreaks in the two fields also occurred at different times. In the P/G field, years with several plot peaks of *Solidago* cover were 1980, 1981, and 1985, and years with most lows were 1976, 1985 and 1998. That both peaks and lows occurred in 1985 shows the small scale of the beetle outbreaks, sometimes confined to a plot 100 m^2. Outbreaks on a much larger scale have been reported, for example, on a scale of several hectares (Werner et al. 1980), and over two hundred insect species have been reported on *Solidago canadensis*.

Macroforbs growing to the same size as some goldenrods included the asters *Aster umbellatus* (Flat-topped White Aster) and *Aster novae-angliae* (New

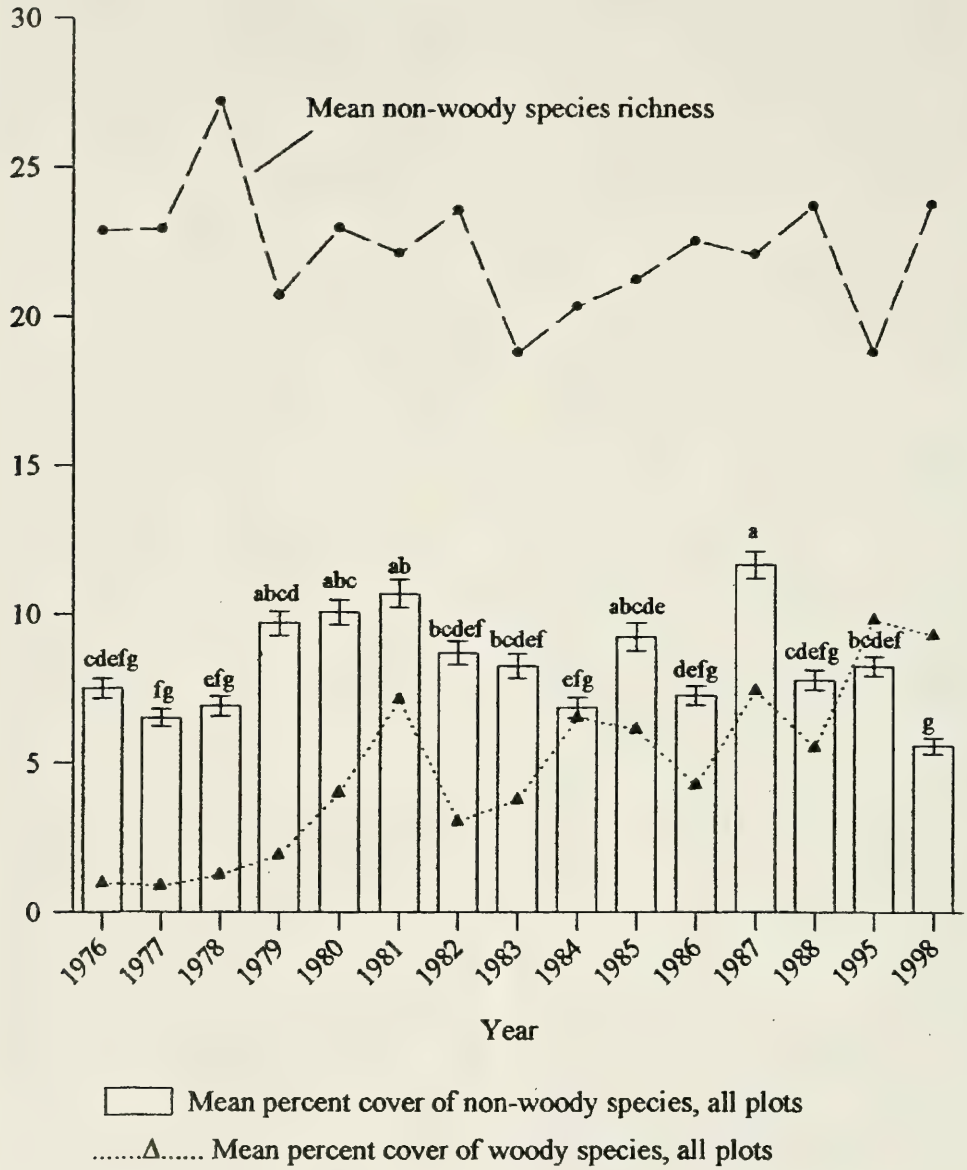

FIGURE 1. Comparison of woody and non-woody vegetation. Mean species richness of herbaceous plants in 27 plots (species number/100 m^2) for the years 1976-1988, 1995 and 1998 is shown by dots. Mean percent cover of non-woody species in all plots in September is shown in the histogram; means which do not share the same letter are significantly different. Mean percent cover of woody species in all plots is indicated by a dotted line with triangles.

England Aster). During the years of observation the percentage frequency of these two species increased (Table 2). Three smaller species, *Aster lanceolatus* (included in *Aster simplex* in Table 2), *Aster lateriflorus* and *Aster ontarionis*, have been lumped together because they were generally intermingled in straggling clumps which also increased in frequency. *Aster cordifolius* (Heart-leaved Aster) and *Aster urophyllus* (Arrow-leaved Aster), both of which are shade-tolerant (Semple et al. 1996), had low frequency. Five of the aster species found in the Opinicon fields were recorded by Maycock and Guzikowa (1984).

When all aster species are lumped together, mean annual cover ranged from 1 to 45%. Comparing dif-

TABLE 2. Mean percentage frequency of selected herbs in all plots during 1976-1988, 1995 and 1998 (n = 162)

Year	1976	1977	1978	1979	1980	1981	1982	1983	1984	1985	1986	1987	1988	1995	1998

Aster ericoides	0	1	3	0	0	0	0	0	0	0	0	2	0	0	0

ferent plots, patterns of peaks and lows like those observed in *Solidago canadensis* occurred in some plots, but with a longer periodicity ranging up to ten years. Since these fluctuations in cover were not synchronous between plots or fields, it is possible that they were due to herbivory, like the changes in *Solidago* and grasses.

Two species of horsetail, *Equisetum arvense* and *Equisetum hyemale*, were present in the P/G field throughout 1976-1998 with a combined mean percentage frequency of 68%. Both species were most frequent in sandy plots and are locally common in disturbed habitats such as sandpits (Crowder et al. 1997). Cover did not exceed 29% for the two species combined in any year, and was generally low.

Mean frequency of *Taraxacum officinale* ranged from 13% in 1981 to 37% in 1988. Dandelions were present in all three sets of plots every year, with highest frequency in the S and lowest in the G plots. The rosette growth form of *Taraxacum officinale* is similar to that of many genera in the plots, such as *Hieracium* spp. and *Antennaria parlinii*, and probably facilitates early spring growth.

Sedges, *Carex* spp., were observed in all years and in all sets of plots, but were not analysed because of difficulty in distinguishing non-flowering stages. *Carex granularis, Carex laxiflora* and *Carex normalis* were relatively abundant. Mean annual frequency of all species was 39% and most plants were found in plots with high moisture content (Crowder and Harmsen 1998). Mean cover was less than 2% until 1979, rose to 7% in 1987, and then declined again.

Species which increased in both frequency and cover during 1976-1998 included *Asclepias syriaca* (Milkweed) and *Ranunculus acris* (Field Buttercup). Species which declined in both frequency and cover included *Rumex acetosella* ssp. *acetosella* (Sheep's Sorrel), *Ambrosia artemisiifolia* (Ragweed), *Oxalis stricta* (Yellow Wood Sorrel), and *Prunella vulgaris* ssp. *lanceolata* (Self-Heal). *Rumex acetosella* and *Ambrosia artemisiifolia*, which are weedy species, were mostly in the ploughed plots, whereas *Prunella vulgaris* was initially concentrated in grass plots. A minor component with low cover value but high frequency (40-50%) was *Potentilla recta* (Erect Cinquefoil).

When grass cover was lowered by grazing of *Thymelicus lineola*, feeding preferentially on *Phleum pratense*, cover of *Solidago* and *Aster* spp. in both fields increased rapidly; they then maintained their dominance at levels equal to that of *Poa pratensis*, preventing the recovery of *Phleum pratense* (Henderson 1986; Blatt et al. 2001; Blatt et al. 2003). In addition to interactions between grasses and goldenrods, other layers were affected. For example, when the cover of *Solidago canadensis* was decreased by the feeding of beetle larvae a chamaephyte, *Fragaria virginiana* (Wild Strawberry), showed significantly increased cover (McBrien et al. 1983). This finding

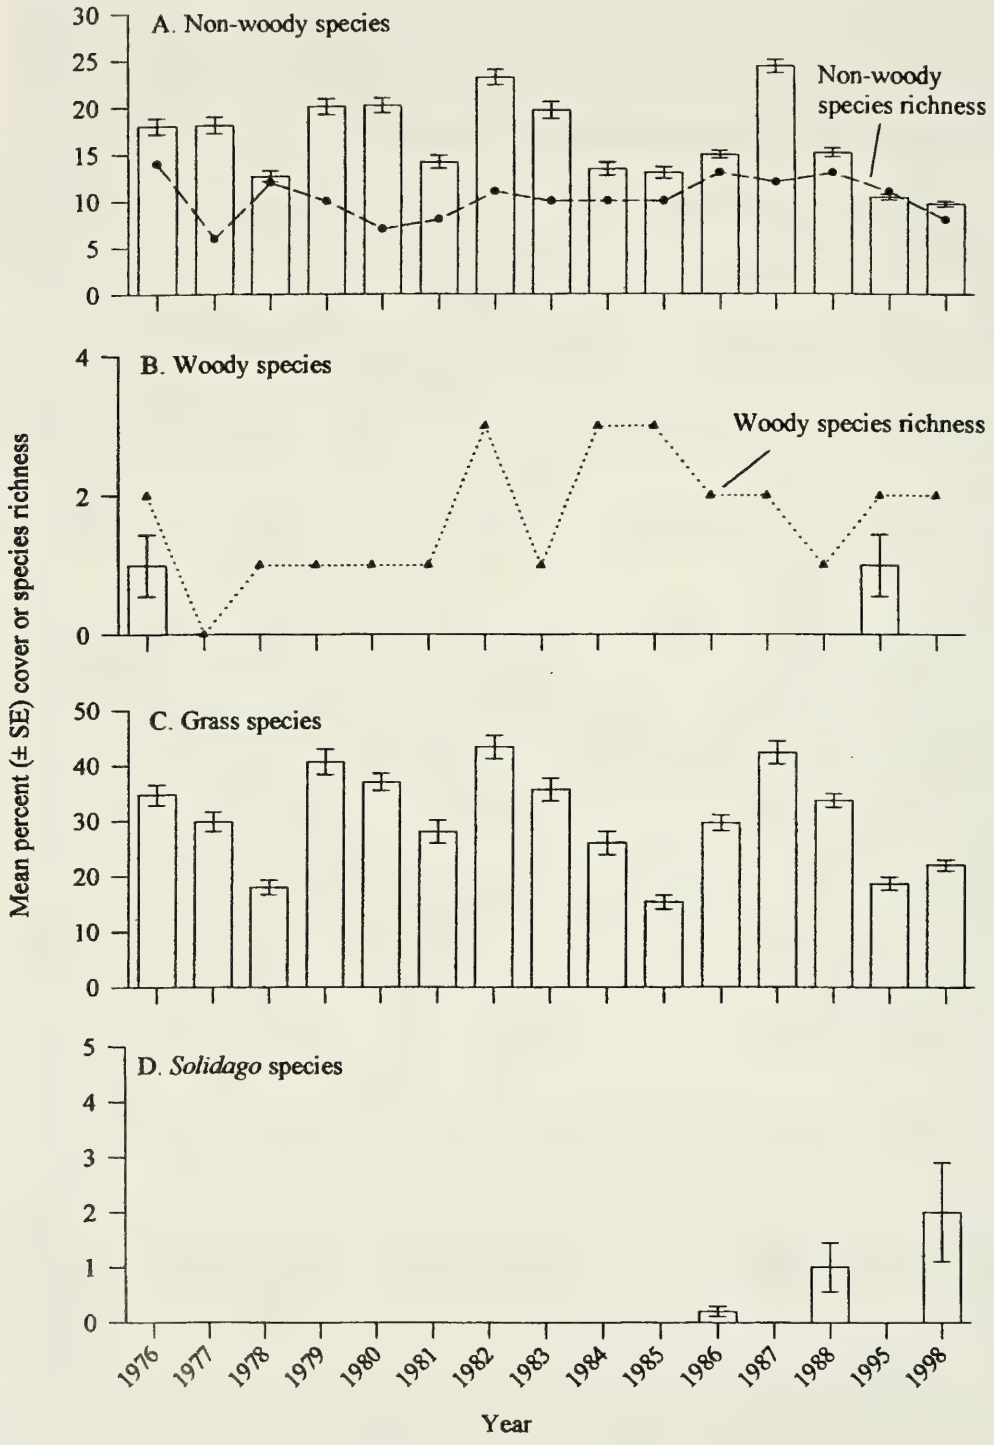

FIGURE 2. Conditions in grass plot G1 during 1976-1988, 1995 and 1998. 2A shows mean percent cover of non-woody species, and non-woody species richness (species number/100 m^2). 2B shows cover and species richness of woody plants. 2C shows mean cover of all grass species. 2D shows *Solidago* species cover, which was only present in 1986, 1988 and 1998.

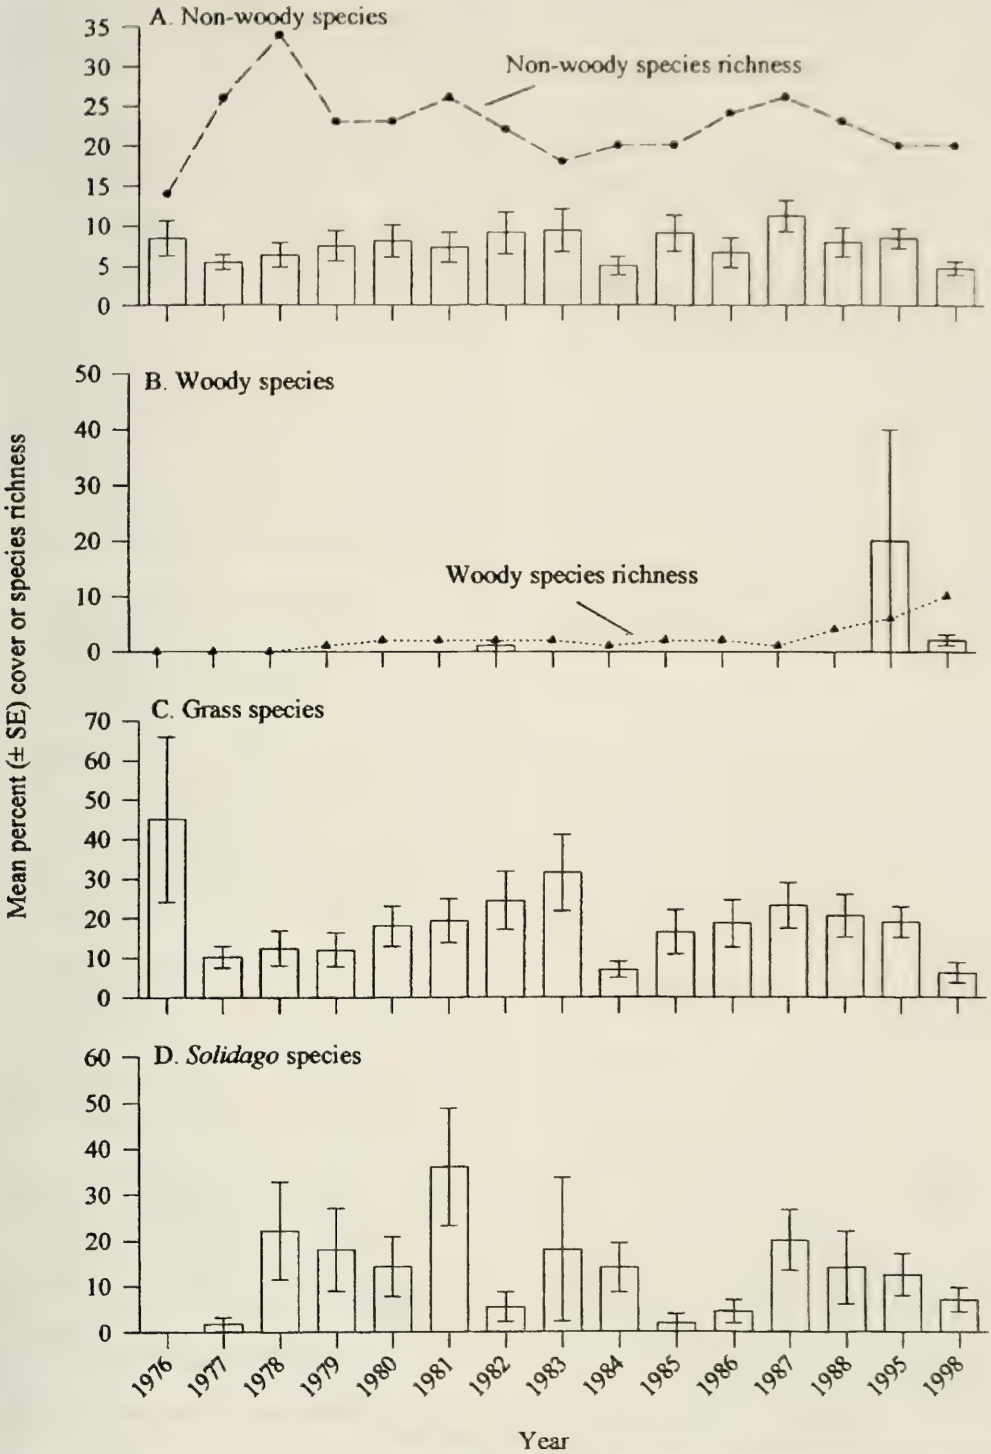

FIGURE 3. Conditions in ploughed plot P2 during 1976-1988, 1995 and 1998. 3A shows non-woody species richness (species/100 m^2) and mean annual percent cover. 3B shows woody species richness and cover. 3C shows cover of all grass species with peaks and lows. 3D shows cover of *Solidago* species with peaks and lows.

has been confirmed elsewhere by Carson and Pickett (1990) who attributed it to decreased shading by the macroforb.

Shade-tolerant herbs in the plots included *Sanicula marilandica* (Black Snakeroot), *Teucrium canadense* ssp. *canadense* (Germander), *Lactuca canadensis* (Wild Lettuce), *Solidago caesia* and *Aster cordifolius*. The increase in woody plants documented by Crowder and Harmsen (1998) could have been expected to create conditions favouring increases of such shade-tolerant species. They did not, however, increase in frequency or cover over time. Presumably shaded microniches under plants such as goldenrods were present in early years and were later replaced by similar conditions under shrubs or trees.

Acknowledgments

Partial funding was received from the Ontario Ministry of Natural Resources; we particularly thank R. Wagner, S. Strobl and P. Neave. Preliminary analysis of field results was done by C. Vardy, and we thank her and the many others who helped with field surveys. Our thanks are due to J. Pringle and P. Catling who identified some of the composites and sedges. We are grateful for the continued support of Queen's University Biology Station.

Chhin, Sophan, and G. Geoff Wang. 2007. Growth of White Spruce, *Picea glauca*, seedlings in relation to microenvironmental conditions in a forest-prairie ecotone of southwestern Manitoba. Canadian Field-Naturalist 121(2): 191–200.

The influence of microenvironmental conditions on the growth performance (i.e., diameter and height growth) of White Spruce [*Picea glauca* (Moench) Voss] seedlings was examined within three contrasting habitats: White Spruce tree islands, open prairies and Trembling Aspen (*Populus tremuloides* Michx.) groves. These habitats exist within a disjunct occurrence of White Spruce at its southern limit of distribution in three mixed-grass prairie preserves in the Spruce Woods Provincial Park within the forest-prairie ecotone of southwestern Manitoba. Microenvironmental measurements (i.e., light, temperature, relative humidity, soil moisture) were obtained on 10 sites in each of the three habitats and growth characteristics of 60 White Spruce seedlings were measured in each of three habitats. Higher light and soil temperature conditions occurred within the open prairie. In contrast, lower light and soil temperature conditions occurred under the tree canopy of aspen groves and the northern aspect of spruce islands, which moderated the effect of the dry regional climate. Height growth did not vary significantly among the three habitats. The greater diameter growth and decreased slenderness of White Spruce seedlings in the open versus the shaded habitats appears to be a result of increased photosynthesis at higher light intensity and may also represent a morphological adaptation to withstand the effect of increased wind exposure. The increased slenderness of White Spruce in the shaded habitats appears to be a morphological adaptation of increasing carbon allocation towards height growth and thus maximizing effective competition for light.

Key Words: White Spruce, *Picea glauca*, prairie-forest boundary, aspen parkland, growth, microenvironment, seed-seedling conflicts, Manitoba.

In the prairie provinces of Canada, the southern limit of conifer species occurs in the aspen parkland. Vegetation in the aspen parkland is dominated by Trembling Aspen (*Populus tremuloides* Michx.) which exists as continuous forest or as groves intermixed with prairie (Bird 1961). The aspen parkland is a transitional vegetation zone (ecotone) between prairie to the south and boreal forest to the north (Bird 1961; Zoltai 1975). The prevailing regional climate of the aspen parkland and mixed-grass prairie in southwestern Manitoba is characterized by low precipitation, high summer temperatures, and dry winds, any of which may be limiting factors to plant distribution and growth (Coupland 1950). For instance, previous studies which examined the radial growth-climate association of White Spruce [*Picea glauca* (Moench) Voss] in the aspen parkland region demonstrated that growth was restricted by moisture deficiency exacerbated by temperature-induced drought stress (Chhin et al. 2004).

Tree invasion into prairies under the dry climate of the aspen parkland must be assisted by favorable microenvironments or "safe sites" (Harper 1977; De Steven 1991a, 1991b; Kellman and Kading 1992; Chhin and Wang 2002). In many prairie environments, shrubs are known to facilitate tree seedling establishment (Callaway 1995; Chambers 2001) by suppressing grass competition (Bird 1961; Werner and Harbeck 1982) and by providing protective conditions from abiotic forces such as fire (Coupland 1950; Bird 1961). The presence of previously established trees in open prairie not only reduces evaporative water loss from plants (Kellman and Kading 1992) but also increases soil moisture and nutrients (Wilson and Kleb 1996; Li and Wilson 1998; Wilson 1998). Furthermore, woody canopies modify the understory microclimate, including shading, interception of precipitation, litter fall (Vetaas 1992), reduced wind speed (Archibold et al. 1996), lower soil temperature, and higher humidity (Carlson and Groot 1997).

Within the aspen parkland of southwestern Manitoba, White Spruce typically establishes under a Trembling Aspen canopy and will eventually replace aspen to form White Spruce forests in the absence of disturbances (Bird 1961). Abundant White Spruce seedlings and saplings are commonly observed in many Trembling Aspen stands, indicating a favorable environment for regeneration. However, White Spruce can occasionally invade open prairies within previously established Creeping Juniper (*Juniperus horizontalis* Moench) patches (Bird 1961; Chhin and Wang 2002). Creeping Juniper is believed to reduce mortality of White Spruce seedlings from prairie ground fires (Bird 1961). The progressive recruitment and establishment of White

Spruce in the open prairie results in the development of White Spruce tree islands which are surrounded by mixed-grass prairie. The islands have an asymmetric spatial structure since White Spruce regeneration is concentrated on the northern aspect of the tree islands. Chhin and Wang (2002) determined that the best environment for White Spruce regeneration within mixed-grass prairie was under the influence of established White Spruce trees (i.e., on the north vs. south aspect and between 4 to 12 m from the spruce island centre, and close association with Creeping Juniper). Other studies have also observed growth of White Spruce in the aspen parkland region on favourable microenvironments such as the north side of trees, north side of river valleys, and other north-facing slopes and microsites (Zoltai 1975; Hogg 1994; Hogg and Schwartz 1997). Together, these previous studies suggested that the suitability for White Spruce establishment decreased from aspen groves (i.e., under a Trembling Aspen canopy), to White Spruce tree islands (i.e., under the influence of established White Spruce trees) and to Creeping Juniper patches in open prairies. However, environmental conditions associated with these habitats have not been documented and how White Spruce growth differs among these habitats has not been quantified.

Ecotones are expected to be sensitive to climatic change, and the environment of the aspen parkland is believed to characterize the future boreal forest under a warmer climate (Hogg 1994). Moderated microenvironmental conditions may potentially serve as microscale refugia or "safe sites" (Harper 1977) for tree seedlings in the context of global warming during the 21st century (IPCC 2007) within a climatically sensitive ecotonal region of the aspen parkland. The first objective of this study was to examine the microenvironmental conditions of five habitats within the aspen parkland of the Spruce Woods Provincial Park (SWPP) in southwestern Manitoba, Canada. These habitats include one habitat in Trembling Aspen groves (AG) [interior (AG-I)], two habitats in White Spruce tree islands (SI) [northern (SI-N) vs. southern (SI-S) aspect], and adjacent to the islands, two habitats in open prairies (OP) [ground vegetation dominated by grass (OP-G) vs. juniper (OP-J)]. The second objective of the study was to compare White Spruce seedling growth (i.e., height and diameter) among three habitats (OP-J, SI-N, and AG-I; seedlings were not sampled in OP-G and SI-S since it was extremely rare to find them in these habitats) and relate growth patterns to the microenvironmental patterns.

Methods

Study area

The study was conducted in the SWPP which is located in southwestern Manitoba (49°40'N, 99°15'W) (Figure 1). The nearest meteorological station with a long-term climatic record is the Brandon Agriculture Station (49°52'N, 99°59'W), which is located about 88.5 km northwest of the SWPP. The area experienced, for the reference period of 1971-2000, an average annual temperature of 2.4°C (Environment Canada 2002). Average annual precipitation amounts to 474.0 mm, with 78.3% as rainfall and the remainder as snowfall. Precipitation peaks in June (75.7 mm), and temperature is highest in July, reaching a daily mean of 18.9°C (Environment Canada 2002). Vegetation in the park is characterized as the aspen-oak grove of the boreal forest region (Rowe 1972). A sandhill, mixed-grass prairie community unique to the aspen parkland is located in the SWPP and consists of Trembling Aspen intermixed with a disjunct population of White Spruce at its southern limit of distribution (Schykulski and Moore 1997). The SWPP resides over an extensive belt of deltaic sands (6500 km^2) created 12 000 years B.P. when a predecessor of the Assiniboine River flowed into glacial Lake Agassiz. The SWPP is located on this delta, and this area has been designated as the Assiniboine Delta Natural Region (ADNR). Within the ADNR, the SWPP contains some of the best examples of the few remaining remnants of native mixed-grass prairie, since most of the native prairie in the ADNR has been lost to agricultural cultivation. The mixed-grass prairie preserves of the SWPP are protected under the mandate of the Prairie Management Plan of Manitoba Conservation in order to preserve its unique and rich biodiversity of plants, insects, and wildlife (Schykulski and Moore 1997).

Natural and anthropogenic disturbances have contributed to the landscape mosaic of the aspen parkland (Bird 1961). In pre-European settlement times, disturbances included fire which occurred naturally or started by Native people in order to maintain the prairie environment for the Bison (*Bison bison* L.). Grazing by herbivores such as Bison and Elk (*Cervus canadensis* Erxl.) prevented the encroachment of the forest onto the prairie. European settlement contributed to the decline of the Bison population due to hunting, livestock grazing, intensive agriculture, and the policy of fire suppression (Bird 1961). The reduction of grazing and fire pressure has resulted in the encroachment of the forest onto the prairie. A policy of fire suppression continues within the SWPP, with intermittent prescribed burning permitted within the mixed-grass prairie preserves (Schykulski and Moore 1997).

Site selection

The study was located in three mixed-grass prairie preserves north of the Assiniboine river: Picnic, Aspen Bluff, and Jackfish prairie (Figure 1). Ten White Spruce islands (SI) with adjacent open prairie (OP), and ten aspen groves (AG) were selected using aerial photographs and field reconnaissance. Four sites of each habitat were chosen in Picnic prairie and Aspen Bluff prairie, whereas two sites of each habitat were selected in Jackfish prairie. Although the occurrence of habitat types could be confounded with environmental con-

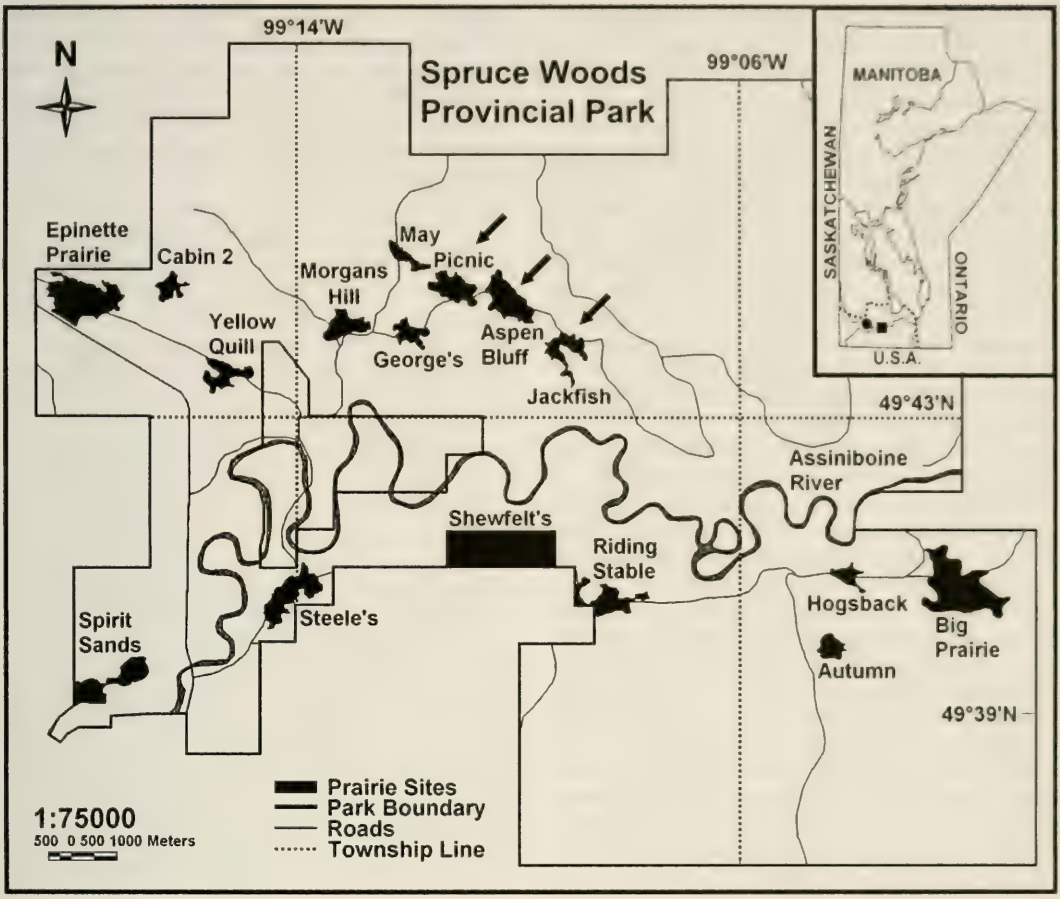

FIGURE 1. Regional setting of the Spruce Woods Provincial Park (SWPP) (■) and the city of Brandon (●) in southwestern Manitoba shown in the inset map. The southern continuous limit of White Spruce according to Farrar (1995) is indicated by the dashed line. The arrows in the enlarged map of the SWPP indicate the mixed-grass prairie preserves in which the study was conducted. Adapted from Schykulski and Moore (1997).

ditions not sampled, the study area is comprised of homogeneous soil conditions which minimize the degree of confounding (Schykulski and Moore 1997). The soil is uniformly sandy and nutrient poor with a poorly developed thin organic layer. Furthermore, it was ensured that sites selected occurred on uniformally flat topography. Additional criteria for spruce island selection were that islands be at least 20 m apart from each other or from the forest edge. Open prairie containing patches of grass and Creeping Juniper were selected adjacent to but at least 20 m away from a spruce island or forest edge. Aspen groves containing understory development of juvenile White Spruce were selected.

Sampling design

The sampling design in a White Spruce island consisted of extending a 12 m transect line on each of the north and south side of a reference tree (i.e., the largest dominant tree of the spruce island). One habitat was selected on the northern (SI-N) and one on the southern (SI-S) aspect of each spruce island. Each SI-N and SI-S habitat was represented by three circular plots (one-meter radius). The centres of the three plots corresponding to each of the SI-N and SI-S habitat were placed 4, 8, and 12 m from the reference tree. Two habitats, a grass habitat (OP-G) and a juniper habitat (OP-J), were selected in open prairie adjacent to White Spruce islands. Each OP-G and OP-J habitat was represented by three randomly placed circular plots (one-meter radius). One habitat was selected in the interior of each Trembling Aspen grove (AG-I) such that there was at least a ten meter buffer zone to the aspen stand edge. The AG-I habitat was represented by six randomly placed circular plots (one-meter radius). Two different habitats were sampled in spruce islands and open prairies because previous studies clearly indicated differences in the establishment of White Spruce seedlings (Chhin and Wang 2002). OP-G generally had no seedling establishment while OP-J occa-

sionally supported seedlings. Many more seedlings were found in SI-N (0.22 seedlings m^{-2}) compared to SI-S (0.008 seedlings m^{-2}).

Data collection

Microenvironment

Solar radiation was measured in the morning (10:00 – 12:00 h) and afternoon (14:00 – 16:00 h) with an AccuPAR Ceptometer (Decagon Devices, Pullman, USA). Measurements for these two periods were averaged. Light measurements were taken at a height of 1.3 m from the north, east, south and west sides of each circular plot. Light intensity of each circular plot was expressed as an average of these four measurements. Light intensities in spruce islands and aspen groves were expressed as percentages of the average light intensity of the open prairie.

Air temperature and relative air humidity (15 cm above ground) were measured using digital thermohygrometers (sensor size: 1 cm diameter) (Barnant, Barrington, USA). Soil (15 cm below the surface) temperature was measured with a thermocouple penetration probe (sensor size: 0.5 cm diameter) and surface temperature was measured with a thermocouple surface probe (sensor size: 1.25 cm diameter) (Barnant, Barrington, USA). These measurements were taken in the centre of each plot and were measured once between 10:00 and 16:00 h.

Surface soil moisture was measured at the centre of each plot with a digital Theta probe soil moisture sensor (Delta-T Devices, Cambridge, UK). The prongs of the Theta probe have a length of 6 cm and thus measure soil moisture of the mineral soil within the top 6 cm. A profile probe was used to measure soil moisture of the mineral soil within the top 40 cm with sensors positioned at the depths of 10, 20, 30 and 40 cm below the soil surface (Delta-T Devices, Cambridge, UK). The profile measurements were taken in an augered hole near the centre of each plot. Due to the limitations in time and instrumentation, not all plots of each habitat could be sampled. Thus, in spruce islands, profile measurements were taken in a single plot 8 m from the reference tree in each of the SI-N and SI-S habitat. One plot of each juniper habitat and one plot of each grass habitat were randomly selected for measurements in each open prairie site. Two plots of the aspen grove interior habitat were randomly selected from each aspen grove. Three profile readings were taken at each plot by rotating the profile probe 120° after each individual reading (Delta-T Devices, Cambridge, UK). The profile measurements of each plot were expressed as an average of these three measurements. Surface and profile moisture measurements were taken between 10:00 and 16:00 h.

All microenvironmental variables were measured on sunny clear days at least 24 hours after any rainfall. These conditions ensured that the habitats were contrasted as much as possible. Profile soil moisture was measured on 4 June 2002. Temperature (soil, surface and air), relative air humidity and surface soil moisture were measured on 5 June 2002. Light intensity was measured on 8 July 2002. The midsummer months of June and July represent typical growing season conditions, and previous studies indicated that precipitation and mean and maximum temperature in the months of June and July strongly affected White Spruce growth (Chhin et al. 2004).

Seedling growth

Six seedlings (< 2 m tall) were destructively sampled from each of the same 10 spruce islands and 10 aspen groves used to collect the microenvironmental data. For each of the three circular plots in the northern aspect (i.e., SI-N habitat) of spruce islands, two seedlings which were nearest to the centre of a circular plot were selected for sampling. Similarly, for each of the six circular plots within aspen groves, one seedling nearest to the centre of a circular plot was selected for sampling. As the open prairie sites used to collect the microenvironmental data did not contain sufficient recruitment of White Spruce, each of the three prairie preserves was surveyed and a total of ten sampling locations were selected which contained greater than six seedlings clustered within a circular area of 10 m radius. Four sampling locations were chosen in Picnic prairie and Aspen Bluff prairie, whereas two sampling locations were selected in Jackfish prairie. The sampling locations were also at least 20 m from the forest edge, White Spruce tree islands or Trembling Aspen groves. At each sampling location within the prairie preserves, the seedling nearest to six randomly chosen points was selected for sampling. All seedlings collected in spruce islands and open prairies were growing within juniper patches.

Height and root collar diameter (RCD) were recorded for each seedling. A section was taken from the root collar of each destructively sampled seedling. Each root collar section was prepared following standard dendrochronological techniques (Yamaguchi 1991; Stokes and Smiley 1996). That is, all wood samples were sanded with progressively finer grades of sandpaper to highlight ring-width patterns. All root collar sections were crossdated under a binocular microscope to ensure accuracy of age determination.

Data analysis

Microenvironment

The Theta probe and profile probe measures the volumetric soil moisture content (θ) which is the ratio between the volume of water present and the total volume of the soil sample. For the Theta probe measurements, units of soil moisture in θ are proportional to voltage (V) via the following linear relationship (Delta-T Devices, Cambridge, UK):

$$[1] \qquad \theta = \frac{[1.1 + 4.44V] - a_0}{a_1}$$

where a_0 and a_1 represent constants which characterize different soil types. Based on a large number of soil samples, generalized values of the parameters

are $a_0 = 1.6$ and $a_1 = 8.4$ for mineral soils (Delta-T Devices, Cambridge, UK); the value of these constants was used in converting the soil moisture of the mineral surface layer from units in V to θ. Similarly, for the profile probe measurements, the following linear relationship was used to convert the soil moisture of the mineral soil at the depths of 10, 20, 30 and 40 cm below the soil surface from units in V to θ (Delta-T Devices, Cambridge, UK):

$$[2] \qquad \theta = \frac{[0.67 + 10.8V] - a_0}{a_1}$$

where the generalized constants for mineral soils are $a_0 = 1.6$ and $a_1 = 8.4$ (Delta-T Devices, Cambridge, UK). Volumetric moisture content is a dimensionless parameter expressed as a percentage (% vol) or as a ratio ($m^3\ m^{-3}$). Equations 1 ($\theta < 50$ % vol) and 2 ($\theta < 30$% vol) are suitable to convert moisture readings in V to % vol for soils of low moisture content, which was the case in this study.

For the subsequent statistical analyses, the microenvironmental variables measured in habitats represented by more than one plot were treated as subsamples and were averaged. Except for the temperature data, all microenvironmental parameters with percentage data were log-transformed (LOG_{10} X). Those variables with zero values were log-transformed using: LOG_{10} (X+1). Analysis of variance (ANOVA) followed by Tukey's multiple comparisons (Wilkinson 1990) was conducted on the light data to compare light conditions among the five habitats (SI-N, SI-S, OP-G, OP-J and AG-I) with ten replicates for each habitat. Similarly, ANOVA was conducted on surface, soil and air temperature; relative humidity; surface moisture; and average moisture of all profile depths in order to compare these parameters among the five habitats. For the log-transformed data, the mean values of the microenvironmental variables for each habitat and the lower and upper limits of a 95% confidence interval were back-transformed by taking antilogs (10^X or $10^X - 1$) so that all means and confidence limits could be reported on their original scale of measurement.

Seedling growth

The height/age ratio (i.e., mean annual height growth), RCD/age ratio (i.e., mean annual diameter growth) and height/RCD ratio (i.e., slenderness coefficient) was determined for all seedlings. The six seedlings per site were treated as subsamples and were averaged for each of the ratios. All of the ratios were compared between habitats via ANOVA with 10 replicates for each of the three habitats.

Results

Microenvironment

Light intensity in White Spruce islands was lower in the northern (SI-N, 54.5%) versus southern (SI-S, 79.1%) aspect ($P < 0.05$) (Table 1). Light intensity in the southern island aspect in turn was not significantly different from the open prairie conditions (OP-G and OP-J) (all $P > 0.05$). Light intensity in the aspen grove interior (AG-I, 18.3%) was significantly less than any of the other habitats (all $P < 0.05$).

Soil temperature differed among some of the habitats (Table 1). Soil temperature within spruce islands was lower in the northern (SI-N, 13.5°C) versus southern (SI-S, 16.4°C) aspect ($P < 0.05$). The spruce island habitats (SI-N, SI-S) in turn were not significantly different from soil temperature in the open prairie grass habitat (OP-G, 15.7°C) (all $P > 0.05$). Both the SI-S and the OP-G habitats had significantly greater soil temperature than the open prairie juniper habitat (OP-J, 13.4°C) (all $P < 0.05$). Soil temperature of the aspen grove habitat (AG-I, 10.2°C) was lower than any of the other habitats (all $P < 0.05$). While surface and air temperature did not differ significantly among the habitats they followed similar relative patterns among the habitats as described for soil temperature.

Although relative air humidity was greatest in aspen groves (AG-I, 36.7%), lowest in the open prairie (OP-G, 30.4%; OP-J, 31.8%), and intermediate in spruce islands (SI-N, 32.7%; SI-S, 33.7%) there were no significant differences in relative air humidity among these habitats (all $P > 0.05$) (Table 1).

Surface soil moisture in the northern island aspect (SI-N, 7.1%) was not significantly different from that in the southern aspect (SI-S, 4.7%) ($P > 0.05$) (Table 1). Soil moisture in the southern island aspect in turn was significantly less than in either the open prairie grass (OP-G, 10.9%) or aspen grove (AG-I, 8.9%) (all $P < 0.05$). Surface soil moisture of the open prairie juniper (OP-J, 8.8%) habitat was not significantly different from the other habitats (all $P > 0.05$). Average soil moisture of all profile depths in the SI-S (1.8%) habitat was less than that in the AG-I (8.0%) habitat (all $P < 0.05$) (Table 1).

Seedling growth

White Spruce seedlings in the open prairie and spruce islands established exclusively amongst Creeping Juniper. Seedlings in aspen groves established exclusively on forest floor litter (i.e., Trembling Aspen leaves). General seedling attributes are shown in Table 2. Mean annual height growth of seedlings did not differ significantly among the three habitats (all $P > 0.05$) (Figure 2). Mean annual diameter growth differed significantly amongst the three habitats (all $P < 0.05$) (Figure 3). Open prairie seedlings had the greatest diameter followed by seedlings from spruce islands and then aspen groves. The slenderness coefficient also differed significantly amongst the three habitats (all $P < 0.05$) (Figure 4). Aspen grove seedlings were most slender, followed by seedlings from spruce islands and then open prairies.

Discussion

Less exposure to solar radiation was expected under the canopy of aspen groves and spruce islands because of shading. Light conditions under aspen canopy

TABLE 1. Microenvironmental conditions of Trembling Aspen groves [interior (AG-I) habitat], and White Spruce tree islands [north (SI-N) and south (SI-S) aspect habitat] with adjacent open prairies [grass (OP-G) and juniper (OP-J) habitat]. The lower and upper limits of a 95% confidence interval of the mean of ten replicates per habitat are shown in parentheses. For each microenvironmental variable, habitats with different letters are significantly different ($P < 0.05$). Except for the temperature data, comparisons were made based on log-transformed data. Microenvironmental variables with no letters for each habitat were not significantly different ($P > 0.05$).

TABLE 2. Attributes of White Spruce seedlings from White Spruce tree islands, open prairies, and Trembling Aspen groves. Standard error of the mean in parentheses.

Attribute	Open Prairie	Spruce Island	Aspen Grove
Sample size (n)	60	60	60
Height (cm)	50.4 (4.9)	49.8 (4.6)	69.6 (6.7)
Diameter (cm)	1.66 (0.21)	1.24 (0.13)	1.16 (0.12)
Age (year)	11.4 (0.6)	11.9 (0.7)	15.1 (0.8)

(18.3%) occurred at levels similar to other studies of aspen stands (Archibold et al. 1996: 23%; Carlson and Groot 1997: 18%). The dominant overstory White Spruce trees cast shade onto the understory, with more shade on the northern versus southern aspect. The reduced soil temperature of the northern versus southern island aspect as well as the lowest soil temperature in aspen groves indicated that areas with increased shade were also cooler. This was expected since temperature is generally a function of solar radiation (Archibold et al. 1996; Morecroft et al. 1998). Decreased soil temperature may lead to decreased evapotranspirative demands in the aforementioned shaded areas. In our study, soil temperature in aspen groves was 3.2-5.5°C less than in the open prairie. Other studies have also reported similar levels of reduced soil temperature in aspen (Archibold et al. 1996: 5°C) and other deciduous stands (Morecroft et al. 1998; 2.5°C) compared to adjacent open conditions. Reduced solar radiation has the potential to moderate the microclimate in forest/grassland ecosystems and thus provide a less hostile environment for tree regeneration and growth (Zoltai 1975; Hogg 1994; Breshears et al. 1997; Hogg and Schwartz 1997).

While light and soil temperature varied significantly among different habitats, surface and air temperature as well as relative air humidity did not. Morecroft et al. (1998) also found that a deciduous forest canopy had a greater effect on reducing soil temperature than air temperature. Although air temperature and humidity did not differ significantly among the habitats, the lower level of air temperature in aspen groves (2.5-2.6°C lower) versus the open prairie was comparable to that observed in other aspen (Archibold et al. 1996: 1.5°C lower; Carlson and Groot 1997: 0.7°C) and deciduous stands (Morecroft et al. 1998: 0.6-0.9°C). Relative humidity was 4.9-6.3% higher in aspen groves compared to the open prairie. This is comparable to a study in the aspen parkland of Saskatchewan by Archibold et al. (1996). They observed that average relative humidity in the summer was generally 4% higher inside than outside an aspen grove. Higher air humidity

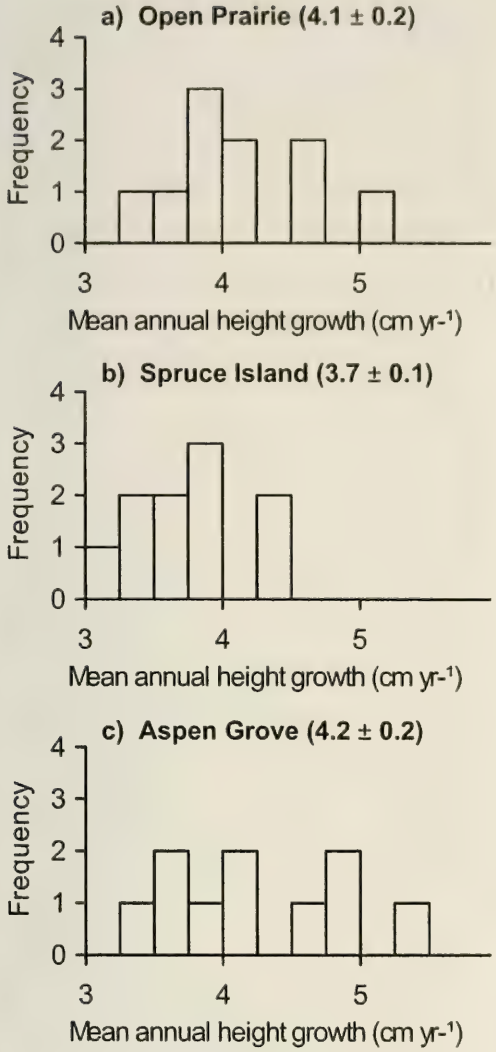

FIGURE 2. Frequency histogram of height/age ratio (i.e., mean annual height growth) of White Spruce seedlings from open prairies (a), White Spruce tree islands (b), and Trembling Aspen groves (c). Mean ± 1 standard error of the mean of 10 replicates per habitat shown in parentheses. Mean annual height growth did not differ significantly among habitats ($P > 0.05$).

is usually linked to the effects of reduced wind speed and reduced air temperature (Archibold et al. 1996)

Some significant differences in soil moisture were observed among the five habitats. Better moisture retention due to increased shading may explain significantly higher surface and profile soil moisture in aspen groves when compared to SI-S. Due to different degrees of shading, both soil surface and profile moisture were also slightly higher on the northern versus southern aspect of spruce islands. These results support the hypothesis of soil moisture retention which asserts that soil moisture is expected to be greater in areas of increased shading (Wilson and Kleb 1996; Li and Wilson 1998; Wilson 1998). The significantly higher soil surface moisture found in OP-G, and the lack of significant difference between open prairies and spruce islands or aspen groves in soil profile moisture are, however, difficult to explain. A possible explanation is that tree or shrub canopies, especially those of conifers, intercept rainfall and thus limit the amount of through-

fall (Vetaas 1992). Although water may also enter soil via stemflow, it has been shown that such water is more likely to infiltrate to deep soil layers to be used by tree species (Parker 1983; Vetaas 1992; Breshears et al. 1997).

Although open prairies represent the worst habitat for White Spruce establishment (Chhin and Wang 2002), they support the best seedling growth. These results support the hypothesis of seed-seedling conflicts which asserts that the habitat requirements for optimal seedling establishment are discordant with that for seedling growth (Schupp 1995). White Spruce did not show any significant differences in height growth amongst the three habitats. In contrast, White Spruce significantly had the greatest diameter growth within the open prairie followed by tree islands and then aspen groves. These results suggest that diameter growth was more responsive to the environmental factors associated with each habitat than height growth. These results are consistent with that of Groot (1999) who reported that diameter growth of young, planted White Spruce was primarily influenced by light availability, whereas height growth exhibited complex relationships with multiple environmental factors.

The larger diameter growth of White Spruce seedlings in the open prairie was not expected given the harsher abiotic microenvironment (i.e., heat stress) of the open prairie compared to the moderated microclimatic conditions within the spruce islands and aspen groves. There are a number of factors which may have contributed to the better diameter growth of seedlings in the open prairie and the lower than expected diameter growth within spruce islands and aspen groves. These factors include the effect of substrate growth conditions, light availability, and morphological adaptations to wind. First, surveying White Spruce seedlings in the open prairie was difficult given the rarity of finding open prairie spruce. Furthermore, those White Spruce individuals that were found grew exclusively in association with Creeping Juniper. Therefore, the better than expected growth in the open prairie may be due to the moderating influence of a Creeping Juniper substrate, and Creeping Juniper is likely providing White Spruce seedlings protective cover from prairie ground fires (Bird 1961). However, seedlings on the northern aspect of spruce islands also established exclusively on juniper. If substrate was a dominant factor influencing diameter growth it is unclear why seedlings from the open prairie and spruce islands would have different diameter growth rates given the same growth substrate.

Corresponding to the diameter growth reduction from OP-J to SI-N to AG-I, the degree of shade increased. The reduced supply of solar radiation could have outweighed the benefits of a moderated microclimate. In other words, while shade is an important moderating microclimatic factor that is conducive to successful White Spruce establishment (Chhin and Wang 2002), shade becomes a limiting factor to subsequent seedling growth. Although ecophysiological

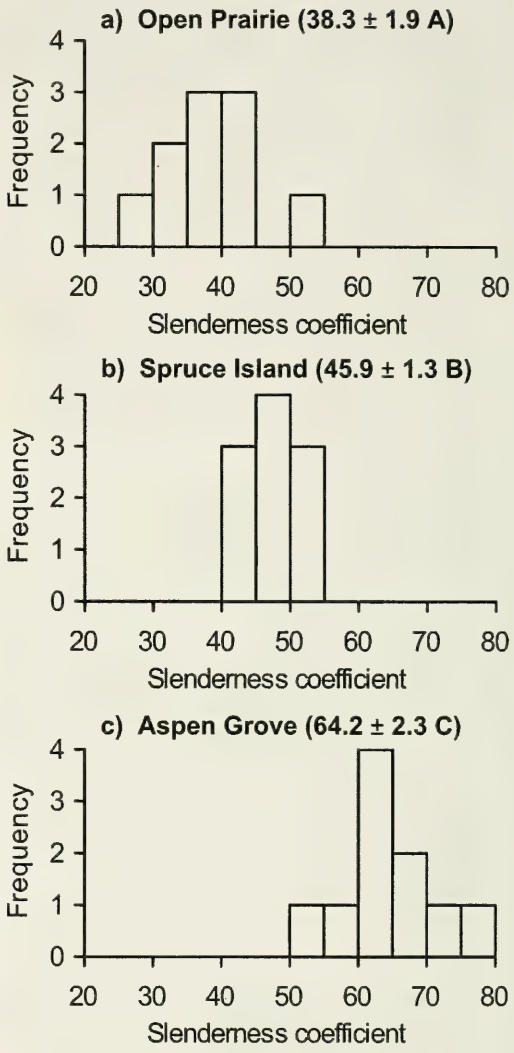

FIGURE 4. Frequency histogram of height/RCD ratio (i.e., slenderness coefficient) of White Spruce seedlings from White Spruce tree islands (a), open prairies (b), and Trembling Aspen groves (c). Mean ± 1 standard error of the mean of 10 replicates per habitat shown in parentheses, and habitats with different capital letters are significantly different ($P < 0.05$).

studies indicate that White Spruce seedlings generally attain maximal height growth at 40% full sunlight (Lieffers and Stadt 1994; Lieffers et al. 1996), seedling diameter growth is greatest at full light intensity (Logan 1969). This may explain the reduced diameter growth of seedlings from the northern aspect of spruce islands which was characterized by light levels of 54.5% of full sunlight. Light levels below 8% generally results in mortality of White Spruce (Lieffers and Stadt 1994). While light conditions under the aspen canopy (18.3%) were greater than this minimal light level, they are

well below that required for maximal diameter growth. Man and Lieffers (1997) also confirmed that light intensity under an aspen canopy was not sufficient to reach the saturation point although light levels were above the compensation point for White Spruce photosynthesis.

Another likely factor which may explain the discrepancy in diameter growth between the three habitats may be morphological adaptations to the effect of wind. Although wind speed was not examined here, it has been shown in another study in Saskatchewan that wind speed in an aspen grove was reduced to 7% of that in adjacent prairie (Archibold et al. 1996). Forest openings are generally characterized by greater wind speeds than forest interiors (Carlson and Groot 1997). Wind causes trees to sway and this can lead to morphological adaptations to resist the effect of wind via increased diameter growth particularly at the base of trees (Kozlowski et al. 1991; Telewski 1995).

The effect of shade and wind is further supported by White Spruce being most slender in aspen groves than in tree islands and the open prairie. These results confirmed our morphological observations in the field. White Spruce seedlings from aspen groves were generally tall and thin, while seedlings from the open prairie were short and thick. White Spruce seedlings from spruce islands were intermediate along this morphological continuum. The morphology of White Spruce under aspen canopy is thus suited for concentrating growth in height to counter the effects of overtopping vegetation (Lieffers and Stadt 1994; Lieffers et al. 1996). The morphology of White Spruce in the open prairie is suited for a more robust stature to withstand the effect of winds during summer (Archibold et al. 1996) and wind and snow abrasion during winter. Wind and snow abrasion have been shown to influence the growth form of open grown spruce at its northern limit of distribution at the tree-line in Churchill, Manitoba (Scott et al. 1993).

The possible discordance in habitat requirements of different developmental stages of White Spruce seedlings may potentially influence successional dynamics in a forest-prairie ecotone in the Spruce Woods Provincial Park. For instance, projecting the initial slow degree of White Spruce seedling establishment in the open prairie onto all developmental stages of White Spruce may underestimate the rate of successional expansion of forest onto prairie, since subsequent seedling diameter growth in the open prairie appears to benefit from high light availability. Nonetheless, further research is required to separate the relative effects of high light availability and increased wind exposure on increased diameter growth of White Spruce seedlings in the open prairie. Projecting the initial establishment success of White Spruce under a Trembling Aspen canopy onto all developmental stages of White Spruce may overestimate the rate of successional replacement of Trembling Aspen by White Spruce, since shade appears to outweigh the benefits of a moderated microclimate for diameter growth of White Spruce seedlings under a Trembling Aspen canopy.

In conclusion, higher light and soil temperature conditions occurred within the open versus shaded habitats. The greater diameter growth and decreased slenderness of White Spruce seedlings in the open versus shaded habitats appears to be a result of increased photosynthesis at higher light intensity and may also represent a morphological adaptation to withstand the effect of increased wind exposure. The increased slenderness of White Spruce in the shaded habitats appears to be a morphological adaptation of increasing carbon allocation towards height growth and thus maximizing effective competition for light. While shade is an important moderating microclimatic factor that is conducive to successful White Spruce establishment (Chhin and Wang 2002), our study has shown that at a later developmental stage, shade is a contributing factor towards limiting diameter growth. Our results support the hypothesis that there are conflicting habitat requirements for trees at different developmental stages (Schupp 1995). Thus, in the context of future global warming (IPCC 2007) in a climatically sensitive ecotonal region of the aspen parkland, although moderated microclimates may act as micro-scale refugia or "safe sites" (Harper 1977) for tree seedling establishment, this may be at the expense of reduced growth at a later developmental stage. Models of forest growth in response to climate change should therefore take into account the role of conflicting habitat requirements for trees at different developmental stages.

Acknowledgments

This study was funded through a Natural Sciences and Engineering Research Council of Canada (NSERC) Postgraduate Scholarship to S. Chhin, and a research grant from Global Forest to G. G. Wang. We thank Drs. R. Staniforth and J. Tardif for their contributions to the initial research proposal. Thanks also go to K. Ryan, R. Klos, and M. Kreiner for their assistance in the field data collection; and K. Schykulski and H. Hernandez of Manitoba Conservation for their logistical support.

Natural Recolonization of Cultivated Land by Native Prairie Plants and its Enhancement by Removal of Scots Pine, *Pinus sylvestris*

PAUL M. CATLING[1] and BARRY KING[2]

[1] Agriculture and Agri-Food Canada, Environmental Health, Biodiversity, Wm. Saunders Building, Central Experimental Farm, Ottawa, Ontario K1A 0C6 Canada; e-mail: catlingp@agr.gc.ca

Catling, Paul M., and Barry King. 2007. Natural recolonization of cultivated land by native prairie plants and its enhancement by removal of Scots Pine, *Pinus sylvestris*. Canadian Field-Naturalist 121(2): 201-205.

A combination of native and introduced plants colonized abandoned cultivated land with adjacent relict prairie and savanna in the Rice Lake region of southern Ontario. After 71 years, the native colonizers included 86 species found in regional prairie relicts, but much of the area was also colonized by introduced Scots Pine, *Pinus sylvestris*, which apparently spread from an adjacent planting. The pines formed expanding patches of dense growth that excluded other species. Removal of the invasive Scots Pine from a 200 m^2 plot within the abandoned land led to colonization 17 years later by 36 native species characteristic of the prairie, savanna and sand barrens of the region. Included in this group of native prairie colonizers were keystone species such as *Andropogon gerardii*, *Carex siccata*, *Ceanothus americanus*, *Comptonia peregrina* and *Quercus velutina*. Areas where patches of Scots Pine had been allowed to continue growing were either devoid of vegetation or had a sparse understory of introduced species and Poison Ivy (*Rhus radicans*). These observations support the concepts of (1) protecting islands of native dry ground flora which can serve as sources for recolonization and (2) protection of old field and particularly recently cultivated land adjacent to protected native grassland to allow natural restoration. The fact that keystone native species were able to colonize the area from which the introduced Scots Pines had been removed suggests that the pines are aggressive competitors that occupy space to the exclusion of the native species. Scots Pine is thus a driver of ecological change in degraded ecosystems. Management including removal of Scots Pine to support native plant biodiversity is strongly supported.

Key Words: Scots Pine, *Pinus sylvestris*, prairie, sand barren, savanna, recolonization, driver, *Andropogon gerardii*, *Carex siccata*, *Ceanothus americanus*, *Comptonia peregrina*, *Quercus velutina*, Rice Lake, Ontario.

Although information on restoration of prairie vegetation is abundant (e.g., Schramm 1992; Packard and Mutel 1997), information on natural recolonization of prairie flora following human impacts (e.g., Inouye et al. 1987; Rabinowitz and Rapp 1985) is relatively scarce. Despite the lack of information it is often considered a good idea to preserve degraded habitats that have islands of pristine habitat or have adjacent pristine habitats that can serve as sources for natural recolonization. It appears in some cases that invasive alien plants can limit the success of natural recolonization in these circumstances but a lack of information is apparent in this area as well. While some have expressed concern that invasive plant species are one of the leading direct causes of biodiversity loss (e.g., Catling 2005), others have questioned the extent to which introduced species threaten biodiversity (e.g., Davis 2003) and several recent articles have recommended changes in language and attitude in dealing with invasive species problems based to some extent on the need for more accurate information (Gobster 2005; Larson 2005). Recently it has been suggested that invasive plants are the passengers rather than the drivers of ecological change in degraded ecosystems (MacDougal and Turkington 2005). As "drivers" the invasives would compete with native species and may also change the environment to reduce the capability of native species to survive. As "passengers" they are not the limiting factor for native species but just along for the ride. MacDougal and Turkington (2005) suggested that if interactive processes were limiting, then removal of invasive plants should result in a direct increase in native species richness (the "driver" model). On the other hand, if invasive plants are not the limiting factor for native plants, then removal of the invasive plant(s) should have little effect (the "passenger" model).

Although common sense suggests that (1) natural recolonization could occur from pristine nuclei and (2) that invasive alien plants may be either drivers or passengers, the cost of managing natural areas requires stronger evidence. A simple field experiment conducted in the Rice Lake region of eastern Ontario provides information relating to these assumptions. It involves invasive alien Scots Pine (*Pinus sylvestris*) and a potentially diverse savanna, sand barren and prairie flora.

In situations where a native sand barren, prairie or savanna has been replaced by a dense stand of Scots Pine with a completely barren and dark understory (e.g., Catling and Carbyn 2005), it is compelling to think of this invasive as a "driver of ecological change" (Didham et al. 2005). Indeed, Scots Pine is listed as the fifth most significant invasive alien plant of natural habitats in Canada (Catling and Mitrow 2005). However, the present question is whether or not Scots Pine is a driver of ecological change in a degraded ecosystem where the native prairie vegetation has been reduced by other

factors. If following perturbation the native prairie species respond by colonizing an area of previously cultivated ground and they also respond by colonizing a portion of that same ground from which invading Scots Pine is removed, then native prairie plants do naturally recolonize and the introduced pine is a driver of ecological change that is clearly in the way since it is preventing the natural restoration of native flora following the cessation of degrading processes.

Methods

Natural Recolonization

The degraded ecosystem in this experiment originated from an area of sandy soil that was completely utilized for the cultivation of cereal crops and especially potatoes until 1935 when it was abandoned. It is located at 44.1268°N, 77.9839°W in Lot 4, Concession 7, originally Haldimand Twp. but now Alnwick/Haldimand township in Northumberland County, Ontario. The eradication of native flora is confirmed by BK whose family occupied the land, and further by aerial photographs taken in 1929. Cultivation was essentially continuous following settlement in the 1850s, but prior to this the region had been a rolling prairie dominated by prairie grasses with localized Black Oak (*Querus relutina*) Red Pine (*Pinus resinosa*) savanna and sand barren flora (Catling et al. 1992). By 2006 a combination of native species and alien species, including alien Scots Pine, had colonized the previously cultivated field. It had become a semi-open forest with 50-year-old pines, including the Scots Pine, along with the native White Pine (*Pinus strobus*) and both Red (*Querus rubra*) and Black oaks, but throughout the forest were openings of various sizes with a combination of native prairie species (see Table 1) and invasive alien species, including *Hypericum perforatum, Poa compressa, Hieracium pilloselloides, Rumex acetosella, Potentilla norvegica*, and especially *Pinus sylvestris*. Native species that have colonized the abandoned potato field are believed to have spread from the adjacent Russ Creek pioneer cemetery and from the adjacent Barr property preserve, which was never cultivated. The early pioneer graveyard dates from 1849 (earliest marker, although it had a schoolhouse beside it in 1845 and was likely used much earlier) with few burials after 1900. The prairie plant community in pioneer graveyards in prairie regions was usually not cultivated or grazed unlike much of the surrounding landscape because it was sacred ground. Since it was only controlled occasionally with a scythe, the prairie vegetation survived and this seems to be the case with the Russ Creek Cemetery, which is a nucleus of rare and restricted native prairie species. In 2006 an open (treeless) portion of the recolonized field that was 0.8 hectares in extent was selected as a sample plot to document recolonization of native species. All native plant species present in this sample plot were recorded during spring, summer and fall visits in 2006.

Effect of removing Scots Pine

The invading Scots Pines appeared to be preventing the re-colonization of native species in the old field since they grew in dense stands that contained no other species of vascular plants. In 1991 a dense stand of pines was removed from an area of 200 m^2 adjacent to the sample plot to allow colonization of native species. Beneath this stand, and beneath others within 100 m, the only plants at the time of tree removal were occasional depauperate specimens of Poison Ivy (*Rhus radicans*) which does well in the decomposing leaf litter of Scots Pine needles. In 2006 the area from which the trees were removed was surveyed and all native plant species present were recorded during spring, summer and fall visits. Native flora was also recorded from adjacent stands of Scots Pine (where the trees had not been removed).

Scientific and common names used in the text generally follow Kartesz and Meacham (1999). Representative specimens are at the AAFC (Agriculture and Agri-Food Canada) vascular plant herbarium in Ottawa (acronym – DAO).

Results and Discussion

Natural Colonization

In 2006, 71 years after the old potato field was abandoned as cultivated land, a total of 86 species characteristic of natural prairie, savanna and sand barrens in the region was recorded in the 0.8 hectare sample plot of an open (treeless) area (Table 1). It is clear that native species can recolonize seriously degraded habitat in this region but it is evidently a slow process since the occurrence of native species was still very patchy after 71 years despite a relatively uniform substrate and elevation throughout the area. The return of prairie flora to the previously cultivated field is to be expected on the basis of observations elsewhere where dispersal and colonization from adjacent protected sites have proven to be the major factors in old field succession (e.g., Inouye et al. 1987). The results of this study support the concept of protecting islands of native dry ground flora which can serve as sources for recolonization. The results also suggest that even in the northeastern-most prairie and savanna habitats, protection of previously cultivated land adjacent to protected native grassland is likely to result in an old field succession that includes many native prairie species. Furthermore, some studies have shown that the native prairie species increase with time (over 60 years) and with increasing soil nitrogen at the expense of both the introduced plants and native non-prairie plants (Inouye et al. 1987: Figure 8). Thus protection of abandoned farmlands adjacent to protected sites is likely to result in a degree of natural restoration that can be supported through plantings and management.

Effect of Removing Scots Pine

It is likely that the colonization by native species in the old potato field would have been more extensive

TABLE 1. Native species of prairie, savanna and sand barren habitats recorded in 2006 that naturally colonized a 0.8 ha tare plot of previously cultivated land abandoned in 1935. The native species recorded in the 200 m² subplot in 2006 (i.e., 15 years after removal of invading Scots Pines, are indicated with an asterisk (*).

and less patchy if the Scots Pines had not invaded. Scattered dense stands of Scots Pine were without other species in 1991 and in 2006. However, within the recolonized area of the old field where the Scots Pines were removed in 1991, 36 native species of prairie, savanna and sand barren affinity were found in 2006, and had thus colonized this space within 15 years (Table 1). The absence of native species under the dense Scots Pines that remained suggested that this colonization would not have occurred if the pines had not been removed.

Although introduced species had also colonized this area from which the Scots Pines were removed, including particularly *Poa compressa, Hieracium piloselloides* and young Scots Pines, the native species were at least 50% of the cover. Therefore, the pines occupy space to the exclusion of the native species and restrict recolonization of disturbed sites. Since only more pines and Poison Ivy and raspberries *Rubus* spp. occur in the older (more than 50 years old) Scots Pine stands in the region, there is very good evidence that the Scots Pines interfere with the recolonization of native prairie species following cessation of degrading processes and apparently also change the environment to reduce the capability of native species to survive. In adjacent stands of Scots Pines the understory was bare or covered only by a scant growth of Poison Ivy, raspberries, and introduced plants. The native species that responded to the removal of the pines included the characteristic and keystone native species of prairie, savanna and sand barren such as *Andropogon gerardii, Carex siccata, Ceanothus americanus, Comptonia peregrina* and *Quercus velutina*. The fact that these native species were able to colonize the area from which the pines were removed, but did not where the pines remained, suggests that the pines are aggressive competitors that occupy space to the exclusion of the native species and change conditions by competing for nutrients, reducing light and changing soil characteristics with leaf litter accumulation, so that most of the native species of prairie, savanna and sand barren cannot exist. Scots Pine in this situation and evidently in many other situations (e.g., Catling and Carbyn 2005) is thus a driver of ecological change. Management including removal of Scots Pine to support native plant biodiversity is strongly supported. Since the trees are relatively slow growing, slow to mature, reproduce only by seed, are conspicuous at all times, and easily eliminated by pulling and cutting and/or burning, control of Scots Pine is much less problematic than the control of some other invasive plant species.

Conclusion

These observations suggest that natural recolonization by native prairie species can occur, but that it is hindered by invasive alien Scots Pine, which drives ecological change in a degraded prairie ecosystem.

Acknowledgments

Ms. B. Kostiuk provided extensive assistance in the field survey. Earlier surveys in the area were conducted by D. White and E. Heuvel.

A High Elevation Record of the Star-nosed Mole (*Condylura cristata*) in Northeastern Vermont

Ryan W. Norris and C. William Kilpatrick

Department of Biology, University of Vermont, Burlington, Vermont 05405 USA;
e-mail: rnorris@zoo.uvm.edu and wkilpatr@ zoo.uvm.edu

Norris, Ryan W., and C. William Kilpatrick. 2007. A high elevation record of the Star-nosed Mole (*Condylura cristata*) in northeastern Vermont. Canadian Field-Naturalist 121(2): 206-207.

A single male Star-nosed Mole, *Condylura cristata*, was captured in a rock pile at the top of East Mountain (elevation 1042 m; 3240 ft) in northeastern Vermont. Although known from high elevations (up to 1676 m; 5500 ft) in southern U.S. states, this species was not known to occur above 573 m (1880 ft) in the northern part of its range. This record is also important in confirming that *C. cristata* has some climbing ability when travelling above ground.

Key Words: Star-nosed Mole, *Condylura cristata*, elevation, talus, Vermont.

The Star-nosed Mole, *Condylura cristata*, has the largest and most northerly geographic range of all North American moles (Peterson 1966; Hall 1981). The species ranges from southwest Manitoba to Labrador and Nova Scotia, down the eastern United States to South Carolina, and to the Great Lakes region (Petersen and Yates 1980). The species is known to be associated with moist soils near marshes and streams and is an excellent swimmer (Hamilton 1931; Petersen and Yates 1980). Habitat preference for the Star-nosed Mole is usually characterized as low wet ground near bodies of water, swamps, wet meadows, wet spots in fields or low-lying woods, and dry soils within mixed hardwoods near water (Godin 1977; DeGraaf and Yamasaki 2001).

Beane (1995), Laerm et al. (1997), and McCay et al. (1999) have suggested that *C. cristata* is quite common in high elevations in states at the southern edge of its distribution such as North Carolina and South Carolina. Elevational records reported for southern U.S. states include a record at 760 m (2494 ft) in South Carolina (Laerm et al. 1997) and several individuals from the Smoky Mountain National Park at elevations ranging from 488 to 1676 m (1600-5500 ft; Linzey and Linzey 1971). Literature records from Canada and northern U.S. states rarely report elevation, but all available records are lower. The highest elevation reported at northern latitudes that we have been able to find is Saunders's (1988) suggestion that *C. cristata* ranges up to 573 m (1880 ft) in elevation in the Adirondacks of New York.

Study Area and Methods

The summit of East Mountain in northeastern Vermont was modified in 1955 with the construction of the North Concord Air Force Station. The ridgeline was levelled creating an area of approximately 17 acres on the summit for this radar station. The rubble from this modification was pushed to the edges, levelling the surface and creating substantial areas of talus. The station was deactivated in 1963; the buildings have slowly deteriorated, and have been partially dismantled. The native fauna and flora have since recolonized the modified area. Dense regenerative spruce-fir forest now covers much of the summit and small mammals associated with talus habitat, such as the Yellow-nosed Vole (*Microtus chrotorrhinus*), have been found in this human-made talus habitat.

During a small mammal survey, 30 Sherman live traps, baited with rolled oats, were set in and adjacent to one of several human-made talus piles at the top of East Mountain (elevation 1042 m or 3420 ft), East Haven township, Essex County, Vermont, 44°39.5'N 71°46.1'W over three nights (23-25 August 2004). Traps were checked daily and rebaited as needed. The talus pile was approximately 20 m in diameter and contained bare, flattish rocks ranging from ~ 0.5 m to 3 m in diameter. It was located on a gentle slope and had small pools of standing water. No larger streams or bodies of water were observed in the vicinity. Traps in the talus were placed on rocks, not soil, but a small quantity of humus had collected in some areas.

Results

A single male *C. cristata* was discovered dead in a Sherman trap placed among rocks approximately 5 m from the edge of the talus pile on the first night of trapping (23 August). This night saw moderate rain with nighttime low temperatures at or approaching 0°C. The measurements of this specimen are: total

length 174 mm, tail length 80 mm, and hind foot length 27 mm. Skin, skull, and tissue are housed in the Zadock Thompson Natural History Museum at the University of Vermont (catalog number 5273). Other species captured over the course of these three nights of trapping were Short-tailed Shrew, *Blarina brevicauda* (1); Smokey Shrew, *Sorex fumeus* (1), Southern Red-backed Vole, *Myodes gapperi* (5), and Deer Mouse, *Peromyscus maniculatus* (8).

Discussion

The Star-nosed Mole, *Condylura cristata*, is clearly a more northern-adapted species than other moles in eastern North America. The relatively high number of reports of this species in mountainous areas in southern states is not surprising considering its distribution as far north as Labrador. Our capture of the species at a high elevation site in Vermont was unexpected, particularly considering that it was taken in a talus pile and not associated with soil or long-term standing water. The single specimen reported here is evidence that the Star-nosed Mole also occurs at high elevations (at least 1042 m; 3420 ft) even in the northeastern USA. This capture also suggests that they can live, or travel through, rocky areas away from soil. Peterson (1966) suggested that Star-nosed Moles spend more time above ground than other mole species and, as a result, are occasionally found dead on the surface or captured on the surface with snap or live traps.

The capture of the mole amongst rocks and not on bare soil suggests that it must have been maneuvering within this rock pile. Hickman (1982) reported observing a vertical climb of 60 cm by a Star-nosed Mole in the corner of a concrete column, and Schmidt (1931) reported a Star-nosed Mole climbing two feet out of a swimming tank. Our capture provides further indication that *C. cristata* is capable of some degree of climbing, a feature not often attributed to fossorially adapted mammals. Hickman (1982) hypothesized that the climbing ability of *C. cristata* may serve to aid in mobility across rocky areas. Our capture is also consistent with this idea.

Acknowledgments

The authors thank Charles A. Woods for important discussion leading to the preparation of this manuscript. This specimen was collected in association with a small mammal survey funded by the Kingdom Commons Group.

Northern Long-eared Bat, *Myotis septentrionalis* (Chiroptera: Vespertilionidae), on Prince Edward Island: First Records of Occurrence and Over-Wintering

JENNIFER A. BROWN[1], DONALD F. MCALPINE[2], and ROSEMARY CURLEY[3]

Brown, Jennifer. A., Donald F. McAlpine, and Rosemary Curley. 2007. Northern Long-eared Bat, *Myotis septentrionalis* (Chiroptera: Vespertilionidae), on Prince Edward Island: first records of occurrence and over-wintering. Canadian Field-Naturalist 121(2): 208-209.

First occurrence of the Northern Long-eared Bat, *Myotis septentrionalis*, on Prince Edward Island is reported. A mixed-species hibernaculum of *M. septentrionalis* and the Little Brown Bat, *M. lucifugus*, is also described from southeastern Prince Edward Island. This is the first record of bats over-wintering in the province and the first time either species has been reported making use of a building as a hibernaculum.

Key Words: Little Brown Bat, *Myotis lucifugus*, Northern Long-eared Bat, *Myotis septentrionalis*, Prince Edward Island, distribution, hibernaculum.

The bats of Prince Edward Island are poorly known. Although seven species have been recorded from the adjacent mainland of New Brunswick and Nova Scotia (van Zyll de Jong 1985), only the Little Brown Bat (*Myotis lucifugus*) and Hoary Bat (*Lasiurus cinereus*) are known from the Island (van Zyll de Jong 1985; McAlpine et al. 2002). Cameron (1958) reported a sighting which he believed to be a Red Bat (*Lasiurus borealis*) near coastal Fortune Bridge, Kings County, Prince Edward Island (46°21'23"N 62°29'57"W) on 7 June 1954, but this species remains unconfirmed on the Island. Neither have any bat species been documented to hibernate on Prince Edward Island. Here we document the first occurrence of the Northern Long-eared Bat (*Myotis septentrionalis*) from the province and report a mixed-species hibernaculum of *M. lucifugus* and *M. septentrionalis* from southeastern Prince Edward Island.

On 24 September 1988, two bats retrieved by a house cat (*Felis domesticus*) were collected in Breadalbane, Queens County, Prince Edward Island (46°21'23"N 63°29'57"W) by JAB and subsequently identified as *M. septentrionalis*. These specimens, deposited in the Canadian Museum of Nature (CMN), include a male (CMN 52612) and a female (CMN 52613). Measurements for both bats (M (male), TL (total length) 85 mm, T (tail) 37 mm, HF (hind foot) 10 mm; F (female), TL 90 mm, T 36 mm, HF 10 mm) fall within the range for the species presented by van Zyll de Jong (1985).

On or about 10 January 1989 a commercial pest control officer removed about 800 bats, both Little Brown and Northern Long-eared bats, from the basement of a home at Culloden, Queens County, Prince Edward Island (46°0'58"N 62°42'8"W; reported in the media as Murray River, the larger nearby community). All bats were destined to be incinerated. However, DFM was able to secure 781 of these bats alive and an unsuccessful attempt was made to maintain them in a state of torpor over the winter with the intention of spring release. Various media reports suggest that the hibernaculum contained 1500 bats (Anonymous 1989*; Cody 1989 a*, b*; White 1989*). However, communication with the pest control officer (personal communication to DFM) confirmed that all hibernating bats observed were removed. Information presented here is based on an examination of all 781 bats, apparently the contents of virtually the entire hibernaculum. We visited the hibernaculum site on 29 November 1990 and found only two torpid female *M. septentrionalis,* clinging to wooden floor joists. A voucher series of both species from the site have been deposited in the mammal collection of the New Brunswick Museum.

The hibernation site was the unheated basement of an occupied home, built about 1980. The house had been recently re-occupied following a 3-5 year vacancy (resident personal communication to DFM). The basement had an earthen floor and island stone and mortar foundation walls with inside dimensions about 11 × 8 m and a ceiling height of 1-2 m. Entry to the basement was via a trap door on the first floor. Air temperature in the hibernaculum recorded on the night of 29 November 1990 was 11.3°C. This hibernation temperature, while above the mode of 6°C for vespertilionids, falls within the range of -4° to 13°C and 0.6°C to 13.9°C reported for Little Brown and Northern Long-eared bats; respectively (Webb et al. 1996). The hibernaculum was dominated by the Little Brown Bat (82.6%); with smaller numbers of the Northern Long-eared (17.4%). In both species sex ratios were slightly

female biased (62.1% and 57.1% in *M. lucifugus* and *M. septentrionalis*, respectively). We also assessed reproductive status by dissection of all Northern Long-eared Bats following the criteria and terminology of Sluiter and Bouman (1951), Sluiter (1954, 1961), and Racey (1974), with the following results: males; 5.9% sexually immature, 94.1% sexually mature; females; 17.5% nulliparous, 14.2% nonparous, 68.3% parous.

The Northern Long-eared Bat is widespread across Atlantic Canada (van Zyll de Jong 1985). Although less abundant, apparently, in the region than the Little Brown Bat, the presence of the Northern Long-eared Bat on Prince Edward Island is not unexpected. Culloden and Breadalbane are 67 km straight-line distance apart, suggesting *M. septentrionalis* may be widespread in the province. Conversely, the discovery of large numbers of hibernating bats on the Island was unanticipated. The province is underlain largely by Permian sandstones, siltstone and glystone (van de Poll 1983) and we are aware of no natural caves or abandoned mines on the Island that might provide suitable hibernacula. The closest natural caves serving as bat hibernacula occur in adjacent New Brunswick and Nova Scotia (McAlpine 1983; Mosely 2007). Fenton and Barclay (1980) were unable to locate any records of Little Brown Bats hibernating in buildings. Likewise, the Northern Long-eared has previously only been recorded hibernating in caves and mines (van Zyll de Jong 1985). Both these species of *Myotis* may be more flexible in their hibernation requirements than the literature suggests, being able to rapidly exploit suitable artificial hibernacula where present.

Acknowledgments

We are grateful to the late C. G. van Zyll de Jong, both for his encouragement and for confirming the identity of the two bats collected at Breadalbane. We also thank the resident of Culloden who so graciously allowed us access to her home, and Earl Peterson, Maritime Varmint and Rodent Control, for agreeing to make the bats removed from this home available to DFM.

Arboreal Late Summer Courtship Behaviour of Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, in Dartmouth, Nova Scotia, Canada

JOHN GILHEN[1] and ROBERT STRUM[2]

[1] Nova Scotia Museum of Natural History, 1747 Summer Street, Halifax, Nova Scotia B3H 3A6 Canada; e-mail: gilhenja@gov.ns.ca

[2] 325 Prince Albert Road, Dartmouth, Halifax County, Nova Scotia B2Y 1N5 Canada

Gilhen, John, and Robert Strum. 2007. Arboreal late summer courtship behaviour of Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, in Dartmouth, Nova Scotia, Canada. Canadian Field-Naturalist 121(2): 210-211.

We report, for the first time, Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, arboreal, late summer, courtship behaviour in the wild observed 4-5 September 2006.

Key Words: Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, arboreal, late summer, courtship behaviour, Dartmouth, Nova Scotia, Canada.

On the morning of 5 September 2006 Robert Strum reported to John Gilhen that a ball of snakes had gathered on a Rhododendron shrub, *Rhododendron* sp., in his yard at 325 Prince Albert Road, Dartmouth, Nova Scotia. In the afternoon of the previous day, 4 September 2006, Robert Strum could see, from the kitchen window, that a number of brown snakes had gathered inside a gazebo style bird feeder on the Rhododendron shrub and he was successful in moving them out. The following morning, 5 September 2006, he noticed the snakes had gathered, again, on a branch near the bird feeder, about two meters above the ground (Cover). Upon investigation it was determined that there were four (three males and one female) Maritime Garter Snakes, *Thamnophis sirtalis pallidulus*, involved in courtship behaviour: male number 1, the largest male; males 2 and 3 about equal total length; and 1 female (the largest of the four snakes). The weather at 1200 hours on 5 September 2006 was cloudy and overcast with ambient air temperature of 20°C and temperature near the ground was also 20°C.

At 1215 hours the males were observed moving alongside and over the back of the female. At the same time the body of male number 1 was pulsating rhythmically. This male rubbed his chin along the sides of the female. At this time the tail and about one half of the female's posterior trunk (about 20 cm) drooped downward from one of the supporting branches, with the tails of all three males wrapped around her tail. While the female's posterior body and tail were dangling down, the most active male (male number 1) appeared to maintain ventral apposition to copulate with her (Figure 1).

All four snakes remained on the Rhododendron shrub from the morning to early afternoon but dispersed at some time late in the afternoon, as they were not seen there again that evening or in the following days. It is not known if copulation occurred over the two-day period these snakes occupied the Rhododendron shrub. One of the two subordinate males was collected as a voucher specimen (NSM55388).

Courtship behaviour of the Maritime Garter Snake in captivity has been previously observed by John Gilhen in late August (unpublished). On two separate occasions (August 2001 and August 2004), days after individual females had given birth, two males were observed following alongside the female and trying to attain cloacal apposition. Although other adult females were present in the enclosure, the males were only interested in courting with a recently spent female. These observations of captives and the present observation in the wild suggests that the Maritime Garter Snake mates in late summer, sometime after females give birth, but prior to hibernation.

Galbraith (2001) reports similar arboreal late summer courtship by Eastern Garter Snakes, *Thamnophis sirtalis sirtalis*. Cook (1984) mentions snakes in the genus *Thamnophis* most frequently copulate in spring but have occasionally been noted to copulate in late fall, immediately prior to entering hibernacula. Arboreal spring breeding activity of the Red-sided Garter Snake, *Thamnophis sirtalis parietalis*, was observed on 8 May 1972 near Inwood, Manitoba (Gregory 1975).

Rossman et al. (1996) and Ernst and Ernst (2003) agree mating of *Thamnophis sirtalis* usually occurs in spring after emergence from hibernation but may also take place in autumn. Rossman et al. (1996) also states that, until recently, most of the studies of mating behavior and the factors that regulate the timing of reproduction in *T. sirtalis* have focused primarily if not exclusively on spring activities. Previous accounts of the species in Nova Scotia (Barnes et al. 2006; Gilhen 1984, 2000), have not noted fall mating.

The urbanization of both Halifax and Dartmouth cities over the past two decades has been extensive leaving many isolated pockets of amphibians and reptiles. The Maritime Garter Snakes at the observation site in Dartmouth continue to survive in small numbers in a back yard landscape, surrounded by apartment buildings on the south side, a major city road on the north side and other homes on the east and west sides. Galbraith's (2001) observation of the Eastern Garter

FIGURE 1. An adult male Maritime Garter Snake, *Thamnophis sirtalis pallidulus*, seeking ventral apposition with adult female in courtship behavior on the branches of a Rhododendron shrub at 325 Prince Albert Road, Dartmouth, Nova Scotia, on 5 September 2006.

Snake also took place on private land in a cottage community on the coast sand dune area of the eastern shore of Lake Huron in Ontario.

In Nova Scotia, the Maritime Garter Snake is most common along the shores of lakes, ponds and streams but has readily adapted to a host of urban habitats. Robert Strum has commonly observed Maritime Garter Snakes in his yard and has noted they move down along the base of the swimming pool and probably hibernate under the pool.

Human-assisted Movements of Raccoons, *Procyon lotor,* and Opossums, *Didelphis virginiana*, between the United States and Canada

Rosatte, Rick, Dennis Donovan, Mike Allan, Laura Bruce, and Chris Davies. 2007. Human-assisted Movements of Raccoons, *Procyon lotor*, and Opossums, *Didelphis virginiana*, between the United States and Canada. Canadian Field-Naturalist 121(2): 212-213.

Movements of Raccoons (*Procyon lotor*) ($\bar{x}$ = 479 km) and Opossums (*Didelphis virginiana*) ($\bar{x}$ = 688 km) by means of transport trailers and a train from the USA and Quebec into Ontario were significantly greater than Raccoon movements ($\bar{x}$ = 15 km) from Ontario to New York State determined by mark-recapture. Human-assisted movements of wildlife could have significant impacts with respect to cross-border movements of diseases such as rabies. Proactive communication programs, especially at International border crossing areas, should be encouraged to decrease the occurrence of the unintentional movement of wildlife and associated diseases.

Key Words: *Didelphis virginiana,* Opossum, *Procyon lotor*, Raccoon, movement, disease, rabies, Ontario.

The movement of wildlife and domestic animals by humans has resulted in the national, international, and sometimes global movement of diseases such as rabies, West Nile virus, bovine tuberculosis, parvovirus, chronic wasting disease (CWD), and bovine spongiform encephalopathy (BSE) (Jenkins and Winkler 1987; Nielson and Brown 1988; Woodford and Rossiter 1993; Williams and Barker 2001). The international movement of Raccoons (*Procyon lotor*) from the United States to Ontario, Canada, has been documented previously (Rosatte et al. 1997, 2001); however, those publications did not document the distances moved or geographic areas involved.

During January 1997 and December 2005, a total of 14 Raccoons were documented as having moved across the St. Lawrence and Niagara Rivers from Ontario, Canada, to New York State. Those Raccoons were eartagged and released in Ontario as part of a wildlife rabies control program during 1997-2005 (Rosatte et al. 1997, 2001). They were later recaptured or found dead in the vicinity of Buffalo or Ogdensburg, New York (Figure 1). Exact locations were known for 13 of those. Mean movement of the 13 Raccoons was 15 km (SD=9.0) (range = 3-30 km). The sex and age were known for 11 of the 13 Raccoons. More adult males (9) than adult females (2) moved from Ontario to New York (Chi Square = 8.9; $P<0.0028$). Mean movement (18 km, SD=8.4) (range = 6-30 km) of adult male Raccoons was greater than mean movement of adult females (7.5 km, SD=6.4) (range=3-12 km) (t=1.65; $P=0.13$).

In addition, during 1998-2005, a total of 14 Raccoons and two Opossums (*Didelphis virginiana*) were found in transport trailers and in a box car on a train in the greater Toronto area. The point of departure of those vehicles included Ohio, Illinois, Tennessee, New York, Michigan, Quebec, and Ontario (Figure 1). In most cases the trailer or container was locked and sealed at the point of departure and was not opened until it arrived in Ontario. Mean movement of Raccoons by vehicle from the USA and Quebec (n=11) to Ontario, Canada, was 479 km (SD=250) (range=250-890 km). This was significantly greater (t=6.9, $P<0.00002$) than movements of Raccoons noted above that did not involve transport via vehicles. The two Opossums moved 1000 km from Tennessee and 376 km from Michigan, respectively.

In Ontario, rabid Raccoons have been documented as having moved 0.7-4.1 km (Rosatte et al. 2005, 2006). Median movements of non-rabid Raccoons in Ontario were generally less than 1 km, with movements rarely exceeding 50 km in distance (Rosatte 2000; Rosatte et al. 2006). However, those movements were assumed not to have been due to human involvement (intentional or otherwise) (i.e. by vehicles). The exceptional movements for Raccoons, as well as Opossums, documented in this paper, indicate that those species have the potential to move infectious diseases such as rabies significant distances. In view of this, people should be vigilant for wildlife such as Raccoons riding on vehicles. Transport trailer drivers (as well as operators of other vehicles such as ferries, trains, boats) should be encouraged to check their vehicles and trailers for wildlife prior to departure to minimize the unintentional movement of animals. This will assist in decreasing the movement of wildlife diseases. Signage at international border crossing areas advising drivers to check their vehicles for wildlife should also be posted. These tactics were used during the 1990s in Ontario in an attempt to prevent the movement of Raccoon rabies from the United States to Canada (Rosatte et al. 1997).

Correlation Between Age Estimates for Elk, *Cervus Elaphus*, Using Tooth Wear/Eruption Patterns and Counts of Annuli in Tooth Cementum

Rosatte, Rick, Andrew Silver, Mark Gibson, Bruce Chisholm, and Norm Cool. 2007. Correlation between age estimates for Elk, *Cervus elaphus*, using tooth wear/eruption patterns and annuli in tooth cementum. Canadian Field-Naturalist 121(2): 214-215.

Two different techniques, (1) tooth wear, tooth eruption patterns and other attributes and (2) counting annuli and seasonal growth zones in the cementum of incisor teeth, were used to estimate the age of Elk, *Cervus elaphus*, that were relocated from Alberta to Ontario, Canada. Age estimates for Elk ranged from 2 to 20 years, and a significant relationship was found between the ages acquired by the two methods. Critical to acquiring accurate age estimates for Elk were staff with extensive skill with respect to the aging technique utilized.

Key Words: Elk, *Cervus elaphus*, age estimates, annuli, cementum, tooth wear.

During 1998-2001, 443 Elk (*Cervus elaphus*) were acquired from Elk Island National Park (EINP), Alberta, Canada, and released in four different areas of Ontario, Canada (Rosatte et al. 2002; Rosatte et al. 2007). Elk were aged according to tooth wear, eruption patterns (deciduous and permanent teeth), colouring and staining of teeth, as well as by comparison to a reference sample of known-age Elk jaws, during processing at EINP (Hudson et al. 2002) (Figure 1). By about two years of age the upper pair of permanent incisiform canines erupt (the ivory) and by about 3 years of age, the 4 pairs of permanent incisors have erupted. The weight of the animal was also considered when estimating the age of Elk at EINP; e.g., the weight of 7-month-old calves, 1½-year-old, and ≥ 2½-year-old Elk was approximately 100-120 kg, 130-170 kg, and > 180 kg (± 10 kg), respectively. The weights of the Elk were checked following age estimation to ensure that the age estimate fell into the above age/weight categories.

During 1999-2004, incisor teeth were collected opportunistically from Elk that died in Ontario post-release. These teeth were aged via counting annuli and seasonal growth zones in tooth cementum (Figure 2). The annuli or rings in the cementum represent yearly growth. By counting the number of annuli in the cementum an estimate of the animals age can be determined (Johnston et al. 1999). The age estimates were compared with those obtained during processing at EINP after the tooth wear age estimates were extrapolated to coincide with the time of death of the Elk in Ontario. Staff involved in aging had many years of experience with the aging technique.

Incisor teeth were extracted (via tooth extractors) from a sample (n = 10) of Elk that died in Ontario post-release. Two yearling bulls, for which the age was known, served as controls. Teeth were cleaned of tissue and soaked in 70% ethanol for 5 minutes to prevent the transmission of infectious pathogens. They were then preserved in 10% formalin or frozen at -20°C. Teeth were sectioned using an Isomet double-bladed saw (Buehler Isomet, Techmet, Scarborough, Ontario) according to Johnston et al. (1999). Each section (60-100μ) was mounted on a microscope slide with Per-

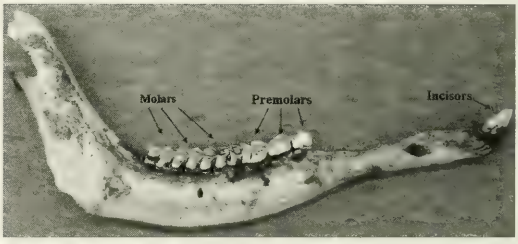

FIGURE 1. Photo of an Elk (*Cervus elaphus*) mandible showing incisor, premolar, and molar teeth.

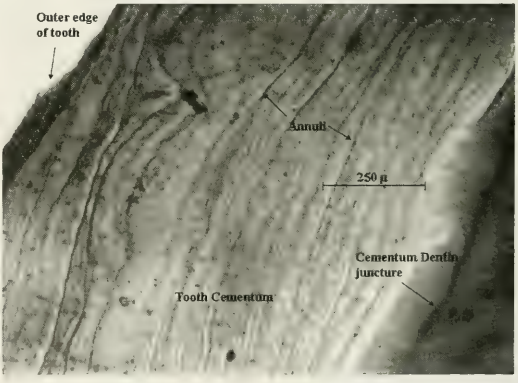

FIGURE 2. Longitudinal section (decalcified, Harris modified hematoxylin stain using bright field illumination) of an incisor tooth (100× magnification) from an Elk (*Cervus elaphus*) depicting annual growth lines (annuli) in the cementum. Estimated age is 20 years.

mount and covered with a cover slip. Two microscopic techniques were used to determine an age estimate for each incisor. To distinguish juveniles from adults, the undecalcified, unstained sections were viewed under a compound light microscope (50× and 100× magnification) using polarized light to view seasonal grow zones. In the majority of sections (especially older animals), the annuli were not distinct and not easily discerned under polarized light. These were decalcified (according to Johnston et al. 1999), stained (Harris modified hematoxylin), and placed in 70% ethanol for 2-3 minutes. Slides were then air-dried, covered with Permount and a cover slip, and examined under the microscope (unpolarized light) to count the number of annuli to obtain an estimate of age (Johnston et al. 1999) (Figure 2).

Age estimates for Elk acquired by tooth wear (and other indicators as noted above) and annuli or seasonal growth zone counts in incisor teeth, ranged between 2 and 20 years of age (Figure 3). The first week of June was used as the birth date for Elk (Hudson et al. 2002). A simple linear correlation and a t statistic (Zar 1974) were used (Statistica 6.0 software, StatSoft, Tulsa, Oklahoma, USA) to measure the relationship and level of significance between tooth wear and counting annuli for age determination in Elk. The correlation was found to be significant ($P < 0.0001$; $t = 20.1$; $r = 0.9903$; $r^2 = 0.98$). There was a positive slope of 1.09 between the ages acquired by the two methods ($Y = 1.0918 x = 1.261$) (Figure 3).

This study examined the relationship between two methods used to estimate the ages of wild Elk. Tooth wear estimates of age may be inexact as tooth wear could be affected by diet, soil type and substrate (Hudson et al. 2002). However, as the Elk at EINP were in an enclosed (fenced) situation, these variables were fairly constant as their geographical location remained unchanged among years. Therefore, we believe the age estimates acquired by tooth wear (and other attributes that were examined) were fairly accurate. Some authors (Keiss 1969; Hamlin et al. 2000; Hudson et al. 2002) suggest that staining sections of teeth and counting annuli provides the most reliable estimate of age for Elk. Furthermore, Keiss (1969) and Hamlin et al. (2000) only found about a 50% agreement between tooth eruption/wear and cementum annuli counts and concluded that wear/eruption estimates are unreliable for aging Elk. On the contrary, in our study, although the sample size was small, age estimates for Elk obtained by tooth wear correlated well with those acquired by counting annuli in stained and unstained sections of incisor teeth. We believe that the different result in this study was due to staff expertise with both aging techniques and that this is critical to obtaining accurate age estimates for Elk.

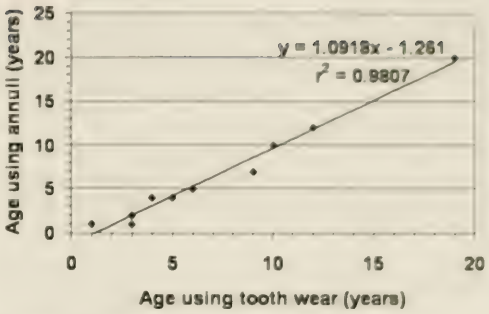

FIGURE 3. Relationship between age of Elk (*Cervus elaphus*) determined by tooth wear and annual growth lines (annuli) in tooth cementum ($n = 10$).

Acknowledgments

The Ontario Elk restoration and research program is supported by the Ontario Ministry of Natural Resources (OMNR), Wildlife Research and Development Section, Dr. J. Chris Davies, manager, and the OMNR, Wildlife Section, Deb Stetson, manager. Special acknowledgment goes to the staff of the OMNR, Rabies Research and Development Unit, Peterborough, Ontario, to Trent University graduate students, Peterborough, Ontario, to the Canadian Food Inspection Agency, Edmonton, Alberta, and to Parks Canada, EINP, Alberta (especially Rob Kaye), who assisted with the acquisition of teeth for aging and/or the processing of elk at EINP. The manuscript was reviewed by Dr. J. Chris Davies, B. Stevenson, and P. Bachmann, OMNR.

Predator-Prey Interaction Between an American Robin, *Turdus migratorius*, and a Five-lined Skink, *Eumeces fasciatus*

E. NATASHA VANDERHOFF[1, 2]

[1]Department of Biology, University of Louisville, Louisville, Kentucky 40292 USA
[2]Current address: Department of Biology, Francis Marion University, Florence, South Carolina 29501 USA; e-mail: evanderhoff@fmarion.edu

Vanderhoff, E. Natasha. 2007. Predator-prey Interaction between an American Robin, *Turdus migratorius*, and a Five-lined Skink, *Eumeces fasciatus*. Canadian Field-Naturalist 121(2): 216-218.

I observed a predator-prey interaction between a juvenile American Robin (*Turdus migratorius* L.) and a juvenile Five-lined Skink (*Eumeces fasciatus* L.). Although Robins are considered omnivorous, there are no previous reports of a robin eating lizards although they have been recorded as occasionally taking snakes. I discuss the age of the individuals involved as it relates to prey capture and escape.

Key Words: American Robin, *Turdus migratorius*, Five-lined Skink, *Eumeces fasciatus*, predation.

The American Robin (*Turdus migratorius* Linnaeus) and Five-lined Skink (*Eumeces fasciatus* Linnaeus) are commonly found in deciduous forests, as well as rural and urban areas and parks, in eastern North America. However, although they inhabit the same areas, there have been no accounts of predator-prey interactions between these two species. The American Robin, the most common thrush species in North America, is a versatile forager, feeding largely on invertebrates during the spring and summer and shifting to a diet with more fruits in the fall and winter (Sallabanks and James 1999; Wheelwright 1986). Robins also occasionally consume vertebrate prey, including snakes (Davis 1969; Netting 1969; Richmond 1975; Erickson 1978), shrews (Powers 1973), and even fish (Bayer 1980; Kimball 1944). However, there are no published records of Robins pursuing or consuming any species of lizard (Sallabanks and James 1999).

The Five-lined Skink is a small lizard associated with forest openings throughout the eastern United States and southern Ontario (Fitch 1954; Behler and King 1997). Juveniles and adults differ in their appearance; adults develop a solid brownish color, whereas juveniles have five light-colored stripes on a black body and a bright blue tail (Behler and King 1997). Juveniles can lose their blue tail (autotomy) during interactions with predators. This, along with their striped pattern, is thought to confuse predators and allow the skink to escape (Fitch 1954; Clark and Hall 1970; Vitt and Cooper 1986; Goodman 2006). Numerous mammalian and reptilian predators of the Five-lined Skink have been documented (Fitch 1954). Although several birds, including mimids, icterids, corvids, and accipiters, prey upon lizards (Cooper and Vitt 1985), the American Robin has not been known to prey upon lizards. Additionally, there have only been a few confirmed avian predators of the Five-lined Skink, including the American Kestrel (*Falco sparverius*) (Heintzelman 1964), Broad-winged Hawk (*Buteo platypterus*) (Fitch 1974), Cooper's Hawk (*Accipiter cooperii*) (Toland 1985), Greater Roadrunner (*Geococcyx californianus*) (Brown 1963) and Red-shouldered Hawk (*Buteo lineatus*) (Fitch et al. 1946).

I observed a predator-prey interaction between an American Robin and a Five-lined Skink on 24 August 2006 at Joe Creason Park in Jefferson County, Kentucky (38°12'N 85°42'W). The interaction took place in a field at the edge of a forested area and I used 10 × 43 binoculars to aid my observations. The initial observations of two juvenile robins (J1 and J2), and the juvenile skink were made from a distance of over 20 m. Subsequent observations of J2 were made from about 10 m. At 18:18 I observed J1 with a skink in its beak. At 18:19 J2 approached J1, at which point the skink escaped by jumping out of J1's beak. The robins pursued the skink for approximately 30 cm; J2 captured the skink and carried it approximately 5 m away while J1 flew off. I moved closer and observed the robin handle and consume the skink over the next six minutes. The robin, holding the skink in its beak, beat the skink on the ground multiple times and then took several bites. The robin repeated this four times, stopping periodically to stand alert and scan the area. The robin also took one large bite and swallowed a large portion of the skink. After the robin flew off, I examined the spot and found only the skink's entrails. Closer examination of the site where the skink was initially captured revealed the skink's blue tail. Although I was unable to measure the skink, based on the tail remnant and entrails the skink was approximately 90 mm.

This is the first account of a predator-prey interaction between the American Robin and the Five-lined Skink. The Five-lined Skink spends most of its time under cover such as woody debris and thus may largely avoid predation from avian foragers (Fitch 1954). However, the ranges and habitat of both species overlap, and it is likely that skinks may occasionally be pursued and successfully captured by robins. At least one other thrush species is known to consume skinks; *Turdus caleanops* of Japan has been recorded to prey upon juvenile *Eumeces okadae* (Hasegawa 1990). It is interesting that the interaction I observed took place

between juveniles of both species. Previous studies have shown that juvenile robins are less skilled when foraging for invertebrates and fruits (Vanderhoff and Eason 2007). Therefore, one might not expect that a juvenile robin would attempt to capture a skink. However, juveniles are often more likely than adults to pursue and consume novel food items (Wunderle 1991).

Juvenile Five-Lined Skinks may also be less skilled at escaping predators than are adults. I did not witness the initial capture of the skink by J1 so I am unsure of any anti-predator behaviors that the skink may have used at that time. However, many species of *Eumeces* flicker their vividly colored tails to distract predators (Cooper 1998), and studies have shown that juveniles that display this behavior are better able to escape from snakes (Cooper and Vitt 1985).

Five-lined Skink populations may be more intermittent and less common in Ontario than in Kentucky where this interaction was observed. In recent years Five-lined Skink populations have been in decline in Canada, and under the Species at Risk Act the Five-lined Skink is listed as a species of special concern (Quirt et al. 2006). Human removal of woody debris has eliminated an important microhabitat for the skink, and the decline in appropriate microhabitat is thought to be one of the main causes for the skink's decline in some areas of Canada (Hecnar and M'Closkey 1998). Woody debris is important for nest sites, but also acts as an important refuge from predators (Hecnar 1994), and removal of these refuges may increase the Five-lined Skinks' encounter rate with avian predators, like the American Robin, as well as increase the skinks' likelihood of being captured.

Birds and lizards are commonly studied organisms, but documentation of predator-prey interactions between these two groups is rare (Blomberg and Shine 2000), although avian predation is thought to be the selective pressure responsible for the vivid blue tail of juvenile skinks (Cooper and Vitt 1985), little information exists on interactions between birds and skinks. Both quantitative and qualitative information on predator-prey interactions between birds and lizards is needed to add to knowledge of both groups.

Acknowledgments

I thank Catherine Byers, Chadwick Hanna, Lina Rifai, my advisor Perri Eason, and two reviewers for helpful comments on the manuscript. I also thank Louisville Metro Parks for allowing me to conduct my research at Joe Creason Park.

Book Reviews

Book Review Editor's Note: From this issue forward we will use the current currency codes. Thus Canadian dollars are CAD, U.S. dollars are USD, Euros are EUR, China Yuan Renmibi are CNY, Australian dollars are AUD, and so on. You will find these are the codes now used by financial institutions and internet currency converters. I will include an updated note for the next few issues as a reminder.

ZOOLOGY

Atlas of Breeding Birds of Ontario 2001 – 2005

By M. D. Cadman, D. A. Sutherland, G. G. Beck, D. Lepage, A. R. Couturier. 2008. Published by Bird Studies Canada, Environment Canada, Ontario Field Ornithologists, Ontario Ministry of Natural Resources, Ontario Nature. xxii + 706 pages. 96.00 CAD Cloth.

There's nothing like a good, hefty book to make reading in bed difficult; there's also nothing like a good, hefty book that's full of all the information it's supposed to have. This second atlas of Ontario birds is both. Like all recent atlases, this book has enough coffee-table appeal to be of interest to non-birders, and could in fact, entice them into the fold. This is not at the expense of the data, since the book typically presents the data thoroughly and well. I am very happy that Ontario (as most jurisdictions) chose to publish a book, and not a CD-ROM, as did Oregon…people will always be able to read books…CDs may already be on their way out.

Given that this is a second atlas for Ontario, the opportunity to compare results with the first atlas was there, and was used. The reader can see instantaneously whether 10 × 10 km squares (in southern Ontario) or 100 × 100 km blocks (in northern Ontario) have had a change in breeding status. This segues me to describe the regrettable, but unfortunately practical practice of giving less detail to the north than the south; being a native born-and-raised northern Ontario boy…this has always bothered me, but as stated, I see the practicality. What I don't understand, though, is the situation where the distribution of a bird like the Palm Warbler is shown as six squares on a large, and large scale southern Ontario map, even though the distribution of 99% of the population is shown on a smaller, and smaller scale, northern Ontario map. At least northern Ontario is covered, unlike the otherwise-fantastic Quebec atlas, which didn't attempt to describe birds in the northern two-thirds of that province.

This atlas has several important chapters of preamble, though, like the Alberta atlas, these are essentially limited to what is necessary to best understand the species accounts. Other jurisdictions have provided a greater diversity of introductory chapters to create an even more useful atlas – these include chapters on the local history of birding and ornithology, aboriginals and their relationships with birds, conservation, and others. Although not necessary, chapters like these would have enhanced the Ontario atlas.

Somewhere in the fleet of introductory chapters or appendices, one would have expected to come across a very basic piece of information – the number of squares in Ontario. There are tables in the introductory chapters and appendices which tell you the number of squares in which a species was found…obviously, without knowing the total number of squares, the former information is less valuable than it could be.

As with the Alberta atlas, each species account is given one double-page spread. This is convenient for the reader and allows for enough text, graphs and maps in most cases. It must have been an editorial decision to do this – surely some species could have done with three pages, without getting verbose. However, a two-page allotment does give a decent treatment to all. The accounts are divvied into appropriate subheadings in Distribution and Population Status, Breeding Biology and Abundance. A multitude of authors wrote these species accounts, and even so, I didn't find a single one lacking. All were well, to me extremely well, written – congratulations go to the authors, reviewers and editors of the species accounts. By using the multi-author approach, the workload is spread out and the project takes advantage of the areas in which these folks specialize.

This atlas incorporated point counts into its methodology as an important way to quantify many species. Very intuitive maps show the distribution of different population densities. By doing this, the third atlas will be better able to quantify population changes on the whole, as well as shifts in population centres and borders within Ontario.

In contrast, there are many other surveys from which information could have been incorporated into the atlas; not all species are effectively sampled using point counts. For example, the Ontario Nocturnal Owl Survey data could have been summarized for each of Ontario's owls; this would not have been a daunting task. The Breeding Bird Survey data, along with the

data from other sources, were incorporated into the Oregon BBA, to the overall benefit of atlas users.

There are some technical points to the data presentation that I did not find appealing or useful, though I will only mention the bigger ones here. For each species, there is a histogram which illustrates the probability that a person spending 20 h birding will encounter a species in a square from one of the five biogeographic regions of Ontario (and another bar illustrating the data for all of Ontario). On the y-axis are the labels for the five regions and the whole of Ontario; the x-axis shows the probability. There are two bars for each region, one for the first atlas, one for the second. Having both bars does give the reader a good idea of the change in abundance of the species. However, there are two issues with these histograms. The first is that the exact value of the probability is put at the end of each of the twelve bars...isn't that what the x-axis is for? For those very few people who need to know an exact value (e.g., a 59.9% chance of finding a House Finch in Lake Simcoe-Rideau) instead of the ballpark x-axis value of 60%, those data can be retrieved from the atlas project. For the rest of us, the data labels (made popular by many software packages) are simply so much clutter.

Secondly, regardless of the data, the x-axis is always calibrated in 20% increments, from 0-100%. That means, for species like the Ruddy Duck and Wilson's Phalarope, where eight of the twelve bars are at 1% or less, the reader barely sees the bars...why not scale the axis from 0-10% to show the data more effectively? This becomes ridiculous with birds like the Worm-eating Warbler and Northern Wheatear, which have some of the six categories blank, and *all* of the others with non-existent bars labelled at 0.0%.

Each of the species accounts features one photograph of the bird and sometimes a habitat and nest shot as well. The quality was from good to great... there were a few shots that I would have replaced, but nothing serious here. To increase the visual appeal, I would have included more habitat shots; both *The Birds of British Columbia* and *Birds of the Yukon Territory* had more of this, and I think that added quite a bit to those books [Neither of those books are atlases *per se*, but both do show distribution and breeding records]. A few photographers contributed many of the pictures, though overall there was a good diversity of photographers; that many peoples' works get featured is always good to see in a volunteer effort...so this is definitely a plus in my mind.

Finally, the cover photo. A Prairie Warbler? Really? Why? This bird was recorded in only 45 squares in Ontario — that's less than 0.5% of the total. If I were to ask you to name the best-known bird of the Yukon, what would it be? And yes, it's on the cover of their book. The widely-dispersed Red-tailed Hawk was a fine choice for the cover of the first atlas of Maritime birds. Surely something much more widespread and charismatic like their provincial bird, or one known to almost anyone who feeds birds in Ontario, like the Dark-eyed Junco, would have been more appropriate. The decision to have the very local Prairie Warbler as the coverbird just boggles my mind.

Overall my impression is that this is quite a good book that could have so easily become a great book. Ontario atlassers should be very satisfied with their second atlas – it largely presents the efforts of their long hours well; users of this book will be faced with a lot of information that is well-organized, and pleasing to read.

The Return of Caribou to Ungava

A. T. Bergerud, Stuart N. Luttich, and Lodewiih Camps. 2007. McGill-Queen's University Press, Montreal, Quebec. 2007. 586 pages. 49.95 CAD Cloth.

This is the most comprehensive book on Caribou ecology and predator-prey relationships that has appeared in many years, perhaps ever. Not only is the research seminal, but the authors systematically dismantle paradigms that have been in vogue for years. According to the authors, Caribou biologists have wasted the last 50 years measuring lichens on winter ranges, when they should have been documenting plant production on summer ranges. Wolves, along with human hunters, both limit and regulate caribou populations, not habitat. Food on the summer range only regulates at high densities and only after the range has been overgrazed. Wolves are driving Woodland and Mountain Caribou to extinction. Caribou populations where Wolves are absent maintain densities 100 times

greater than predated herds. The reason arctic Caribou migrate to barren ground calving areas is to avoid Wolves tied to den sites at treeline. Even so, if it were not for periodic rabies epidemics, migratory Caribou populations would be severely limited by Wolf predation. Volcanic eruptions half a world away trigger population declines in arctic Caribou at high densities. And this is just for starters.

The book chronicles the history of the George River Caribou in Labrador and Quebec from near extinction during the early 1900s to an estimated 600 000 animals before the herd declined. The authors explore the various hypotheses that have been proposed to explain these fluctuations and present data set after data set to separate between competing explanations. In addition, the authors discuss virtually every other Caribou population that has been studied in North America, Scandinavia, and beyond, including the difference between migratory and sedentary herds, which is key to understanding this species' ecology.

To the south of Ungava are small non-migratory populations of Woodland Caribou that are being driven to extinction by Wolf predation. But in reality, Moose and White-tail Deer are to blame. Historically, these areas sustained low-density, widely-spaced Caribou that in and of themselves could support few or no Wolves. Moose and whitetails were absent. But since the early 1900's, Moose and whitetails have extended their range providing alternative prey for Wolves, where none existed before. The Wolves then drive the more vulnerable Caribou ever downward. That is to say, the addition of alternative prey did not buffer predation on Caribou, but instead increased predation pressure, contrary to what many people would expect. But that is not the most intriguing part.

Why were Moose and whitetails absent historically and prehistorically? The authors contend that logging changed coniferous forests to secondary deciduous species favored by Moose and whitetails. In this I believe they erred because fire history data indicate there was always a strong deciduous component in those forests. Besides, Moose and Whitetails can survive on a winter diet of Balsam Fir, as they do on Isle Royale and Anticosti Island. Instead, I believe that native hunters once kept eastern Moose populations in check, as I know native hunters did in western North America, where there are more Moose today than at any time in the last 12 000 years (see *Alces* 33:141-164). Historically and prehistorically, native hunters extirpated Moose over large areas because, like the Wolves discussed above, humans had a multitude of alternative prey, including vegetal resources and fish unavailable to carnivores. As aboriginal hunting pressure declines, prey populations increase. In fact, the authors note that the influenza epidemic of 1918 decimated native populations on Ungava, which in turn allowed Caribou to increase.

I certainly commend the authors for presenting data on aboriginal peoples since the time Ungava was first inhabited and for describing how human hunting impacts Caribou. Most other studies of ungulate ecology begin with the premise that native people are irrelevant because everything was a "wilderness" untouched by the hand of man prior to the arrival of Europeans; e.g., see *The Kruger Experience*. As I have explained elsewhere, however, this is a fatal error. The authors did not make that mistake, but I would suggest they need to look deeper into human evolutionary ecology. Take the seemingly random movements of Caribou, a subject covered at length in this book.

Unfortunately, the authors neglected to consult Binford's data on Inuit Caribou hunters — see *Numamint Ethnoarchaeology*. One of the questions Binford asked was how do caribou hunters select a direction to hunt when they have no prior knowledge of where the Caribou are? The Inuit base their decisions on what we in the West would call mysticism. By careful observation, however, Binford determined that Inuit pre-hunt behavior was simply a random number generator. That is to say, in these cases, the Inuit hunted randomly, which makes perfect ecological sense, odd though it may seem.

If the Caribou moved in a predictable pattern, they would be easy prey for aboriginal hunters, as the authors note when the Ungava herd is forced by topography to cross the George River at Indian House Lake. If the hunters hunted in a predictable pattern, the Caribou would quickly learn to avoid the hunters, and the people would starve. The solution to the Caribou's problem is to move as randomly as possible, while the solution to the hunter's predicament is to hunt randomly. This co-evolution occurred over thousands of years and probably is the only evolutionary stable strategy available to both Caribou and humans and then only because the Caribou's range was vast and diverse. The authors note that even when Ungava Caribou numbered only 15 000 animals, spread over an immense area, aboriginal hunting alone kept the herd from increasing. Using dog sleds, native hunters would follow caribou tracks for days, until the animals were killed or the trail lost.

The *Return of Caribou to Ungava* should be read by everyone with even a passing interest in northern ecology, caribou management, or predator-prey relationships. It should also be read by historians, anthropologists, and archaeologists.

CHARLES E. KAY

Utah State University, Logan, Utah 84322-0725 USA

A Guide to the Mammals of China

Edited by A. Smith and Y. Xie. 2008. Princeton University Press 41, William Street, Princeton, New Jersey USA 08540-5237. 576 pages. 60.00 USD Cloth.

China, like many other areas outside North America and Europe, has had good field guides to the birds for some years. Finally it now has a decent guide to the mammals. Unlike the mammal guides for Africa and South America, this new Chinese book includes a more thorough coverage of the small stuff, such as rodents, pikas, shrews and the like.

It was produced with contributions from nine people from the United States, the United Kingdom, Italy, and China. It is refreshing to see such a cooperative effort by a multi-national team in a region where politics often clash. The book covers all of China, including Taiwan and Xizang [Tibet].

The artwork is by Federico Gemma of Italy and is top quality. I am particularly impressed by the way he has occasionally moved away from the "classic" guide poses. For example, he portrays Tibetan Gazelle leaping through the air. This accentuates the gracefulness of this lovely species. At first it may appear that Gemma has an easy job because so little is known of Chinese mammals in the west. This is not true. We are familiar with the cute poster mammals — the Giant and Red pandas and the Tiger. Many animals are familiar zoo and park species — Muntjac [Red], Sika and Sambar Deer. Others are common species in more accessible places — Ermine, Caribou, Moose, Red Fox. Using these as a guide, the reader will soon see that the illustrations are accurate. If you want to examine the accuracy further, then you can verify details like the facial features of the Greater Horshoe Bat. However, not all of the species are covered by this fine artwork. I estimate that a little over 67% of the 556 species are depicted [although some of the non-illustrated species are in other, readily available, books].

The book has a great introductory section covering geography, the history of mammalogy in China, and conservation. This includes some useful maps and photographs. The text consists of the typical sections on characteristics, distribution, natural history, additional comments, and status. I was pleased to find this information is current and honest. Chinese literature meant for the West often glosses over key problems. This is not the case here, and the status of the Tiger, for example, is clearly stated. The reasons for its decline are given frankly. As this book covers 81 species more than I have on my existing Chinese mammal list, I tried comparing the two. I gave up after about 150 species because there were considerable differences. Many additional species, primarily from the fringe areas of Xinjiang, Xizang and Yunnan, were included and many others were omitted. I realised many of the missing ones had been assigned a new genus name making direct comparison more difficult. I did wonder why the Eastern Black Crested Gibbon (*Nomascus nasutus*) was not mentioned except in a list of subspecies. This is generally regarded as a full species and is considered the most endangered primate. There are a few [in the low tens] on Huinan [plus a similar number in Vietnam]. Other species like the Manchurian Zokor *[Myospalax epsilanus*] and the Chinese Scrub Vole [*Microtus irene*] are not even mentioned, yet are listed in Duff and Lawson's Mammals of the World and other references.

In addition, there are some changed common names — Onager is called a Kulan, for example. Also only five coastal species of marine whales out of over two dozen pelagic species are included. [However an Appendix lists an additional 29 cetaceans]. Yet all five possible seals recorded, mostly as vagrants, on China's coast are in the book. Another problem is characterized by the distribution of the Northern Birch Mouse, *Sicista betulina*, given by some authorities as being in China, but others as being absent [Including this book]. I think that all of these differences reveal the status of the taxonomy of Chinese mammals and the need to increase research. I will now use this book as the authoritative list, but will likely still consider fringe species.

The issue I have with the text is in the "characteristics" sections. The descriptions will be difficult to use in the field as there is very little comparison with like species. The descriptions are generic enough to overlap and the illustrations are similar. For example, Jerboas are very difficult to separate. I know how hard it is to see these small fast creatures [the Great Jerboa goes over 40 km/hr!] in the field. There is a key to each genus, but this is more useful for museum specimens. [In fact there were a few places where I felt strong museum overtones as opposed to field experience. However, the book is not called a *field* guide.]

In addition to re-assigning genera, the authors have split the Eurasian Moose or Elk from the North American Moose. In China there are two widely separated populations: one in Xinjiang [north west] and one in Heilongjiang [north east]. They have made this split based on the larger size, redder fur and bigger dewlap of the "American" Moose. No other reference makes this difference.

The range maps plot actual museum and other records rather than shaded estimations of current distribution. This is more precise and factual, but may not represent today's status and may be more of a historical record. This will mean the reader will have to interpret the data carefully so as not to get a wrong impression.

I did spot a couple of errors. Savi's Pipistrelle's range is given as Xinjiang ... to Northern Europe. It actually is found in Greece, Italy and eastern Spain, not what I consider northern Europe. The index indicates that the Tibetan Antelope is on Plate 60 when it is depicted on Plate 57. I also question the range map of the Spotted Seal, shown with many specimens going

far inland. I would be surprised if this pack-ice loving beast would go up fresh water rivers.

Notwithstanding my comments, this is a much-needed guide and it will be indispensable for naturalists and mammalogists for years to come.

ROY JOHNS

2193 Emard Crescent, Ottawa, Ontario, K1J 6K5 Canada

Birds of the Saskatoon Area

Edited by Anna L. Leighton, Jim Hay, C. Stuart Houston, J. Frank Roy, and Stan Shadick. 2002. Nature Saskatchewan Special Publication Number 23, Regina and Saskatoon Nature Society, Saskatoon. 345 pages. 40.00 CAD [30.00 CAD to Saskatoon Nature Society members] Paper.

During my second encounter with the late J. Bernard Gollop in Regina some time between 1968 and 1970, the late Margaret Belcher and her sister, Mary Houston, mentioned that his planned book on the birds of the Saskatoon area would probably be the next of the esteemed Saskatchewan Natural History Society special publications to appear. Unfortunately, Bernie did not live to see it in print, but 77 authors and six editors finally brought his 1965-1988 efforts to fruition. The long gestation period produced an outstanding addition to Saskatchewan's ornithological literature.

This largest book in the series to date is also the first to be co-published [by the Saskatoon Nature Society] and is the fifth in the Manley Callin series on birds of specific areas of the province. It is jammed with information, with even the covers and fold-outs from the covers containing information [an area map, a Landsat image of the study area and a few tables]. Introductory material covers the first 68 pages of text, including publication blurbs, tables of contents, drawings, maps and photographs, a dedication to Bernie Gollop, a preface, a foreword by Farley Mowat, a poem, acknowledgments, chapters on birding aids, histories of birding in the area and of the project, a detailed chapter on habitats and other ecological influences on the local avifauna, a detailed chapter on "hot spots" [essentially a bird-finding guide], a list of "unpublished" sources [including published seasonal compilations] consulted, a list of abbreviations, a topography and a glossary. These are well illustrated with figures, maps and drawings. The bulk of the text consists of 340 species accounts in taxonomic order except for one [Prairie Warbler] that was added while the book was in late stages of production. Eight appendices, a list of references cited and indices to English and French bird names close the book.

The species accounts are preceded by a two-page introduction, explaining their contents and definitions used for seasonal occurrence, status in the area, abundance, tables of arrival and departure dates and other general information. Species accounts range in length from two paragraphs to two and a quarter pages, depending on regularity of occurrence in the area, amount of knowledge of the species' life history features in the area, numbers banded in the area, and other factors, such as change in status, locally, provincially, and/or generally. If migratory, earliest and median spring arrival and latest and median fall departure dates are included. If banded, numbers of the species banded in the area are listed, as are numbers (if any) recovered inside and/or outside the Saskatoon bird area. If known to nest, data are included on whatever details of nesting biology, chronology, habitat and/or success are available. Remarks on population changes and their believed causes are also included if appropriate. Drawings accompany several species accounts. Current English, French and scientific names and one or more four-letter species code(s) are indicated for each species. Former English names are also indicated for several. Nineteen nesting species are listed as hosts of Brown-headed Cowbird documented in the Saskatoon area in both the cowbird and the host species accounts. Several miscellaneous observations of biological, historical or population trend interest are also mentioned, often in a "side bar" or box.

The book ends with a series of eight appendices (on annual Christmas, May Day and fall counts, local Breeding Bird Surveys, numbers of each of 79 species banded in the area, numbers of birds banded by each bander who has banded in the area, nest-box dimensions and requirements for 12 species and a list of 12 theses based on birds studied within the area), a list of references cited and indices in English and French to the first page of each species account.

This volume continues the trend of improving on the already high quality of earlier contributions in this series, using as many sources of published and unpublished sources as possible. Although some variability in style is inevitable in a book with so many authors and editors, the quality of writing and accuracy of information are high throughout. I noted a few minor grammatical deviations, but few errors or omissions of substance. The statement (page 284) that Dickcissels "continue to breed" in southern Manitoba implies regular occurrence there. While they occasionally nest there, rarely in fairly large numbers, their occurrence is irregular, often with several years between sightings (Davis et al. 2003). Minor errors include the omission of the hyphen from screech-owl (page 68), reference to Townsend's Solitaires as "thrush-sized" (page 232), implying that they are not thrushes and a few instances of species names in lower case. The vocalization of Baltimore Oriole referred as a "call" (page 291) ap-

pears to be the song. Cross-referencing between species accounts is quite thorough, but the list of 19 known local cowbird host species (page 290) omits Hermit Thrush (page 235) and Common Yellowthroat records (page 259). Also, a record of House Sparrows nesting in Bank Swallow holes is mentioned in the swallow account, but not in that of the sparrow and a case of hybridization between Eastern and Mountain bluebirds is mentioned only in the Eastern species account. Odd omissions from the glossary are the terms "albinism" and "leucism," especially since the less common "melanism" is included. An odd feature, though not an error, is the use of U.S. spelling for behaviour, centered, colour, favoured, harbour, moulting, neighbourhood and variants of these. The difference in slope of the bill between Tundra and Trumpeter swans, a feature much easier to see than the visual differences noted, would have been a useful addition to the identification tips in the swan accounts (pages 89 and 90). The header for Wilson's Snipe indicates that two nesting records have been documented in the area, whereas three are mentioned in the text. The record of a robin feeding a young cowbird (page 237), while interesting, is not definitive evidence of successful parasitism by cowbirds on robins, as non-parental birds sometimes feed offspring of birds of other species (for example, Salt 1997). Most references cited are included in the reference list, but one by Allen (1952) is cited as both Allan [incorrectly] and Allen on page 138, one by Dunn et al. (2000) cited on page 189 is not listed unless 2002 is intended, the title is missing from a paper by Greenberg and Droege, the pages of the 1996 owl paper by C. S. Houston should be 125-133 [not 25-132] and the second author of the book by Robbins et al. should be B. Bruun, not B. Brown.

Although such regional works serve primarily to document occurrence, dynamics and changes in local bird populations, they also serve to document various life history observations that the author(s) may otherwise never find time to write up. Examples of such tid-bits in this book include fondness of Snow Geese for peas, television tower casualties of Green-winged Teal, albino and/or "partial albino" Ruddy Duck, magpies, Mountain Bluebird, Yellow-rumped Warbler and Yellow-headed Blackbird, a pair of Red-necked Grebes incubating golf balls, predation by American Crows on Eared Grebe eggs, cormorants perching on power lines, a dry land nest of an American Bittern, Willet courtship flight, magpies chasing and catching bats and eating berries, a Bank Swallow colony in a hole in a wheat field, House Sparrows nesting in Bank Swallow holes, robins nesting on antlers and large numbers of starlings flycatching.

Another measure of success in such regional works is the degree to which they stimulate publication to fill in gaps and document changes. Judging by the number of notes and papers on bird observations and research in the Saskatoon area that have appeared in ornithological and natural history journals since "Birds of the Saskatoon Area" appeared in print, this volume has succeeded in that respect as well. It is an important contribution towards a forthcoming two-volume account of the birds of Saskatchewan.

Book Review Editor's note: In a brainstorming session between the Editor, Francis Cook and myself, on future directions, we agreed I would investigate suitable websites and, if appropriate, include their reviews. I proposed we use Brian Coad's site as a test case, hence the following review. If others know of similar suitable sites [Cornel University, USDA and USGS come to mind] please e-mail me [r.john@ rogers.com] with your suggestions.

Brian Coad's Ichthyology Site

http://www.briancoad.com/main.asp?page=fishdictionary.htm
By Brian Coad. 2008.

Unlike books, websites are not static. This is the case with Coad's site, which is defined as a work in progress. What it currently contains is sections on Projects, Fishes of Canada: Annotated Checklist, Dictionary of Ichthyology, Freshwater Fishes of Iran, Fishes of Canada's National Capital Region and Freshwater Fishes of Iran.

The first section lists the author's eight current projects, with a few sentences of explanation. The checklist of Canadian Fish is a straightforward list of scientific and common names in both languages, plus occasionally a few comments. The dictionary, co-authored by the late Don E. McAllister, defines terms specifically used in the study of fish and includes some generally used common words.

The Freshwater Fishes of Iran has individual species accounts arranged by genera. These start with an introduction to the genus. Each detailed account has sections on the Common name in English and Farsi with the phonetic pronunciation, Systematics, Key characters, Morphology, Sexual dimorphism, Colour Size, Distribution, Zoogeography, Habitat, Age and growth, Food, Reproduction, Parasites and predators, Economic importance, Conservation, Further work and Sources.

These accounts are illustrated [black-and-white line drawings] and give the reader a very exhaustive understanding of the individual species.

Fishes of Canada's National Capital Region [NCR] has similar coverage to the above. Also included are photographs of out-of-water fish where these are available and range maps within the National Capital Region. I decided to try out the site to identify small fish I saw in Mud Lake in Ottawa. After comparing descriptions and other information I decided it might be a Central Mudminnow. To be certain I would need the fish in hand. I might raise eyebrows, or worse, if I started netting fish in a public park.

The Freshwater Fishes of Iraq contains only a checklist and bibliography at this date.

Some of the advantage that this web site [and all others] have is that material [such as photos] can be included as required, poor quality photos can be replaced if better become available, multiple photo can shows all features (not the case in a book where cost and space are limitations), text and other errors can be corrected, feedback from readers is easily incorporated, new information can be added as science progresses, in some cases differing view points can be presented at length, saving on costs of paper and distribution over the book format. The site can be accessed from anywhere in the world [with Internet access] without needing to carry around hard copy, it is copied by students, researchers and naturalist for their own projects

This site is a wonderful source of information in a subject area that is often difficult to access. It is very easy to navigate and loads quickly [but it is not as user-friendly as a book]. I am not one to load up my favourites folder unless it is a site I will use frequently. I suggest this is one of those sites, especially if you live in the Ottawa-Gatineau area (National Capital Region). I also need to trust the information supplied. The generic question remains in that sites like this have not been reviewed as a book would be. Readers on the internet will need to verify the quality of a website before trusting the data. As Brian Coad is a respected research scientist (at the Canadian Museum of Nature) with extensive field experience in the Ottawa District and Iran, this is not an issue, despite its being a personal, rather than an institutional site. At least you should take a look at it as I am sure you will learn as I did.

BOTANY

Exploitation and Utilization of Chinese Spice Plant Resources

By Zhang Weiming and Xiao Zhengchun et al. 2007. Southeast University Press. 722 pages. Price 186.00 CNY.

Spice plants are in a special category in the plant kingdom, and have been popularly used for various purposes in different countries or regions of the world. The history of the use of spice has even exceeded recorded history of human beings. Early humans might have used spice plants to preserve meat, fish or other food, reduce the annoying odors of various foods, or increase a special flavor when cooking. Gradually, these began to expand the range of use of spice plants.

Spice plants are closely related to the daily lives of human beings. Systematic research and summary of them is necessary, however, as this has not been well done before, at least in China. Now, this situation has been changed by the publication of the book *Exploitation and Utilization of Chinese Spice Plant Resources* by Zhang Weiming and Xiao Zhengchun et al. The authors have been engaged in research work on spice plant resources for a long time. They have conducted several research projects relating to Chinese spice plants in the last few decades, and obtained valuable and abundant data in this field. Meanwhile, they also collected other abundant information on spice plant resources at home and abroad. Based on these data and information, they produced this massive book.

There are a number of climate zones in China. Different environmental conditions allow for the growth of an abundance of plant species, including spice plants. Except for a few tropical species, most of the spice plants grow in China. China was one of the earliest countries to use spices. There are some records on the aromatic and spicy plants in the Book of Songs, the Book of Mountains and Seas, and other book that are more than 2000 years old. Over a long time, due to the various usage of different types of spice plants in cooking, the people living in various areas of China formed a variety of eating habits, reflected in the so-called eight genres of cuisine of Chinese dishes. Hence, we might say that one of the most important reasons that Chinese food (or any other regional food) enjoys a world-wide reputation is its unique use of spices in cooking.

The indigeneous spice plants in China are abundant. Furthermore, over the years, China introduced many foreign-origin species. The book not only is a systematic and comprehensive monograph on the spice plant resources of China, but also has its value as a reference for other related countries. The book is divided into two parts. The first part is a general introduction to spice plants, including the history of spice plants, the general situation of Chinese spice plant resources, the main ingredients and the application of spice plants,

the processing technology and the development of spice plants, and the strategy of the development of China spice plant resources. The second part is the special issues, including a total of 134 kinds of commonly used spices, and more than 200 spice plant species. For each spice plant species, the ecological environment, history of use, chemical ingredients, comprehensive methods of use, exploitation of related products, standardization and cultivation techniques, and so on were comprehensively introduced. The typically introduced spice plant species in this part include *Capsicum frutescens*, *Allium sativum*, *Aglaia adorata*, *Allium cepa*, *Allium fistulosum*, *Allium porrum*, *Allium sativum*, *Artemisia vulgaris*, *Illicium verum*, *Foeniculum vulgare*, *Levisticum officinale*, *Mentha haplocalyx*, *Pimpinella anisum*, *Sesamum indicum*, *Zanthoxylum bungeanum*, *Zanthoxylum simulans*, and *Zingiber officinale*, among others.

The book was well written with few errors, in a style of writing that can be easily understood by non-scientists. As a comprehensive book, it is suitable for anyone who is engaged in the various areas of research and application of spice plants.

Arctic Hell Ship

By W. Barr. 2007. University of Alberta Press, Ring House 2, Edmonton, Alberta T6G 2E1. 318 pages, 34.95 CAD Cloth.

More of a human history than a natural history book, this tale covers part of one of the great sagas of Canada's north. The Franklin Expedition left Britain with high hopes and the best resources available — well almost. It vanished in 1845 and spawned at least two dozen searches to solve the mystery of the disappearance. These efforts in turn have led to a flood of books and scholarly articles.

So do we need another treatise? The answer is yes in this case. Barr's contribution covers the 12th search by Captain R. Collinson aboard the *HMS Enterprise* with Robert John Le Mesurier M'Clure, as second in command, on the *HMS Investigator*. Barr gives us an extremely detailed description of life on one of Her Majesty's ships in the 1800s. So often the other books concentrate on the leaders and their accomplishments, so we learn little of how the crew fares. Barr remedies this by telling us about many of the individual sailors. The "story" is very simple. This was a voyage that produced limited results and suffered a lot of bickering between the officers. As a result, the ship's, logs and letters contain irritating daily details that show what life was really like.

Collinson was a good seaman and surveyor, but he was clearly not a leader. He picked on very minor transgressions and turned them into major disciplinary actions. He sowed unnecessary seeds of discord, interspersed by bouts of humanity. In hindsight, his biggest failure was that he did not do enough. He was charged with rescuing Franklin's men and given the resources to do it, and yet he spent a lot of time sailing back and forth, unable to make a clear decision. His sledging trips were too little and too late. The other ships in his command (which got "separated" early in the expedition) went farther and did more. When Collinson did make progress he found notes from either M'Clure or Dr. John Rae showing that they had searched the area earlier. In the tough conditions on board ship during an Arctic winter this debilitating caution and indecisiveness coupled with petty decisions on discipline must have made an unhappy ship full of exasperated people.

Collinson returned to Britain, having failed to solve the Franklin issue, demanding courts-martial for his officers. The lords of the Admiralty wisely declined to take action. Public exposure of such silly shenanigans would do the service no good.

The most notorious British naval captain of this era is Bligh. In spite of the fact that his reputation owes more to the movies than reality, Bligh was a superb navigator, excellent seaman and a relatively humane captain. He personally intervened in the trials of the captured mutineers, got some set free and obtained reduced sentences for others. He died as a Vice-Admiral. Collinson's dithering and his stubborn need for absolute discipline would have made him a better candidate for Hollywood's spite, yet even this would be unfair. How would we all fare under such harsh conditions?

Collinson did make Vice-Admiral, after serving at Trinity House, the establishment that maintained the aids to navigation, where he rose to deputy master. He remained at Trinity House until retirement, clearly a better bureaucrat than expedition leader. Perhaps the error lies with the lords of the Admiralty. They fell into that awful trap. They promoted a very technically competent person to a supervisor, a move that does not always work. In particular, voyages to the Arctic, even today, need competent leaders. Collinson did not come close to Nansen, Shackleton, Amundsen, or even Scott in his ability to deal with people.

While Barr has produced a minutely detailed document, using all available evidence, rather than a dis-

tillation of the key events, it is those details that give the book its appeal. I found I wanted to read just one more paragraph each time before I put the book down. I was surprised when I realized I was over half way through the book and it seemed I had just started. As I stated initially this is really a history text, but it covers a key era in the story of Canada. The only important note of natural history concerns the surgeon, Edward Adams, for whom the Yellow-billed Loon was named *Gavia adamsii*. It is well worth the read if you love the Arctic, enjoy history or are a Franklin buff

Eighteenth-century Naturalists of Hudson Bay

By Stuart Houston, Tim Ball and Mary Houston. 2003. McGill-Queen's University Press, 3430 McTavish Street, Montreal, Quebec, H3A 1X9. xxiv + 333 pages 49.95 CAD Cloth.

In 1959, C. Stuart Houston and Maurice G. Street began to introduce prairie naturalists to the pioneering contributions of employees and other associates of the Hudson's Bay Company and to expand our understanding of the natural history of Canada's Arctic and prairie regions (Houston and Street 1959) in the first of a long series of articles, books, notes and papers by Houston and numerous colleagues on biographies of specific contributors and the history of various aspects of these contributions. In this volume, Stuart and his chief collaborator (Mary I. Houston) bring many of the details of their earlier publications together, expand on the European collaborators of these naturalists and compare the Hudson's Bay contributions with approximately contemporary efforts in South Carolina. They also collaborate with Timothy E. Ball in outlining the contributions of H.B.C. officials in documenting climatological details at various sites and their changes over a long time period and with Arok Wolvengrey and Jean Okimasis in documenting Cree names for numerous natural history species in the lands of the vast territory formerly controlled by H.B.C.

The book opens with a series of introductory sections, including a list of McGill-Queen's "Native and Northern Series" (of which this is the 34th), a dedication to William B. Ewart (whose efforts led to the moving of the extensive Hudson's Bay Company archives from England to Winnipeg), lists of contents, illustrations and tables, eight colour plates of birds originally published in two of four 1743-1751 volumes by George Edwards, acknowledgments, a list of supplementary documents available through the internet, a list of abbreviations and a foreword by the Keeper of the Hudson's Bay Archives, Judith Hudson Beattie. The main text of the book (pages 1-142) consists of an unnumbered introductory chapter, followed by 12 numbered chapters. Seven appendices occupy almost as many pages (pages 143-251). About 40 pages of footnotes, 25 pages of references and a 14-page index close the book.

The main text starts with a short outline of the history of Hudson's Bay Company activities in North America and the role of HBC officials in documening natural history features of much of the prairie provinces, Ontario, Quebec, Nunavut and adjacent areas in collaboration with native North Americans and European scientists. The first numbered chapter consists of brief biographies of seven European scientists who received and/or examined animal specimens collected by HBC personnel, described and often named them, and wrote the first accounts of their behaviour and other natural history features. The role of these specimens in developing Linnaeus's system of classification of plants and animals is outlined. Eight chapters follow on the contributions and efforts by eight specific HBC officials (Peter Fidler, Andrew Graham, Samuel Hearne, Thomas Hutchins, James Isham, Alexander Light, Humphrey Marten and Moses Norton). The tenth numbered chapter summarizes these contributions, lists Hudson Bay area bird species mentioned in ten early manuscripts, provides several background details and notes several corrections and omissions in earlier publications. The eleventh chapter, based primarily on four years of archival research by Ball, outlines weather, climate and climatic changes in the area, as documented through records of 30 or more years at 30 HBC posts. The final chapter outlines early contributions to North American natural history by early settlers of Charles Town, South Carolina, when that area was still a British colony. Brief biographies of two contributors of meteorological data and two natural history collectors are included, as well as a list of species named as new in Mark Catesby's 1729-1747 two-volume treatise on the birds of South Carolina (58 from "South Carolina," seven from other parts of eastern U.S. states, seven from the Caribbean, and one from "Quebec."

Seven appendices cover about 100 pages. The longest (about 50 pages) by the Houstons, Jean Okimasis and Arok Wolvengrey lists words used in the eighteenth century in four Cree dialects for various taxa that live in the territory controlled by the Hudson's Bay Company. Another lists departure and arrival dates and the captains of ships sailing between York Factory and Europe from 1716 to 1892.

Smiles will cross the faces of Saskatchewan naturalists, long aware that two of their most prominent members (Margaret Belcher and Mary Houston) were sisters, when they read that one of two ships captained by a Belcher (twice) was "Mary." A two-page appendix by Deirdre Simmons outlines the history of the Hudson's Bay Company Archives. Others concern ten man-

uscripts that have variously been attributed to Andrew Graham and Thomas Hutchins, and plagiarism of Graham by Hutchins. The Houstons provide an interesting account of their research in the archives, in London and at a symposium in the Orkney Islands that brought them to the conclusion that these manuscripts resulted from collaboration. Other appendices concern the ten-year cycles of various northern birds and mammals, the effects of nineteenth century trade on Trumpeter Swans, and the naming of Canada Goose prior to the official existence of Canada. I assumed that the latter was a combined reprint of two earlier publications in *Blue Jay* (Houston 1994, 1995), but some of it presents additional findings of historical research that was stimulated by the earlier notes.

Naturalists interested in historical aspects of nature study will find plenty of interest in this volume. It is written well and researched thoroughly. I found no substantial errors, although a few references cited were either not included in the literature lists or the publication dates and/or author list in the text differed slightly from those in the literature list. One reference (Ross 1834) is listed in a footnote (page 256), but not in the references. Three references cited are not included in the literature list (Gmelin [1788 on page 140], McIntyre and Houston [1999] on page 269) and Rousseau [1969] on page 279, although enough information on the latter is included to enable a reader to track it down). The 1983 book by Peck and James should be listed as Volume 1. Footnote 39 on page 255 on William Wales should refer to Chapter 11, not 12. References to Appendix E and Figure 3.13 on page 52 apply to Appendix F and Figure 3.14; respectively. The abbreviated forms of the authors' names from the more usual versions that they use in publications (Timothy E. Ball, C. Stuart Houston and Mary I. Houston) provides potential confusion for bibliographers who may think that other, presumably related, authors are involved, especially as their usual publication versions are used in some appendices. As noted by Meyer (2004), some of the appendices would be more appropriate within the main text. Although the literature list is substantial, readers new to the subject who wished to follow up with further reading would have benefited from inclusion of more of Houston's previous biographies, book chapters, notes and papers on some of the subjects covered. Similarly, although biographical references are included for many people, none are included for a few (for example, William Rowan) for whom several are available. None of these criticisms detract substantially from the overall high quality of this excellent contribution to the history of nature study in North America.

Hunters at the Margin: Native People and Wildlife Conservation in the Northwest Territories

By John Sandlos. UBC Press, 2029 West Mall, Vancouver, British Columbia V6T 1Z2. 360 pages, 85.00 CAD Cloth, 39.95 CAD Paper

Professor Sandlos has written a very well-researched text on three major conservation issues. He examines the plight of the Bison, Muskox and Caribou in Canada's north. The author has examined the questions raised about hunting of these three key species and the development and enforcement of laws relating to them. He has done this with a very sympathetic attitude towards Canada's original inhabitants. He compares the lifestyle and requirements of aboriginals to the efforts of Ottawa's bureaucrats to control hunting and to conserve these mammals. These two philosophies are rarely compatible, and this leads to conflict.

I had a hard time reading this book. While I understand the author's sympathy with Canada's aboriginal people I found his constant innuendo very galling. When discussing the native viewpoint he writes without emphasis. When writing about the non-native people's actions he frequently uses parentheses, causing the reader to doubt the adjective's veracity. When defending the native people Sandlos ignores much pertinent information. He proposes the natives are not the wanton killers portrayed by white policemen, wardens and travelers, but long before the arrival of the white man the natives hunted Mammoths, Giant Sloths and others to extinction. This was also before climate change pushed these creatures over the edge [as in Europe]. The latest book on Caribou (Bergerud et al. 2007) notes that after an influenza epidemic decimated native populations, Caribou increased [see review this issue]. In my own experience, two years ago at Cambridge Bay, I was informed the hunting ban on Muskox had been lifted a few months earlier and the town's residents had shot the entire local herd. I had to travel out of town for an hour by truck and an hour and a half on foot to see distant Muskox on this island.

Before the arrival of whites, there were few natives in the north; it was too hostile a climate. Living was easier on the plains with its abundant Bison. In fact the author provides evidence for this concept when he quotes a convicted poacher, Joseph Wakwan, as preferring to hunt the larger Bison over the legal Moose.

The natives moved north after they found they could make money for guns and supplies by trapping Beaver. The demand for Beaver hats was purely European.

I do not know if the author has been involved in creating laws, but I suspect not. This a long and complex process where nobody wins everything they want. At the conclusion you achieve compromise regulations that all can accept, more or less. To constantly criticize the Ottawa law-making bureaucrats, who were trying their best with the information and attitudes of the day, is a futile process. Trying to judge past events with today's understanding is fun, but useless. National committees have learned long ago not to react too quickly to the latest reports and studies. It takes time and careful study to be certain any new data are valid. There have been many reports that claimed something was bad, only to be followed by another that said it was good. We do not want our laws flip-flopping with every new announcement.

If we applied Sandlos's logic that white man's laws do not match aboriginal situations and therefore really do not apply, then I could ignore the laws of England as I am Welsh, a true English aboriginal. [The Welsh inhabited all of Britain before they were conquered by the Angles and Saxons. These in turn were reduced to serfdom by the Norman French.] I, like all those in England, have to obey today's laws. Such is history. The Canadian native people actually fared reasonably well for a conquered community. Compare their fate to that of the Inca after the arrival of the Spanish or the original inhabitants of the Amazon after the Portuguese took over. The arrival of the white man brought white-man's laws, as well as welfare, modern medicine and current technologies. Whether these are good or bad is a moot question. When I wrote my last report on people of the north, the data sets I accessed on diet used by northern residents showed that a high proportion of junk food had replaced food gathered from the wild. In my view, this represents a poor choice; on the other hand, I do not recall any native village starving or freezing to death [as happened in the past, before the arrival of the white man]. We need to remember we all live in today's conditions, which includes a plethora of laws which we must all obey [Whether we agree with them or not. Ask me about CITES. A well-meaning idea, whose concept I support. In practice it is often counterproductive to conservation and frequently punishes those who are promoting conservation.]

Do not let my criticisms put you off reading this book. There is a lot of useful and thought provoking material embedded in the text. The questions and issues surrounding the native people and wildlife in the north are not easy to deal with and I doubt there will ever be "an" answer. This book makes a significant contribution to the continuing research and debate required to make rational decisions. I just wish it was written in a more balanced and critical style.

The Ornithologist's Dictionary

By Johannes Erritzoe, Kaj Kampp, Kevin Winker and Clifford B. Frith. 2007. Lynx Edicions, Montseny, 8, 08193 Bellaterra, Barcelona, Spain. 290 pages, 19 EUR Paper.

This is a great little book that will be handy for all who study birds. I can easily slip out of my depth when reading a book or article because I do not understand some terms. Typically I stick a mark in the page and later go to my computer for help. Google searches are normally wonderful ways to fill in your knowledge gaps. But this also disrupts the continuity of your reading and lowers the value you can pull from the text. Having a resource that can sit by your side is a big advantage.

So how accurate and comprehensive is the text? First, let me say the authors use the English spellings [colour etc.] This does not mean a European bias as there are plenty of references to purely North American terms [National Audubon, AOU etc.] and the U.S. spellings are included [spishing vs pishing!]. I looked up several definitions of words which are frequently misused and could only find one significant error. Parameter is not "any variable" but a *constant* in an equation that varies in other equations of the same general form [the classic example is the force of gravity — always constant in Ottawa but different yet constant in Banff.] This is an incredibly common error, even among scientists who should know better. I have a few other less significant comments, such as the needless use of *inter*relationship [relationship is fine, particularly in a dictionary] and I would not say the use of "mirrors" for the white tip of a gull's wing is *uncommon* as it is used in most of my books. I thought, too, that the authors could have included newer terms like sahel [note the lower case s] — A region having characteristics of a savanna or a steppe and bordering on a desert — as well as the classic definition of Sahel — a transition zone between the Sahara and the tropical forests to the south.

Each letter of the alphabet starts with a neat black-and-white drawing of a bird. These are not identified, but I could easily determine the species in all but X and Y. Also I could not find the identity of the artist.

Several pages in my original copy were greyed. As this is totally unlike the publisher, Lynx Edicions, who

normally produce beautiful, crystal clear copies, I contacted them. It appears this was an isolated incident; however, you should check the particular copy you intend to buy. Lynx sent me another, perfect copy.

This will be of greatest use to non-professional avid birders who lack formal training. You can quickly resolve the occurrence of melanin, the nature of remiges, the difference between granivorous and graminivorous, mimesis and mimicry and other sources of confusion. This book would have rapidly ended my last bird-term argument — the meaning of leucism — if I had had it handy. It may not be as valuable to professionals, but I think they will likely find it useful too. Buy this one for yourself!

Pioneering Women in Plant Pathology

Edited by Jean Beagle Ristaino. 2008. The American Phytopathological Society, 3340 Pilot Knob Road, St. Paul, Minnesota, U.S.A. 339 pages. 89.00 USD Cloth.

As seen by one woman, an M.Sc. graduate in plant pathology from the mid-1970s, it would appear that women scientists in this field are rapidly proving their abilities to shine with accomplishment in what was once an all male profession; moving from being seen as pretty women hobbyists picking wild flowers to serious taxonomists of vascular and non-vascular plants, many of which are plant pathogens. Agriculture has itself moved from its primitive beginnings of slash and burn to a precise science of food production in the 21st century.

As the possibility that a woman may progress from a mere technician and housekeeper of the laboratory to the more stellar role of research scientist has improved, their research results have proved their abilities. The first woman plant pathologist, hired by the United States Department of Agriculture, was Effie A. Southworth, in 1887. Her most significant contribution was the description of the pathogen *Colletotrichum gossypii*, the cause of anthrocnose on cotton, and the recommendation of measures of control of this disease. In 1895, Flora W. Patterson became the first woman mycologist at United States Department of Agriculture. She is remembered for the development of the U.S. National Fungus Collections, which are still of importance to mycologists and plant pathologists today. She also was very involved with the inspection of imported materials for invasive fungal pathogens, and intercepted the dangerous potato wart disease before it was imported into the United States for the first time. Another woman of importance was Edna Marie Buhrer, who brought forward the importance of nematodes in plant diseases; up till 1920 the role of nematodes in crop production was considered unimportant. This led to various treatments of soils with nematicides which results in improved crop production.

In England also the importance of women in this field was recognized at Rothamsted Research Center and among those employed there and making a valuable contribution was Mary Gwynne. She started her career in 1917, worked mainly on diseases of cereal crops, and in 1960 was awarded the Order of the British Empire for her contribution. Margaret Newton, at MacDonald College, McGill University, was a Canadian woman who made a considerable contribution to the knowledge of stem rusts of wheat, so important to the agricultural economy of Canada. At this period of time in the early twentieth century, women from European countries were also making their contributions.

It is recommended that this book be on the shelves of every plant pathology department library, not only to show the valuable contributions made by these scientists, but also to show the courage and dedication of these pioneering women in the face of the prejudices of those times. This book also highlights the importance of this field of science to the agriculture of the American continent and the safety of the world's food trade. We have here a book about pioneering women plant pathologists who have overcome prejudice to make considerable contributions to the economy of North America.

Pioneering Women Plant Pathologists is edited by Jean Beagle Ristaino; and the careers of 26 women scientists are outlined by 37 authors from the United Kingdom, United States of America, Canada, Portugal, Italy and the Netherlands. It is most interesting to read, and gives one a very good indication of what these plant pathologists have contributed to this field.

ELIZABETH PARNIS

Birdwatcher: The Life of Roger Tory Peterson

By Elizabeth J. Rosenthal. 2008. The Lyons Press, Guilford, Connecticut. 437 pages. 34.95 CAD.

Roger Tory Peterson's parents could not afford to send him to college and he had no formal training in science. He moved to New York City, where he painted designs on furniture in the mornings to earn enough to attend art classes in the afternoon. He joined the Bronx County Bird Club, following the new concept of identifying birds in the field without the need to shoot any specimens for confirmation. The club's pres-

ident, Ludlow Griscom, was an early advocate of this method and RTP soon rivaled him in auditory and visual skills.

RTP's first book, *A Field Guide to the Birds*, published 27 April 1934 at the height of the depression, made bird identification easy for the first time. His wide-ranging combination of skills and knowledge made possible the succeeding Peterson field guides, all published by Houghton Mifflin in Boston. Each used the "Peterson system of field identification," with an arrow pointing to important field marks for each species. Millions of copies were sold. His first bird field guide went through four more revisions, the last posthumously; it was 85% complete when he died a month before his 88th birthday. Through his multifaceted achievements: books, articles, photographs, movies and paintings, Peterson became the best-known and arguably the best-loved naturalist in the world.

RTP's first teaching experiences were at a boy's camp in Maine, and in writing pamphlets for members of Junior Audubon Societies. He remained a teacher all his life. His dedicated second wife, Barbara, managed his home and business affairs with great distinction, freeing him for extensive world travel.

Liz Rosenthal's informative book is based largely on 147 interviews with 117 people, including many of the "who's who" of the birding world. Their words and memories provide inside stories about their interactions with Roger. The inevitable result of this methodology is a few minor omissions. As one example, Rosenthal's book omits one of RTP's early pupils at the Rivers School near Boston: Eliot Richardson, who much later became U.S. Attorney-General and successfully nominated RTP as the teacher who had influenced him most, resulting in the nationwide "Teacher of the Year" Award. Nor we do we learn that RTP's final total of honorary doctorate degrees reached 23.

Conservation themes are interwoven throughout this book. These began with Peterson's long involvement with the National Audubon Society, as a director, secretary, columnist in their magazine, and presenter of some of their most popular screen tours. He helped found the World Wildlife Fund, helped save fragile areas such as the fabulous Coto Doñana in Spain, Midway Atoll in the Pacific and Aldabra Atoll in the Indian Ocean, and helped Kenya's Lake Nakuru become a national park, where a million flamingos form "the world's greatest ornithological spectacle." He photographed all 17 of the world's species of penguin.

We learn of Peterson's close friendships with two other world-famous ornithologists, James Fisher and Sir Peter Scott. As evidence of his stature among professional ornithologists, Peterson served as president of the Wilson Ornithological Society and as Vice-President of the American Ornithologists' Union (AOU). An icon, he received the William Brewster Award from the AOU in 1944 at the early age of 36; Presidential Medal of Honor, presented by Jimmy Carter; Audubon Medal from the National Audubon Society; Gold Medal of the World Wildlife Fund, presented by Prince Bernhard of the Netherlands; Order of the Golden Ark from the Netherlands; Linnaeus Gold Medal from the Swedish Academy of Sciences, and the Smithson Medal from the Smithsonian Institution. He attended the dedication of the Charles Darwin Research Station in the Galapagos. RTP was happiest when serving as naturalist-lecturer aboard Lars-Eric Lindblad's *Explorer* on cruises to the Antarctic, Galapagos, Amazon River and Aldabra Atoll.

I detected two errors. Iceland is NOT north of the Arctic Circle (page 133). The Peregrine nest on the Sun Life building was in Montreal, not Toronto (page 229). I also regret that, in a book about people, the people index is incomplete, omitting some names entirely, and incompletely listing mentions of others.

Elizabeth J. Rosenthal, a graduate in both journalism and law, has previously written *His Song: the Musical Journey of Elton John*. Her Peterson life deals with a man of very different but not lesser talents, who was unusually helpful to beginner and expert alike, and whose personality shines through in the interview process. The potential audience includes the millions of people who began nature study with a Peterson field guide.

News and Comment

Bill Cody Receives Honorary Doctorate of Science from McMaster University, June 5, 2007

William James (Bill) Cody was born in Hamilton, Ontario in 1922. He grew up in Hamilton during the Depression. During summers, he worked on his uncle Bruce's fruit farm near St. David's in the Niagara Peninsula. He always enjoyed the outdoors, but it was with the help of McMaster University's Professor Lulu Gaiser that his love for plants grew. Bill received his bachelor's degree from McMaster University in 1946.

That same year, Bill joined the Canada Department of Agriculture at the Central Experimental Farm, in Ottawa, as Junior Agricultural Assistant. He was subsequently promoted to Senior Agricultural Assistant, Technical Officer and then Research Assistant. His enthusiasm for the outdoors led him to travel extensively during the summer months across nine provinces and two territories. During these excursions, he collected over 35,000 plant specimens. He has published over 343 articles, including books, scientific papers, and popular articles. He is Canada's leading expert on the flora of the Yukon and is an Honorary Research Associate with Agriculture and Agri-Food Canada.

Bill was appointed Curator of the Vascular Plant Herbarium in 1959. He held this position for 28 years. Under his supervision it became the largest vascular plant herbarium in Canada with more than one million specimens, including the thousands collected by him personally. The herbarium provides a basis for research and identification of economically important plants in Canada.

Officially retiring in 1987, after 41 years of service, Bill continues to go to the office. His expertise in identifying specimens and his knowledge is sought after by the younger generation of botanists. He remains an internationally recognized authority in Canada and continues to contribute to the development of the collection.

He joined the Ottawa Field-Naturalist's Club when he arrived in Ottawa in 1946. The position of Business Manager of a scientific journal, *The Canadian Field-Naturalist* was his for over 50 years. His duties included managing finances, monitoring stock, billing for reprints and public relations.

Bill was married for 47 years to Lois and together they raised five children: David, Margaret, Leslie, Douglas and Gordon. Having sung in a barber shop quartet and church choir, his joy of music was very evident. Bill's baritone voice could be heard resonating throughout the halls of his office and apartment building. He often had a pun or quip on the tip of his tongue.

In recent years, Bill had the opportunity to return to the Yukon four times. Each time, he took one of his children to help him collect and log specimens in order to determine range extensions and also to let them experience a place that had been a large part of his life.

Bill is very proud of his family heritage. His father, William MacPherson Cody, was the first appointed anesthetist to the Hamilton General Hospital. Also, his second cousin, 3 times removed, was William Frederick Cody, known to most as "Buffalo Bill" Cody, a famous hero of the American Wild West.

Among the tributes awarded to Bill are the following: the Lawson Medal, most prestigious award of the Canadian Botanical Association (1997); the Distinguished Technical Communication Award of the Society for Technical Communications (1997); induction into the McMaster University Alumni Gallery (2002); The Queen's Golden Jubilee Medal (2002); and the Yukon Biodiversity Awareness Award (2006).

Marine Turtle Newsletter (116)

April 2007. 36 pages: EDITORIALS: Proceeding to the future (M. S. Coyne) — The oldest place where there is always something new (J. G. Frazier) — ARTICLES: An update on marine turtles in Cote d'Ivoire, West Africa (J. G. Penate, M. Karamoko, S. Bamba, and G. Djadji) — An update on sea turtle conservation activities in the Republic of Congo (G. Bal, N. Brehert, and H. Vanleeuwe) — Conflicts and social dilemmas associated with the incidental capture of marine turtles by artisanal fishers in Benin (J. S. Dossa, B. A. Somsom and G. A. Mensah) — Marine turtle mortality in southern Gabon and northern Congo (R. Parnell, B. Verhage, S. L. Deem, H. Van Leeuwe, T. Nishihara, C. Moukoula, and A. Gibudi) — Artificial lights as a significant cause of morbidity of Leatherbacks in Pongara National Park, Gabon (S. L. Deem. F. Boussamba, A. Z. Nguema, G-P Sounguet, S. Bourgeois, J. Cianciolo, and A. Formia) — Observations of marine turtles in relation to seismic air-gun sond off Angola (C. R. Atlas of amphibians and reptiles of Quebec, 2007 inventory

Instructions for participants in the 20th herpetological survey for the Québec Atlas of amphibians and reptiles, coordinated by the St. Lawrence Natural History Society in collaboration with the Ministère des Ressources naturelles de la Faune du Québec. The data from this annual inventory program are incorporated into the Centre de donnees sur le patrimone natural du Québec database; to date this database contains more than 60 000 date entries on Québec species. This provincial inventory is done every year with the important cooperation of volunteers. Contributors are encouraged to send their e-mail address and request for instruction on trasmitting data, Observation cards in paper format are available on request.

Mathieu Oulette, Research Officer, Research and Conservation, Ecomuseum – St. Lawrence Valley Natural History Society, 21 125 chemin Saint-Marie, Saint-Anne-de-Bellevue, Quebec H9X 3Y7; phone 514-457-9449; fax 514-457-0769; e-mail: info@herpetofaune.org.

Russell) Neck musculoskeletal function in the Tyrannosauridae (Theropoda, Coelurosauria): Implications for feeding dynamics — THESES IN HERPETOLOGY AT THE UNIVERSITY OF VICTORIA (Patrick Gregory) a list by student and title for 33 theses (1974-2005): 9 BSc, 18 MSc, 6 PhD — RECENT PUBLICATIONS IN CANADIAN HERPETOLOGY: 17: 2006 (15), 2007(1), in press (1) — ANNOUNCEMENTS New Fiction Book about Sea Turtles: Sand Turtles.

Editor's Report for Volume 120 (2006)

Mailing dates for issues in volume 120(1) 15 July 2007, (2) 1 November 2007; (3) 30 November 2007; (4) 31 December 2007.

A summary of circulation to members and subscribers (institutional and individual) totals for 2006 is given in Table 1. The number of articles and notes in volume 121 is summarized in Table 2 by topic; totals for Book Reviews and New Titles are given in Table 3, and the distribution of content by page totals per issue in Table 4.

Council continued to authorize 40% of membership dues for publication of the journal and all of subscriptions (both individual and institutional). Council also has allocated 80% of the annual interest from the Manning Fund and other capital funds to *The Canadian Field-Naturalist*. Use of the Manning fund portion was broadened on an issue-by-issue basis to offset the publication costs where authors lacked grant or institutional funds to support publication.

The journal was printed at Gilmore Printers, Ottawa, and thanks are due business representative Tom Smith; customer representative Chuck Graham for overseeing production, and Wendy Cotie for typesetting and corrections. Leslie Cody prepared the Index for volume 120; Elizabeth Morton proofed the galleys. When Bill Cody, Businesss Manager for 60 years, was unable to carry on, most of his duties were shouldered by Treasurer Frank Pope and Assistant Treasurer Jim Ward with invoice preparation assumed by the editor. Roy John arranged and edited book reviews and prepared the New Titles listings. Special thanks are due to Jenifer Penny, Program Botanist, B.C. Conservation Data Centre, Victoria, British Columbia, for editing and revising for 120(1) the eight papers on conservation evaluation of some British Columbia plants originated by the late George Douglas and also for preparing the tribute and updated bibliography for Douglas. The journal contents and abstracts are now posted on the Ottawa Field-Naturalists' Club website by webmaster Sandra Garland, and PDFs may be ordered by authors as well as traditional print reprints.

TABLE 2. Number of articles and notes published in *The Canadian Field-Naturalist* Volume 120 (2006) by major field of study.

Subject	Articles	Notes	Total
Mammals	22	6	28
Birds	8	5	13
Amphibians + reptiles	1	1	2
Fish	5	3	8
Insects	3	0	3
Other invertebrates	1	1	2
Plants	13	0	13
Paleontology	1	0	1
Tributes	2	0	2
Totals	56	16	72

Manuscripts (excluding book reviews, notices, and reports) submitted to *The Canadian Field-Naturalist* totalled 67 in 2006, down by 8 from the total for 2005. The following reviewed for papers submitted in 2006 (with number of manuscripts reviewed in parentheses if more than one):

Associate Editors: R. Anderson, Canadian Museum of Nature, Ottawa, Ontario; C. D. Bird, Erskine, Alberta (8); R. R. Campbell, St. Albert, Ontario (2); P. M. Catling, Agriculture and Agri-food Canada, Ottawa, Ontario (5); B. W. Coad, Canadian Museum of Nature, Ottawa, Ontario (6); A. J. Erskine, Sackville, New Brunswick (10); D. F. McAlpine, New Brunswick Museum, Saint John, New Brunswick (4); D. W. Nagorsen, Mammalia Biological Consulting, Victoria, British Columbia (8); W. O. Pruitt, Jr., University of Manitoba, Winnipeg, Manitoba (6).

TABLE 1. The 2006 circulation of *The Canadian Field-Naturalist* (2005 in parentheses). Prepared by Robin Murphy, bmr group, Ottawa. Totals are copies mailed. As some members opt not to receive the journal, membership total here is only those receiving the journal. For total club membership see the Annual Report of the membership committee to the 2007 Annual Business Meeting.

Schueler, Bishops Mills Natural History Center, Oxford Mills, Ontario; J. W. Sheard, University of Saskatchewan, Saskatoon; Brian Slough, Whitehorse, Yukon Territory; K. W. Stewart, University of Manitoba, Winnipeg, Manitoba (3); P. Weatherhead, Queen's Biological Station, Elgin, Ontario; M. J. Wetzell, Illinois, Natural History Survey, Champaign, Illinois; N. Yan, York University, North York, Ontario.

I am also indebted once again to the President of the Ottawa Field-Naturalists' Club, Gary McNulty, and the Club Council for continuing support of the journal; Chairman Ron Bedford and the Publications Committee of the OFNC for editorial encouragement and support, the Finance Committee for input and encouragement to speed things up, the Canadian Museum of Nature for access to its library and the facilities at the Natural Heritage Building, 1740 Pink Road, Aylmer, Quebec, and to Joyce for everything else.

I must add my special thanks due William J. (Bill) Cody who served the club as council member for more than 60 years, vitually all ot this time as Business Manager of *The Canadian Field-Naturalist*. Those of us exposed to Bill's unfailing good humour, determination, efficient focus on the job on hand, and sometimes his inevitable serenades, have lasting memories of the time shared. Bill served with, and kept each on track, five editors (one twice) — Harold Senn to 1955), Bob Hamilton (1956-1961), myself (1962-1966), Ted Mosquin (1967-1972), Lorraine Smith (1972-1981, and me again (1981 — present). Efficient management and financial stability through good times and bad were due in large measure to Bill's initiative which assured, in some periods, the journals very survival.

A decade ago, to mark 50 years of service, the club paid tribute to Bill's contribution to that point with a reception at the Central Experimental Farm, Department of Agriculture, Ottawa, where Bill had spent his whole career, including "retirement", as a research botanist. Stephen Darbyshire for Awards Committee stated in part (1998. Canadian Field-Naturalist 112(4): 719-720):

> "Such long-term service and dedication is unprecedented in the history of the Club and is not likely to ever be repeated. The titles of office do not reveal the extent to which Bill has laboured for the Club. One cannot completely list the jobs that he has taken on (even Bill cannot remember them all), many of which are among the most distasteful and time consuming (imagine the years of dealing with government forms for postage rates, charitable status, etc.). Executive officers have come and gone, Canadian Field-Naturalist editors have come and gone, Council is re-elected every year, but Bill Cody continues as a major constituent of the glue that keeps the Club together and keeps it, and its scientific publication, running smoothly."

Bill continued to perform these duties for close to another decade before failing health forced him pass them on to others. The full truth in the earlier words of tribute has become increasingly realized by those of us Bill left to share his multitude of tasks. Most of the burden has fallen on Frank Pope, already contributing tremendous service as Treasurer of the Ottawa Field-Naturalist's Club, and Jim Ward as Treasurer's Assistant. They have made the transition work.

Advice for Contributors to *The Canadian Field-Naturalist*

Content

The Canadian Field-Naturalist is a medium for the publication of scientific papers by amateur and professional naturalists or field biologists reporting observations and results of investigations in any field of natural history provided that they are original, significant, and relevant to Canada. All readers and other potential contributors are invited to submit for consideration their manuscripts meeting these criteria. The journal also publishes natural history news and comment items if judged by the Editor to be of interest to readers and subscribers, and book reviews. Please correspond with the Book Review Editor concerning suitability of manuscripts for this section. For further information consult: A Publication Policy for the Ottawa Field-Naturalists' Club, 1983. *The Canadian Field-Naturalist* 97(2): 231-234. Potential contributors who are neither members of *The Ottawa Field-Naturalists' Club* nor subscribers to *The Canadian Field-Naturalist* are encouraged to support the journal by becoming either members or subscribers.

Manuscripts

Please submit by post **to the Editor,** in either English or French, **three** complete manuscripts **written in the journal style.** Manuscripts may also be submitted (one copy) by e-mail. The research reported should be original. It is recommended that authors ask qualified persons to appraise the paper before it is submitted. All authors should have read and approved it. Institutional or contract approval for the publication of the data must have been obtained by the authors. Also authors are expected to have complied with all pertinent legislation regarding the study, disturbance, or collection of animals, plants or minerals. The place where voucher specimens have been deposited, and their catalogue numbers, should be given. Latitude and longitude should be included for all individual localities where collections or observations have been made.

Manuscripts should be printed on standard-size paper, **doublespaced throughout,** generous margins to allow for copy marking, and **each page numbered.** For Articles and Notes provide a bibliographic (citation) strip, an abstract, and a list of key words. Generally, words should not be abbreviated but use SI symbols for units of measure. The names of authors of scientific names may be omitted except in taxonomic manuscripts or other papers involving nomenclatural problems. "Standard" common names (with initial letters capitalized) should be used at least once for all species of higher animals and plants; all should also be identified by scientific name.

The names of journals in the Literature Cited should be written out in full. Unpublished reports and web documents should not be cited here but placed in a separate Documents Cited section. List the captions for figures numbered in arabic numerals and typed together on a separate page. Present the tables each titled, numbered consecutively in arabic numerals, and placed on a separate page. Mark in the margin of the text the places for the figures and tables.

Check recent issues (particularly Literature Cited) for journal format. Either "Canadian" or "American" spellings are acceptable in English but should be consistent within one manuscript. **The Oxford English Dictionary, Webster's New International Dictionary** and le **Grand Larousse Encyclopédique** are the authorities for spelling.

Illustrations

Photographs should have a glossy finish and show sharp contrasts. Electronic versions should be high resolution. Prepare line drawings with India ink on good quality paper and letter (don't type) descriptive matter. Photographic reproduction of line drawings should be **no larger than a standard page.** Write author's name, title of paper, and figure number on the lower left corner or on the back of each illustration.

Reviewing Policy

Manuscripts submitted to *The Canadian Field-Naturalist* are normally sent for evaluation to an Associate Editor (who reviews it or asks another qualified person to do so), and at least one other reviewer, who is a specialist in the field, chosen by the Editor. Authors are encouraged to suggest names of suitable referees. Reviewers are asked to give a general appraisal of the manuscript followed by specific comments and constructive recommendations. Almost all manuscripts accepted for publication have undergone revision—sometimes extensive revision and reappraisal. **The Editor makes the final decision** on whether a manuscript is acceptable for publication, and in so doing aims to maintain the scientific quality, content, overall high standards and consistency of style, of the joumal.

Special Charges — Please take note

Authors **must share in the cost of publication** by paying $90 for each page, plus $30 for each illustration (any size up to a full page), and up to $90 per page for tables (depending on size). Authors may also be charged for their changes in proofs. Reproduction of color photos is extremely expensive; price quotations may be obtained from the Editor.

Limited joumal funds are available to help offset publication charges to authors without grants or institutional support. Requests for financial assistance should be made to the Editor when the manuscript is submitted.

Reprints

An order form for the purchase of reprints or pdf will accompany the galley proofs sent to the authors. Invoices for publication costs will be sent when the submission is published.

Igl, Lawrence D., and Douglas H. Johnson. 2007. Brown-headed Cowbird, *Molothrus ater*, parasitism and abundance in the northern Great Plains. Canadian Field-Naturalist 121(3): 239–255.

The Brown-headed Cowbird (*Molothrus ater*) reaches its highest abundance in the northern Great Plains, but much of our understanding of cowbird ecology and host-parasite interactions comes from areas outside of this region. We examine cowbird brood parasitism and densities during two studies of breeding birds in the northern Great Plains during 1990–2006. We found 2649 active nests of 75 species, including 746 nonpasserine nests and 1902 passerine nests. Overall, <1% of nonpasserine nests and 25% of passerine nests were parasitized by Brown-headed Cowbirds. Although the overall frequency of cowbird parasitism in passerine nests in these two studies is considered moderate, the frequency of multiple parasitism among parasitized nests was heavy (nearly 50%). The mean number of cowbird eggs per parasitized passerine nest was 1.9 ± 1.2 (SD; range = 1–8 cowbird eggs). The parasitism rates were 9.5% for passerines that typically nest in habitats characterized by woody vegetation, 16.4% for grassland-nesting passerines, 4.7% for passerines known to consistently eject cowbird eggs, and 28.2% for passerines that usually accept cowbird eggs. The Red-winged Blackbird (*Agelaius phoeniceus*) was the most commonly parasitized species (43.1% parasitism, 49.6% multiple parasitism, 71.2% of all cases of parasitism). Passerine nests found within areas of higher female cowbird abundance experienced higher frequencies of cowbird parasitism than those found in areas of lower female cowbird abundance. Densities of female cowbirds were positively related to densities and richness of other birds in the breeding bird community.

Key Words: Brown-headed Cowbird, *Molothrus ater*, brood parasitism, grasslands, multiple parasitism, spatial variation, temporal variation, northern Great Plains.

The Brown-headed Cowbird (*Molothrus ater*; hereafter cowbird) is an obligate brood parasite that lays its eggs in nests of a variety of host species. Cowbird distribution, abundance, and brood parasitism have long been major topics in avian ecology in North America (Nice 1937; McGeen 1972; May and Robinson 1985; Ortega 1998; Herkert et al. 2003). Cowbird abundance and rates of brood parasitism vary geographically (Robinson et al. 1995; Ortega 1998; Rothstein and Robinson 1998). The cowbird reaches its highest abundance in the northern Great Plains (Sauer et al. 2005*), yet much of our understanding of cowbird parasitism and the dynamics of host and parasite populations comes from areas outside of this region. Nonetheless, some studies have reported high rates of cowbird parasitism and multiple parasitism in the northern Great Plains (e.g., Linz and Bolin 1982; Romig and Crawford 1995; Davis and Sealy 2000; Koford et al. 2000). Robinson and Smith (2000), however, suggested that some of these oft-cited studies may not be representative of the northern Great Plains. There are few published examples of community-wide studies of cowbird parasitism in the northern Great Plains (e.g., Granfors et al. 2001; Woolfenden et al. 2004). Rather, most reports of cowbird parasitism from this region focus on a single species (e.g., Linz and Bolin 1982), a subset of species (e.g., Winter et al. 2004), or species that have evolved defenses against cowbird parasitism (Sealy 1996).

At the continental level, cowbird abundance declines with distance from the center of the species' breeding range in the northern Great Plains (Thompson et al. 2000). The frequencies of cowbird parasitism appear to follow a similar biogeographical pattern (e.g., Smith and Myers-Smith 1998), especially for grassland birds (Jensen and Cully 2005a, 2005b), although this relationship may not be generalized across habitats (Robinson and Smith 2000) and may not be indicative of parasitism frequencies at the local level (Chace et al. 2005). Nonetheless, Chace et al. (2005) acknowl-

edged that, at the continental scale, cowbird abundance appears to be a reasonable predictor of cowbird parasitism levels. Because of the difficulty in obtaining data on both cowbird abundance and brood parasitism across the continent (or even over a large region), there are few examples of studies that have evaluated this relationship using cowbird and nest data collected concurrently at the same study sites over a large region (e.g., Robinson et al. 2000; Jensen and Cully 2005a, 2005b). Only a few evaluations of this biogeographical relationship have included data from study sites in the northern Great Plains (e.g., Smith and Myers-Smith 1998; Herkert et al. 2003).

At local and regional scales, geographic differences in cowbird distribution and abundance also may result from differences in avian communities (e.g., Farmer 1999; Thompson et al. 2000). That is, given that cowbirds are host generalists, measures of avian abundance or richness might serve as proximate cues for cowbirds in determining where to settle (McGeen 1972; Farmer 1999). Chace et al. (2005) listed four nested levels of an avian community that cowbirds could use as cues for settlement: (1) all breeding birds in the avian community, (2) all passerine species, (3) all host species, and (4) a single host species. Very few studies have evaluated this relationship at all four levels (Farmer 1999). Using BBS (Breeding Bird Survey) data, Hahn and O'Connor (2002) concluded that cowbird distribution was not simply the result of shared habitat preferences with their hosts, but rather host abundance was an important predictor of cowbird occurrence in recently colonized regions of the United States (i.e., eastern and western states) and to a lesser extent in the cowbird's ancestral range (i.e., central Great Plains). Except for Hahn and O'Connor's (2002) evaluation using BBS data, the influences of avian abundance and richness on cowbird distribution and abundance have not been evaluated using regional data from the northern Great Plains (reviewed in Chace et al. 2005).

In this paper, we report cowbird densities and parasitism frequencies during two breeding-bird studies in the northern Great Plains: a statewide study in North Dakota (1992 and 1993: Igl and Johnson 1997; Igl et al. 1999) and a Conservation Reserve Program (CRP) grassland study in nine counties of four states (1990–2006: Johnson and Schwartz 1993a, 1993b; Igl and Johnson 1995, 1999; Johnson and Igl 1995, 2001). We use data from nests found incidentally during both studies to examine weekly and annual variation in parasitism rates in the northern Great Plains, and nest data from the CRP grassland study to examine regional variation in parasitism rates. We use data from the long-term CRP grassland study to evaluate the relationships between female cowbird densities and cowbird parasitism and between female cowbird densities and avian densities and richness in different regions of the northern Great Plains. CRP grasslands are a suitable habitat to evaluate these relationships because this habitat has been shown to be a dominant landscape predictor of cowbird distribution in the United States (Hahn and O'Connor 2002).

Study Areas

North Dakota statewide study

The study area for the North Dakota statewide study was described in detail by Stewart and Kantrud (1972) and Igl and Johnson (1997) and is only briefly described here. North Dakota was divided into eight major strata based on biogeographical, physiographical, and ecological characteristics. From these eight strata, 130 quarter-sections (about 64.75 ha each) were selected randomly (Figure 1). The number of sample units allocated to each stratum was proportional to the area of the stratum. Landowners denied access to one quarter-section in 1992 and a different quarter-section in 1993.

CRP grassland study

The CRP study is an ongoing investigation (1990 to present) that is examining breeding-bird communities annually in nearly 350 CRP grassland fields in nine counties of four states (Figure 2), including Fallon and Sheridan counties in Montana; Hettinger, Kidder, and Eddy counties in North Dakota; Butte, McPherson, and Day counties in South Dakota; and Grant County in Minnesota (Johnson and Schwartz 1993a, 1993b). Field size varied from <1.0 to 111.7 ha. In the northern Great Plains, most CRP land was planted to a mixture of native and/or non-native grasses and legumes (Johnson and Schwartz 1993a). Woody vegetation has encroached into some idle CRP fields, and some CRP fields contain wetlands or were partially inundated by water during a recent wet period (Igl 2001; Igl and Johnson, unpublished data).

Methods

Breeding bird and cowbird surveys

In both studies, we conducted total area counts of breeding birds using the strip-transect procedure employed by Stewart and Kantrud (1972; also see Igl and Johnson 1997). During the North Dakota statewide study, bird surveys were conducted by two observers on foot, and each observer surveyed cowbirds and other breeding birds on a rectangular half (805 * 402 m; 32.37 ha) of a quarter-section by following a standardized survey route. This route was 100 m inside of, and parallel to, the boundary of the rectangle. The rectangular halves were usually surveyed simultaneously, and an interval of 400 m was maintained between observers. Deviations of up to 100 m from the route were often necessary to adequately survey all habitats.

Bird species were identified by sight or sound. Counts during precipitation and strong winds (> 24 km/h) were avoided. Surveys of open country birds were conducted between 0.5 h after sunrise and 15:00 CST. Although some surveys occurred outside the time of

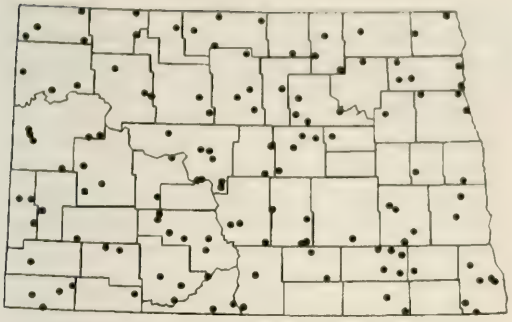

FIGURE 1. Distribution of 130 quarter-sections (64.75 ha each) in North Dakota in which bird surveys were conducted during the breeding seasons in 1992 and 1993.

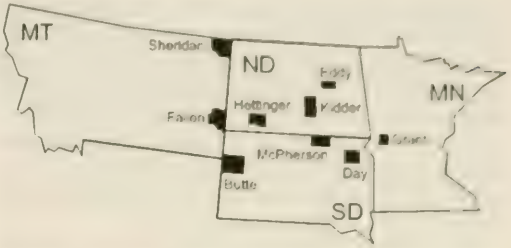

FIGURE 2. Counties in which Conservation Reserve Program grassland fields were surveyed for breeding birds in North Dakota, South Dakota, Minnesota, and Montana, 1990–2006.

most active bird vocalizations (i.e., early morning or late evening), Stewart and Kantrud (1972) concluded that singing and other activities of open-country birds were not appreciably affected by time of day (also see Vickery 1995*). Quarter-sections containing extensive woodland habitats were usually covered on relatively calm (<8 km/h), sunny days between 0.5 h after sunrise and 10:00 CST. These limitations were necessary because song frequencies and other activities of most woodland birds are reduced on cloudy days, in moderate or high winds, and at mid-day.

Counts of breeding birds were based primarily on the number of indicated breeding pairs on territories or home ranges during peak breeding periods. All sample units were surveyed for early-nesting species between 24 April and 7 June, for mid-nesting species between 14 May and 10 July, and for late-nesting species between 22 May and 21 July. When a survey was conducted during an overlapping portion of the peak breeding periods, counts of early-, mid-, and late-nesting species coincided. Thus, quarter-sections that were visited between 22 May and 7 June were only surveyed once, and those that were surveyed before 22 May were surveyed again after 7 June so as to include species from all three breeding periods. For most species, nearly all indicated pairs were observed as segregated pairs or as territorial males. For the sexually dimorphic Brown-headed Cowbird, we separately tallied the males and females seen per sample unit; herein, we report only female cowbird densities. We did not consider certain birds observed during the censuses to be breeding and excluded them from our results. These included late-migrating flocks and other birds passing overhead in high, direct flight. By counting birds only during their peak breeding periods, we maximized the potential for recording breeding birds and, at the same time, minimized the likelihood of confounding breeding birds with migrants.

In the CRP study, total area counts of breeding birds were conducted by using a minor modification of the strip-transect procedures used by Stewart and Kantrud (1972) and Igl and Johnson (1997). Small fields usually were surveyed by a single observer; large fields typically were surveyed by two observers on foot, each simultaneously covering about one-half of the field. The number and configuration of transects were consistent among years but varied depending upon the field size and shape to achieve total coverage of a field. We surveyed each CRP grassland field once each year between 21 May and 9 July in 1990–2006.

Nests and cowbird parasitism

Prior to entering the field in each year, the observers were trained in bird, nest, and egg identification. Nests were found serendipitously during breeding bird surveys and related research activities. Most nests were found by unintentionally flushing an adult host (or rarely a female cowbird) from the nest or nest vicinity. The remainder of the nests were found by observers as they were simply walking through a habitat. When a nest was located, we inspected it and recorded the species (based on the identification of the flushing adult, the nest, or the nest contents) and the number of eggs or nestlings of the host and of cowbirds. If the nest species could not be identified at the time of the initial observation, the nest location was temporarily marked and then revisited and identified at the end of the survey by an experienced observer. We classified a nest as parasitized if it contained at least one cowbird egg or nestling, regardless of the stage of the nesting cycle. Cowbird and host nestlings were identified based on size, gape and flange colors, and down or contour feather characteristics and development. We were unable to return to nests to monitor their outcome or to document additional brood parasitism. We rarely located or checked the contents of nests of upper-canopy nesting species. Most of the nests that we located were found in the egg-laying stage or the incubation stage (see below); cowbirds lay most of their eggs before or during the hosts' egg-laying stage (Johnsgard 1997). Although we found many nests in the nest-building stage (i.e., before the onset of egg laying), we summarize here only active nests, which we defined as nests attended by adults that contained at least one host or cowbird egg and/or nestling. We also

found a few abandoned nests that contained cowbird eggs, but these are not reported because cowbirds are known to parasitize inactive nests (Freeman et al. 1990). The presence of cowbird fledglings that were fed by adult hosts also was noted during the surveys of breeding birds, although an observation of a potential host feeding a cowbird fledgling does not establish conclusively the true foster-parentage of the fledgling cowbird (sensu Klein and Rosenberg 1986).

We use the frequency (%) of nests parasitized as an index to the levels of parasitism. We define the frequency (%) of cowbird parasitism as the total number of parasitized nests (*100) divided by the total number of active nests found for a given species, group of species (e.g., grassland birds), county, or time period (week or year). We define the frequency (%) of multiple parasitism as the total number of nests containing more than one cowbird egg (*100) divided by the total number of parasitized nests found for a given species, group of species, county, or time period. The average (± SD) number of cowbird eggs per parasitized nest (i.e., parasitism intensity) was calculated by summing the number of cowbird eggs found in all parasitized nests in both studies and dividing by the total number of parasitized nests. Although cowbirds may avoid parasitizing nests of ejector species (Sealy and Bazin 1995), we include nests of all passerine species, because ejector species are sometimes parasitized (e.g., Scott 1977; Peer et al. 2000), because parasitism of ejector species may vary geographically (e.g., Haas and Haas 1998) or with time of sympatry with cowbirds (Briskie et al. 1992), and because it is difficult to estimate how often ejector species are parasitized (e.g., Scott 1977). To evaluate changes in cowbird parasitism within the breeding season, we divided each month into four, roughly weekly, periods (7, 8, 7[8] and 8 days, respectively) (sensu Orians et al. 1989). For discussion purposes, we grouped rates of parasitism and multiple parasitism into five categories: low (<10%), low-to-moderate (10–20%), moderate (20–40%), moderate-to-heavy (40–50%), and heavy (>50%) (sensu Ortega 1998: 184). Scientific names of potential host species are included in Table 2.

To determine whether cowbirds avoid laying eggs in previously parasitized nests (Mayfield 1965a; Orians et al. 1989), we evaluated the distribution pattern of cowbird eggs (i.e., random or non-random) using a zero-truncated Poisson distribution model for only parasitized nests (Lindsey 1997). A random distribution of cowbirds eggs suggests that female cowbirds did not discriminate among parasitized nests and that the proportion of nests with 1, 2, 3, 4, …, i cowbird eggs approximated a Poisson distribution (Orians et al. 1989). A non-random distribution of cowbird eggs indicated that the random distribution model was rejected ($P < 0.01$).

For both studies, we calculated overall parasitism frequencies, mean densities of female cowbirds, mean avian densities, and mean avian richness. For the CRP grassland study, we calculated mean avian density and richness among five groups (all of which excluded cowbirds): (1) all avian species, (2) all passerine species, (3) all passerines known to have raised cowbird young (Ortega 1998; Davis and Sealy 2000), (4) all passerines excluding ejectors (Peer and Sealy 2004), and (5) a single, preferred host (i.e., Red-winged Blackbird; see below). We were interested in the regional avian influences that affect cowbird distribution and abundance rather than short-term influences, and thus we averaged across the 17 years within a county and did not analyze the survey data separately for individual years. For the CRP grassland study, we used female cowbird densities both as an explanatory variable in relation to rates of cowbird parasitism and as a response variable in relation to avian community variables (i.e., density and richness). Linear regression analyses (PROC REG; SAS Institute, Inc. 2004) were performed (1) to determine the relationship between overall cowbird parasitism and female cowbird densities, and (2) to examine the relationship between female cowbird densities and the five levels of the avian community.

Results

In the North Dakota study, we observed 160 breeding bird species, including 78 nonpasserine species and 82 passerine species (Igl and Johnson 1997). Given that grasslands, croplands, and wetlands are the three most common habitats in North Dakota (Igl and Johnson 1997), most of the common breeding bird species in North Dakota are associated with such open habitats. The five most abundant species in the North Dakota study, in decreasing order of abundance, were the Horned Lark, Chestnut-collared Longspur, Red-winged Blackbird, Western Meadowlark, and Lark Bunting (scientific names given in Table 2). Average breeding bird densities in a quarter-section, excluding cowbirds, were 126 breeding pairs per 100 ha in 1992 and 143.9 breeding pairs per 100 ha in 1993 (Table 1). The average numbers of species observed in a quarter-section (64.75 ha) were 18.5 species in 1992 and 21.6 species in 1993. Average cowbird densities were 3.0 female cowbirds per 100 ha in 1992 and 4.3 female cowbirds per 100 ha in 1993. Female Brown-headed Cowbirds were found in 66.7 and 76.7% of the quarter-sections in 1992 and 1993, respectively.

In the CRP grassland study, we observed 143 breeding bird species, including 78 nonpasserine species and 65 passerine species. The five most abundant species, in decreasing order of abundance, were Savannah Sparrow, Grasshopper Sparrow, Red-winged Blackbird, Clay-colored Sparrow, and Western Meadowlark. Average breeding-bird densities within a county (averaged across years and excluding cowbirds) ranged from 104.1 to 208.1 breeding pairs per 100 ha, and the average number of species observed within a county ranged from 26.8 to 52.7 species (Table 1). Average cowbird densities within a county ranged from 0.6 to 8.0 female cowbirds per 100 ha, and the average annual

TABLE 1. Summary of Brown-headed Cowbird densities (females/100 ha), cowbird occurrence, breeding bird density (all species excluding cowbirds; breeding pairs/100 ha), and number of breeding bird species per quarter section in two studies in the northern Great Plains, 1990-2006.

frequency of female cowbird occurrence ranged from 12.4 to 54.1%. Average cowbird densities and frequencies were lowest in the counties on the eastern and western edges of our study area (Table 1, Figure 2). This pattern mirrors cowbird distribution maps from the North American BBS (Price et al. 1995; Sauer et al. 2005*), which show cowbird abundance declining both east and west of central North Dakota and South Dakota.

We found 351 active nests of 51 species (18 nonpasserine and 33 passerine species) during the North Dakota statewide study and 2298 active nests of 62 species (23 nonpasserine and 39 passerine species) during the CRP grassland study, for a total of 2649 nests of 75 species (Table 2). Most of the nests of nonpasserine species were found during the egg-laying or incubation stages; 89.9% of the 746 nests of nonpasserine species contained only eggs, and 10.1% contained only nestlings or both eggs and nestlings. Only one nonpasserine nest was parasitized by a cowbird (Table 2). An Upland Sandpiper nest with four sandpiper eggs and one cowbird egg was found in a CRP grassland field in Sheridan County, Montana, on 28 June 1993. Hereafter, we summarize data only for passerine nests.

Most of the active nests of passerines were found during the egg-laying or incubation stages; 85.8% of the 1902 passerine nests contained only eggs, and 14.2% of the nests contained only nestlings or both eggs and nestlings. Overall, the parasitism rate of passerine nests was moderate; 476 of the 1902 (25%) passerine nests that we found during the two studies were parasitized by cowbirds (Table 2).

Twenty-four of the 45 passerine species were found parasitized (Table 2). Among species with 25 or more nests, parasitism levels were low for Western Kingbird (0%), Eastern Kingbird (1.7%), Brown Thrasher (3.8%), Savannah Sparrow (9.8%), Chestnut-collared Longspur (7.7%), and Common Grackle (1.1%); low-to-moderate for Horned Lark (15.6%), Clay-colored Sparrow (11.7%), Lark Bunting (19.4%), Grasshopper Sparrow (19.7%), Bobolink (19.2%), and Western Meadowlark (16.1%); moderate for Brewer's Blackbird (33.3%); and moderate-to-heavy for Red-winged Blackbird (43.1%). The Red-winged Blackbird was the most commonly parasitized species in the two studies (71.2% of all cases of parasitism), and we classified it as a preferred host in subsequent analyses.

Parasitized passerine nests contained from zero to six host eggs and/or nestlings and from one to eight cowbird eggs and/or nestlings (Table 3). Of the 476 parasitized passerine nests, 50.6% contained one cowbird egg, 28.6% contained two, 12.0% contained three, and 8.8% contained four or more cowbird eggs. The maximum number of eggs or nestlings in a parasitized nest (host and cowbird combined) was nine. The average number of cowbird eggs per parasitized nest was 1.9 ± 1.2 (Tables 2 and 3). Multiple parasitism occurred at 12.4% of all passerine nests and at 49.4% of all parasitized passerine nests. Parasitized nests of 18 passerine species contained multiple cowbird eggs and/or nestlings (Table 2). Among parasitized species with 25 or more nests, multiple parasitism rates were low for Eastern Kingbird (0%), Brown Thrasher (0%), and Common Grackle (0%); moderate-to-heavy for Clay-colored Sparrow (43.5%), Lark Bunting (38.9%), Grasshopper Sparrow (44.4%), Chestnut-collared Longspur (50.0%), and Red-winged Blackbird (49.6%); and heavy for Horned Lark (80.0%), Savannah Sparrow (62.5%), Bobolink (53.3%), Western Meadowlark (100%), and Brewer's Blackbird (58.3%). Among these species, the average number of cowbird eggs per parasitized nest was highest for the Western Meadowlark (3.4 ± 1.6); all nine parasitized nests of the Western Meadowlark contained two or more cowbird eggs.

[a] Species known to eject cowbird eggs are identified with "‡". Ejection status is based on information provided in Peer and Sealy (2004).

[b] Breeding habitat associations of passerine species defined as: GRAS: Grassland; WETL: Wetland; WOOD: Woodland; SHRU: Shrubland; OPTR: Open habitat with scattered trees or shrubs; OPWO: Open or semi-open deciduous woodland and edge; RESI: Residential (rural development, urban, human-made structures). Categories follow Igl and Johnson (1997).

[c] Number of nests parasitized / number of nests found.

[d] The overall frequency (%) of cowbird parasitism is the total number of parasitized nests (*100) divided by the total number of nests found (North Dakota statewide study and the CRP grassland study combined). The maximum number of cowbird eggs represents the greatest number of cowbird eggs found in a single nest of that species during both studies combined.

[e] The overall frequency (%) of multiple parasitism is the total number of nests containing more than one cowbird egg (*100) divided by the total number of parasitized nests found (North Dakota statewide study and the CRP grassland study combined). The average number of cowbird eggs per parasitized nest (± SD) is the sum of all individual cowbird eggs found in all parasitized nests in both studies divided by the total number of parasitized nests.

[f] Nonpasserine species (n = no. nests) include: Pied-billed Grebe (*Podilymbus podiceps*, n = 1), Red-necked Grebe (*Podiceps grisegena*; n = 1), American Bittern (*Botaurus lentiginosus*; n = 6), Canada Goose (*Branta canadensis*; n = 1), Gadwall (*Anas strepera*; n = 113), American Wigeon (*Anas americana*; n = 12), Mallard (*Anas platyrhynchos*, n = 123), Blue-winged Teal (*Anas discors*; n = 65), Northern Shoveler (*Anas clypeata*; n = 12), Northern Pintail (*Anas acuta*; n = 29), Canvasback (*Aythya valisineria*, n = 1), Redhead (*Aythya americana*; n = 3), Ring-necked Duck (*Aythya collaris*; n = 1), Lesser Scaup (*Aythya affinis*; n = 5), Northern Harrier (*Circus cyaneus*; n = 48), Swainson's Hawk (*Buteo swainsoni*, n = 3), Ferruginous Hawk (*Buteo regalis*; n = 2), Ring-necked Pheasant (*Phasianus colchicus*; n = 35), Sharp-tailed Grouse (*Tympanuchus phasianellus*, n = 14), Wild Turkey (*Meleagris gallopavo*; n = 1), Sora (*Porzana carolina*; n = 2), American Coot (*Fulica americana*; n = 10), American Avocet (*Recurvirostra americana*, n = 1), Upland Sandpiper (*Bartramia longicauda*; n = 7), Wilson's Snipe (*Gallinago delicata*; n = 2), Wilson's Phalarope (*Phalaropus tricolor*; n = 5), Mourning Dove (*Zenaida macroura*, n = 233), Black-billed Cuckoo (*Coccyzus erythropthalmus*; n = 2), Short-eared Owl (*Asio flammeus*; n = 5), and Common Nighthawk (*Chordeiles minor*; n = 4).

Mean ± SE	111.8 ± 17.2	22.6 ± 2.1	46.9 ± 3.8		

[a]Mean number of cowbird eggs or nestlings per parasitized nest.
[b]Random distribution of cowbird eggs in parasitized nests was evaluated using a zero-truncated Poisson distribution model (Lindsey 1997). Random distribution of cowbirds eggs indicated that female cowbirds did not discriminate among parasitized nests and that the proportion of nests with 1, 2, 3, 4, ...*i* cowbird eggs approximated a Poisson distribution. Non-random distribution indicated that the random distribution model was rejected ($P < 0.01$).
[c]Data for the North Dakota statewide study and the CRP study were combined for 1992 and 1993.

Not including nests of the Red-winged Blackbird, our sample of passerine nests from the two studies included mostly nests of grassland-nesting (e.g., Western Meadowlark) and edge-nesting (e.g., Yellow Warbler) species and very few nests of cavity-nesting (e.g., House Wren) or woodland-interior (e.g., Ovenbird) species (Table 2). We found 482 nests of 15 passerine species that typically nest in grasslands. Overall, the parasitism rate of grassland bird nests was low-to-moderate (16.4%). We found 602 nests of 23 passerine species that typically nest in habitats characterized by woody vegetation (i.e., woodland, shrubland, open habitat with scattered trees or shrubs, open or semi-open deciduous woodland, and edge). The parasitism rate of bird species associated with woody vegetation was low (9.5%).

Of the 45 passerine species for which nests were found, nine species are known to eject cowbird eggs (Table 2; Peer and Sealy 2004). Of the 257 nests of these nine ejector species that we found, 12 (4.7%) contained cowbird eggs. The overall parasitism rate for nests of all non-ejector (i.e., acceptor) passerine species combined was 28.2% ($n = 1645$). In addition, Yellow Warblers often bury the contents of parasitized nests under a new nest floor (Clark and Robertson 1981; Burgham and Picman 1989). Eight of 24 (33.3%) Yel-

[a]To evaluate changes in cowbird parasitism within the breeding season, each month was divided into four, roughly weekly, periods (week I = 7 days, week II = 8 days, week III = 7[8] days, and week IV = 8 days) (sensu Orians et al. 1989).
[b]See Table 4 for explanation.
[c]Mean includes third week in May to third week in July (i.e., weeks with cowbird parasitism).

low Warbler nests each contained a single cowbird egg. During the CRP study, buried (but visible) cowbird eggs were observed in two Yellow Warbler nests (one in Kidder County, North Dakota, on 27 June 2003 and one in Eddy County, North Dakota, on 25 June 2005) and one Clay-colored Sparrow nest (McPherson County, South Dakota, on 13 June 2006).

Parasitized nests of passerines were found in 16 of the 17 years (Table 4). No parasitized nests were found in 1996, which also is the year that we found the fewest number of active passerine nests. Excluding 1996, annual parasitism rates ranged from 12.7 to 35.7% and averaged 22.6% (Table 4). The average annual rate of multiple parasitism was 46.9%. The zero-truncated Poisson distribution model for parasitized nests was rejected in one (i.e., 2005) of the 16 years in which parasitized nests were found.

In both studies combined, passerine nests were found in 11 of 12 weekly periods from the last week of April through the third week of July (Table 5). Eleven passerine nests were found in two of the three weeks before the first cowbird egg was found (i.e., before the third week in May), although cowbirds were recorded in each of those three weeks (Igl and Johnson, unpublished data). In the North Dakota statewide study, we found active nests between 27 April and 20 July, parasitized nests between 20 May and 18 July, and multiply parasitized nests between 20 May and 18 July. In the CRP grassland study, we found active nests between 22 May and 9 July, parasitized nests between 29 May and 9 July, and multiply parasitized nests between 29 May and 9 July. During both studies, nonparasitized and parasitized nests were found largely between late May and early July, which corresponds with the peak breeding periods of most passerine species in the northern Great Plains, including the Brown-headed Cowbird (Stewart 1975; Igl and Johnson 1997; Tallman et al. 2002). After the third week in May, weekly parasitism rates ranged from 9.1 to 37.3% and averaged 20.7%; the highest parasitism rates were found in the second and third weeks of June (Table 5). The average weekly rate of multiple parasitism was 54.3%. The zero-truncated Poisson distribution model for parasitized nests was rejected in two (i.e., second and fourth week of June) of eight weekly periods.

In the CRP grassland study, parasitized and multiply parasitized nests of passerines were found in all nine counties (Table 6). Cowbird parasitism of passerine nests was low in Fallon County in southeastern Montana (5.8%) and Grant County in western Minnesota (9.3%). Parasitism rates were low-to-moderate in Butte County in western South Dakota (12.8%) and Sheridan County in northeastern Montana (11.6%), and moderate in Hettinger (29.9%), Kidder (25.3%), and Eddy (23.8%) counties in North Dakota and Day County in northeastern South Dakota (28.9%). Heavy parasitism was found in McPherson County in north-central South Dakota (51.5%). The frequency of multiple parasitism was moderate in Butte (21.4%) and Day counties in South Dakota (39.8%) and Fallon County, Montana (25%), and moderate-to-heavy to heavy in the other six counties (range: 42.9–58.7%). The zero-truncated Poisson distribution model for parasitized nests was rejected in one (i.e., Day County, South Dakota) of the nine counties (Table 6). Nests within the counties of highest female cowbird abundance experienced higher frequencies of cowbird parasitism ($R^2 = 0.64$, $F = 12.65$, $P = 0.0093$) than those found in counties with the lowest female cowbird abundance (Figure 3). The quadratic term for cowbird densities was nonsignificant ($P = 0.62$) and was not included in the final model.

TABLE 6. Regional variation in Brown-headed Cowbird parasitism in passerine nests (all species combined) found incidentally during breeding bird surveys in Conservation Reserve Program grassland fields in nine counties in the northern Great Plains, 1990–2006.

County	Total number of nests	Frequency of cowbird parasitism (%)	Frequency of multiple parasitism (%)	Parasitism intensity (mean ± SD)[a]	Distribution of cowbird eggs in parasitized nests[a]
Butte, South Dakota	109	12.8	21.4	1.2 ± 0.4	random
Day, South Dakota	322	28.9	39.8	1.6 ± 1.1	non-random
Eddy, North Dakota	172	23.8	46.3	1.8 ± 1.1	random
Fallon, Montana	69	5.8	25.0	1.3 ± 0.5	random
Grant, Minnesota	151	9.3	42.9	1.5 ± 0.7	random
Hettinger, North Dakota	211	29.9	58.7	2.2 ± 1.5	random
Kidder, North Dakota	332	25.3	45.2	1.7 ± 0.9	random
McPherson, South Dakota	233	51.5	59.2	2.0 ± 1.1	random
Sheridan, Montana	69	11.6	50.0	2.1 ± 1.3	random

[a]See Table 4 for explanation.

In the CRP grassland study, cowbird densities, total breeding bird densities, and total breeding bird richness were lowest in the southwestern counties (Butte County, South Dakota, and Fallon County, Montana) and highest in counties near the center of the cowbird's breeding bird range. There was a positive relationship between female cowbird densities and all measures of avian abundance and richness. That is, female cowbird densities increased with increasing density and richness at all levels of the avian community (Table 7). Breeding bird density for all bird species ($R^2 = 0.72$) was a better predictor of cowbird abundance than the other four levels of avian densities (Table 7, Figure 4a). Breeding bird richness for all bird species ($R^2 = 0.69$) was a better predictor of cowbird abundance than the other three levels of avian richness (Table 7, Figure 4b). There was only a weak suggestion that cowbirds use, as a settlement cue, the number of passerines species known to have raised cowbird young ($P = 0.115$).

During breeding bird surveys in both studies, observers noted 586 instances of adult passerines provisioning food to individual fledglings, of which only 26 (4.4%) instances involved hosts feeding cowbird fledglings. These 26 observations occurred between 4 June and 7 July and involved eight host species: Clay-colored Sparrow (5 cases), Grasshopper Sparrow (1 case), Le Conte's Sparrow (1 case), Savannah Sparrow (6 cases), Song Sparrow (4 cases), Brewer's Blackbird (2 cases), Red-winged Blackbird (5 cases), and Orchard Oriole (2 cases). These eight species accounted for 83.6% of the total cowbird parasitism in these two studies (Table 2). Although we cannot establish conclusively the true foster-parentage of these fledgling cowbirds, we did not observe any non-parasitized species (i.e., species whose nests were not parasitized during the two studies) feeding cowbird fledglings during the two studies.

Discussion

Brown-headed Cowbirds parasitize nests of a wide variety of host species (Friedmann 1963; Lowther 1993), including some inappropriate hosts. As in other studies (Ortega 1998), we found almost no cowbird parasitism of nonpasserine nests. Most nonpasserines are considered unsuitable hosts, and their nests usually are avoided by Brown-headed Cowbirds (Rothstein and Robinson 1998). Although the only parasitized nonpasserine, an Upland Sandpiper, was clearly an unsuitable host (i.e., a large-bodied host with precocial, nidifugous young), several other studies have documented cowbird eggs in Upland Sandpiper nests (Higgins and Kirsch 1975; Faanes and Lingle 1995*; Davis and Duncan 1999).

Our overall frequency of cowbird parasitism (25%) for passerine species was within the range that Ortega (1998) considered moderate (20–40%). This overall rate seems low given that cowbird densities are highest in the northern Great Plains (Sauer et al. 2005*) and that cowbirds are more abundant than many of their common hosts in this region (Igl and Johnson 1997; Igl et al. 1999). However, our combined parasitism rate is based on nests from two studies, an extensive region, 17 years, and numerous passerine species, including several species that ostensibly have developed behavioral defenses against cowbird parasitism (see below). After we excluded nests of ejector species, our overall parasitism rate remained moderate (28.2%). Some studies in this region have found higher combined rates of cowbird parasitism than those reported herein. For example, Koford et al. (2000) found an overall parasitism rate of 40.3% for passerines nesting in seeded and native grasslands and cropland in North Dakota and Minnesota, and Davis and Sealy (2000) found an overall rate of 32.6% for species nesting in grasslands in southwestern Manitoba. In both of these studies, some individual species experienced moderate-to-heavy levels of cowbird parasitism (e.g., >40% parasitism for Western Meadowlarks in both studies). Robinson and Smith (2000) suggested that some of these commonly cited reports of high parasitism rates from the northern Great Plains might not be representative of this region. Indeed, some recent reviews of geographic patterns of cowbird parasitism (e.g., Peer et al. 2000; Chace et al. 2005) focused on the extreme

FIGURE 4. Relationship between (a) mean female cowbird densities and average densities of all other breeding bird species, and (b) mean female cowbird densities and mean species richness within the breeding bird community (excluding cowbirds) in Conservation Reserve Program (CRP) grasslands in North Dakota, South Dakota, Minnesota, and Montana, 1990–2006. The circle in Figure 4a indicates a potential outlier, Grant County in Minnesota, which is discussed in the text.

cases of parasitism in the northern Great Plains (e.g., Linz and Bolin 1982; Davis and Sealy 2000; Koford et al. 2000). There are many less-cited studies of cowbird parasitism (see Shaffer et al. 2003) with low-to-moderate rates of cowbird parasitism in this region (e.g., Hill and Sealy 1994; Granfors et al. 2001; Davis 2003; Woolfenden et al. 2004). For example, in Manitoba, Davis (2003) found an overall parasitism rate of 19.9% for six grassland species in southern Saskatchewan over a 5-year period.

Although our overall rate of cowbird parasitism was 25%, we did find higher rates of parasitism in some years (e.g., 35.7% in 2001), weeks (e.g., 37.3% in the second week of June), counties (e.g., 51.5% in McPherson County, South Dakota), and individual species (e.g., 43.1% for the Red-winged Blackbird). The results from our studies can serve as a reminder that cowbird parasitism rates are not constant across space or time (i.e., among years or within a breeding season) and that cowbirds differentially parasitize hosts within the same habitats. Differences in parasitism levels among studies in the northern Great Plains may simply reflect variation among species, regions, habitats, or years. For example, Davis and Sealy's (2000) overall parasitism rate of 32.6% was based on data collected at three study sites over two years; parasitism rates were low-to-moderate at two of the study sites (18 and 20%) and heavy at the third study site (67%). We echo Hahn and Hatfield's (1995) caveat that patterns of cowbird parasitism are complex and variable, and that field studies of cowbird parasitism would be more effective if they were long-term, community-wide studies set in strategically chosen communities in different regions.

Our nest data were slightly unorthodox compared to nest data from many other studies. We located all of our nests fortuitously and observed each nest only once. Any cowbird eggs ejected before our surveys, any nests abandoned before our surveys, any cowbird eggs buried completely in the nest lining, and any cowbird eggs added or removed after our brief observations were not recorded in our studies, and thus our frequencies of cowbird parasitism should be considered minimal estimates. These limitations, however, are not unique to our data but rather are common features of all studies of cowbird parasitism that do not involve cameras, because most nests are not monitored continuously throughout the nesting cycle but rather are visited at relatively fixed intervals (e.g., every 2–4 days) for relatively brief periods of time (e.g., less than a few minutes). Even systematic nest searches are neither incessant nor comprehensive, but rather occur at fixed intervals (e.g., Koford et al. 2000; Davis 2003; Winter

TABLE 7. Five levels of avian abundance (density) and richness (number of species) that female Brown-headed Cowbirds could use as proximate cues for settlement in Conservation Reserve Program grassland fields in nine counties in the northern Great Plains, 1990–2006. Linear regression analyses were performed to examine the relationship between female cowbird densities and each different subset of avian abundance and richness at the five levels of the avian community (also see Figure 4).

Level of avian community[a]	Breeding bird density			Number of breeding species		
	R^2	F	*P*	R^2	F	*P*
All breeding birds	0.72	17.53	0.004	0.69	15.56	0.006
All passerines	0.63	12.02	0.011	0.40	4.65	0.068
All passerines that have raised cowbirds	0.66	13.64	0.008	0.32	3.25	0.115
All passerines that are non-ejectors	0.62	11.39	0.012	0.38	4.32	0.076
Preferred host (Red-winged Blackbird)	0.54	8.35	0.023	–	–	–

[a] Excluding cowbirds.

et al. 2004). In addition, many studies that use systematic nest searches also include a fortuitous component to their nest searching methodology (e.g., Koford et al. 2000; Davis 2003). Thus, nearly all estimates of cowbird parasitism in the literature could be considered minimal estimates.

In our two studies, female cowbirds did not avoid laying eggs in previously parasitized nests. Nearly one-half of the parasitized nests in our two studies contained more than one cowbird egg, with the average parasitized nest containing about two cowbird eggs. The assumption that female cowbirds laid eggs randomly in parasitized nests could only be rejected in two of eight weekly periods, one of 16 years, and one of nine counties in the CRP grassland study. Deviations from a random Poisson distribution were likely related to a greater number of nests with multiple cowbird eggs or nestlings than would be expected by chance. Multiple parasitism has been widely documented in nests parasitized by the Brown-headed Cowbird (McLaren et al. 2003). Although multiple parasitism can vary by region or host species, it typically occurs in about one-third of all reported cases of cowbird parasitism (Friedmann 1963; Lowther 1993; Johnsgard 1997; Ortega 1998) and seems to be more common in nests of larger hosts (Lorenzana and Sealy 1999; Trine 2000). Little is known about the factors that might influence multiple parasitism, but some mechanisms have been proposed or investigated. For example, multiple parasitism might occur if (1) a female cowbird exhibits host preference (Smith and Myers-Smith 1998), (2) there is a high ratio of female cowbirds to host nests (McGeen 1972), (3) there is a shortage of alternative host nests (Smith and Myers-Smith 1998), or (4) an inexperienced and nonselective female makes a poor host choice (McLaren et al. 2003). Cowbird hosts in the Great Plains seem to be particularly vulnerable to multiple parasitism (e.g., Elliott 1978; Davis and Sealy 2000; this study), which may reflect higher densities of cowbirds (Elliott 1977; Ortega 1998) or lower densities of available or suitable hosts (Robinson and Smith 2000).

We likely underestimated the frequency of cowbird parasitism of those species that eject or bury cowbird eggs or that abandon parasitized nests (Ortega 1998). Less than 5% of the nests of ejector species in the two studies contained cowbird eggs, which was much lower than the overall parasitism rate (28.2%) for acceptor species. Ejection of cowbird eggs by a host is an effective anti-parasite strategy among some North America passerines (Ortega 1998; Peer and Sealy 2004), especially among edge-nesting passerines that are common in the northern Great Plains (Igl and Johnson 1997; Table 1). Even within acceptor species, however, some individuals are prone to abandon parasitized nests and then re-nest (Lorenzana and Sealy 1999). Hosoi and Rothstein (2000) showed that the frequency of desertion of parasitized nests was higher in non-forest than forest species and suggested that increased nest desertion was an evolved response to cowbird parasitism. Among small-sized hosts, nest desertion seems to be a common response to parasitism or defense against parasitism (Ortega 1998). Many species that breed in the northern Great Plains are known to abandon their nests occasionally as a result of parasitism or cowbird removal of host eggs (e.g., Ortega 1991; Hosoi and Rothstein 2000), including some grassland and shrub-grassland species, although the frequency of abandonment may be quite low (Sealy 1999; Davis and Sealy 2000).

The Red-winged Blackbird was the third most abundant species observed in both of our studies. Despite its aggressive nest-defense behaviors against cowbirds and its colonial-nesting tendencies (Freeman et al. 1990), the Red-winged Blackbird was the most commonly parasitized species in the two studies (43.1% parasitism, 49.6% multiple parasitism, 71.2% of all cases of parasitism) and appears to be a preferred cowbird host in the northern Great Plains. Our data support Hanka's (1979) contention that cowbirds may show a phylogenetic preference for Red-winged Blackbirds and other Icterine species (e.g., Brewer's Blackbird, Orchard Oriole; Table 2) in the cowbird's range. Linz and Bolin (1982) and Koford et al. (2000) reported similar parasitism rates (42 and 43%, respectively) for Red-winged Blackbirds in this region. In the eastern portion of the cowbird's range, Red-winged Blackbirds are rarely parasitized (e.g.,

Hahn and Hatfield 1995). Although we categorized the Red-winged Blackbird as a wetland species (Table 2; Igl and Johnson 1997), many of the red-wing nests that we found during the CRP grassland study were scattered in upland habitats (grassland, shrub-grassland), where group defense is generally lower (Robertson and Norman 1977; Ortega 1991) and parasitism rates are generally higher (Robertson and Norman 1976; Krapu 1978). Several host species are known to avoid or reduce parasitism by acting aggressively toward cowbirds (Robertson and Norman 1976, 1977), but aggression is not always an effective host defense against cowbird parasitism, especially in habitats in which host densities are low because cowbirds may use host aggression (Robertson and Norman 1977) or vocalizations (Clotfelter 1998) to locate nests. Nonetheless, the Red-winged Blackbird is one of a few species reported to reduce parasitism by mobbing (Freeman et al. 1990; Chace et al. 2005).

The presence of Red-winged Blackbirds may be a double-edged sword for other passerines nesting in the same habitats, such as CRP grasslands. Red-winged Blackbirds are conspicuous breeding birds in CRP grasslands and thus might increase parasitism in nests of other species. Barber and Martin (1997) found that a conspicuous, co-occurring species in a breeding bird community can increase the risk of cowbird parasitism on alternative host species. Alternatively, other species may benefit from nesting near Red-winged Blackbirds if (1) the defensive behavior of blackbirds toward cowbirds reduces cowbird activity in the area, or (2) higher cowbird parasitism of blackbird nests reduces parasitism pressure on other species. Fretwell (1972) noted higher rates of cowbird parasitism in Dickcissel nests that were built near Red-winged Blackbird nests, whereas Clark and Robertson (1979) found the opposite for Yellow Warblers. Woolfenden et al. (2004) speculated that Red-winged Blackbirds might have increased the risk of parasitism on Yellow Warblers in their Manitoba study sites. The influence of Red-winged Blackbird presence and abundance on cowbird parasitism rates of other species requires further study.

Mayfield (1965b) suggested that grassland birds may have evolved defenses against brood parasitism because of their long evolutionary history of co-occurrence with the Brown-headed Cowbird in the Great Plains. To date, however, the species that have shown the strongest anti-parasite behaviors (i.e., egg ejection) have not been the grassland species but rather have been the species associated with woody vegetation (Peer and Sealy 2004, Table 2). Our overall rate of cowbird parasitism for grassland bird nests (16.4%) was much lower than those reported in some studies (e.g., Elliott 1978 [57.7%]; Davis and Sealy 2000 [32.6%]; Jensen and Finck 2004 [42.9%]) but comparable to or higher than those reported in other studies (e.g., Strausberger and Ashley 1997 [0%]; Kershner and Bollinger 1998 [1.7%]; Robinson et al. 2000 [7.8%]; Granfors et al. 2001 [14%]; Davis 2003 [19.9%]; Winter et al. 2004 [6.7%]). Nonetheless, we found a higher frequency of parasitism in nests of grassland species than in nests of species that nest in edge and woodland habitats (9.5%). In contrast to our results, in Illinois, Robinson et al. (1999, 2000) and Strausberger and Ashley (1997) found a higher frequency of parasitism in species nesting in edge and woodland habitats than in nests of grassland species. Although the difference between the two regions for grassland birds is consistent with the pattern that cowbird parasitism declines with distance from the center of the cowbird's range in the northern Great Plains, the difference for species associated with woody vegetation is contrary to this generalization. Again, these patterns emphasize the complexity and variability of cowbird parasitism in North America (Hahn and Hatfield 1995). Robinson and Smith (2000) and others (Peer et al. 2000; Jensen and Finck 2004) have suggested that the higher levels of parasitism in grasslands in the Great Plains than those in the Midwest might reflect the near absence of large forested areas, where more tolerant hosts can absorb cowbirds and cowbird parasitism from grasslands. Seemingly, our data support this contention. In our most-forested county in the CRP grassland study (Grant County in west-central Minnesota; Igl and Johnson, unpublished data), the density of female cowbirds (and cowbird parasitism) was much lower than would be expected given the density of breeding birds in the avian community (Figure 4a). Moreover, Minnesota typically is lumped with midwestern states rather than with Great Plains states. In the other eight counties, there are few, if any, large forested areas that could absorb cowbird parasitism from the open grasslands. Trees and shrubs in these eight counties occur largely in small, often linear, patches, where cowbird egg ejectors (e.g., kingbirds, thrashers, catbirds, robins) dominate the breeding bird community. The low parasitism rates of edge and woodland species in our study may reflect the predominance of ejector species in woody habitats in the northern Great Plains (Igl and Johnson 1997) and the avoidance by cowbirds of a habitat that may contain many less-tolerant hosts (Sealy and Bazin 1995).

In Illinois, Peer et al. (2000) recently found that Western Meadowlarks rejected (i.e., ejected or damaged) 78% of artificial and real cowbird eggs experimentally added to nests. In contrast, in the northern Great Plains, some Western Meadowlark populations are moderately to heavily parasitized (23–67%: Davis and Sealy 2000; 19–47%: Koford et al. 2000), and the species often experiences extreme levels of multiple parasitism in this region (Davis and Sealy 2000; Davis 2003; this study). It is unclear why some meadowlark individuals or populations experience heavy or intense parasitism (e.g., average of 3.4 and 3.1 cowbird eggs per parasitized nest in this study and Davis and Sealy 2000, respectively), whereas others apparently experience little or none. Davis and Sealy (2000) suggested that the apparent geographic variation in parasitism levels in Western Meadowlark populations in

the northern Great Plains and elsewhere might reflect differences in the size of suitable grassland patches and the availability of other host species in the community. Peer et al. (2000) suggested that geographic differences in parasitism levels in the northern Great Plains and the Midwest might reflect geographic variation in egg rejection by Western Meadowlarks. Egg rejection behavior in the Western Meadowlark should be tested in more geographic locations or landscapes to resolve these issues. Moreover, the Western Meadowlark and its congener, the Eastern Meadowlark (*Sturnella magna*), use a similar tactic to destroy eggs or clutches of other birds (Creighton and Porter 1974; Schaef and Picman 1988; Picman 1992). The function of this egg-destroying behavior has been speculative (e.g., predation, interference competition for limited resources), but in view of the similarities (e.g., egg removal, puncture) between this egg-destroying behavior at nests of other birds and cowbird egg ejection at their own nests, experiments are needed to evaluate the relationship between general egg destruction and cowbird egg rejection by meadowlarks.

In our CRP grassland study, female cowbird densities varied greatly among the nine counties in the northern Great Plains, and rates of cowbird parasitism were higher in the counties in which densities of female cowbirds were higher. Our results support the interpretation of Miles and Buehler (2000) and Chace et al. (2005) that female cowbird densities are a reasonable predictor of the frequencies of cowbird parasitism. Our results also support the contention that cowbird parasitism declines with distance from the center of the cowbird's range, although on a smaller scale (Hoover and Brittingham 1993; Smith and Myers-Smith 1998; Thompson et al. 2000).

Few studies have evaluated the relationship between cowbird abundance and parasitism levels using cowbird and nest data collected concurrently at the same study sites over a large region (e.g., Robinson et al. 2000; Jensen and Cully 2005a, 2005b). Large-scale evaluations of this relationship typically have relied on data from unconnected sources, such as abundance data from the North American Breeding Bird Survey (BBS) and nest data from the Cornell Laboratory of Ornithology or from multiple studies (e.g., Hoover and Brittingham 1993; Basili 1997; Smith and Myers-Smith 1998; Herkert et al. 2003). Most evaluations of this relationship have focused on single species (Hoover and Brittingham 1993; Basili 1997; Smith and Myers-Smith 1998; Herkert et al. 2003). Nonetheless, many studies have found similar positive relationships between cowbird densities and cowbird parasitism levels. For example, Basili (1997) and Herkert et al. (2003) showed that cowbird densities on BBS routes were positively related to frequencies of cowbird parasitism of Dickcissel nests from multiple studies across several states. Jensen and Cully (2005a,b) found a similar, positive relationship between female cowbird densities and parasitism levels of Dickcissel nests at eight study sites in Kansas and Oklahoma. In a meta-analysis of nest and cowbird data from six studies from four midwestern states, Thompson et al. (2000) similarly found that cowbird abundance and parasitism levels of multiple species were positively correlated across study areas. In contrast, Woolfenden et al. (2004) found that female cowbird abundance was not related to parasitism frequency among three species in an avian community in Manitoba, and Robinson et al. (2000) found that the percentage of nests parasitized was not related to cowbird abundance in multiple forest sites across Illinois.

In CRP grasslands, we also found a positive relationship between cowbird abundance and all five levels of the avian community, including all avian species, all passerine species, all passerines that are non-ejectors, all passerines known to raise cowbird young, and a single, preferred host (i.e., Red-winged Blackbird). The abundance and richness of all avian species were the strongest predictors of cowbird abundance, which suggests that cowbirds might use the overall breeding bird community as a settlement cue for optimal areas to breed rather than more specific passerine or host categories (e.g., all passerines that are known to have raised cowbird young). The number of individuals and the number of species represent different components of a cowbird's breeding resource. The presence of more individuals and more species with different breeding chronologies ensures a larger number of potential hosts within the breeding bird community throughout the cowbird's breeding season (Farmer 1999). Although we evaluated these relationships using only data from the CRP grassland study, cowbirds also might use other cues (e.g., vegetation or landscape factors) as an indicator of the richness or abundance of the avian community (Chace et al. 2005).

Chace et al. (2005) tabulated 16 published studies and one unpublished study that evaluated the relationship between different measures of the avian community and cowbird abundance or occurrence. As with our results, many studies found positive relationships between cowbirds and different measures of avian densities and richness. To our knowledge, Farmer (1999) is the only other published study to have evaluated multiple host and avian community measures using both abundance and richness data. Farmer (1999) found positive relationships for nearly every level of the avian community, including abundance and richness categories. Because host species are necessary for cowbirds to be reproductively successful, most studies have evaluated these relationships at the host level. Results of such evaluations have been inconsistent. Moreover, comparisons among studies using host categories are difficult because a variety of definitions of host communities were used (Chace et al. 2005). For example, Thompson et al. (2000) found that cowbird abundance was significantly correlated with host abundance (i.e., hosts included species that bred on the study area and accepted cowbird eggs), whereas Robinson et al. (2000)

found no relationship between cowbird abundance and host abundance (i.e., hosts included species that accept cowbird eggs regularly but excluding cavity nesters, cowbird egg ejectors, and large species). Evans and Gates (1997) found that cowbird abundance was positively related to the abundance of all avian species combined, but the relationship was non-significant for richness of all avian species and richness and abundance of host species (i.e., known cowbird hosts).

In summary, our data show that, even within the northern Great Plains, there is considerable variation in parasitism rates among species and across space and time. Our results demonstrate that parasitism rates overall are moderate in the northern Great Plains, although some individual species, counties, years, and weeks experience heavier rates of parasitism or multiple parasitism than others. Our study is one of the first to show a strong, positive relationship between regional cowbird abundance and nest parasitism rates using both cowbird abundance and nest data collected at the same study sites. We also found a clear, positive relationship between female cowbird densities and the overall breeding bird communities in CRP grasslands in the northern Great Plains. More studies are needed to determine if these relationships hold elsewhere in the northern Great Plains with different host communities or within other habitats.

Wolf, *Canis lupus*, Behavior in Areas of Frequent Human Activity

Ellen Heilhecker[1], Richard P. Thiel[2], and Wayne Hall, Jr.[2]

[1]University of Wisconsin-Stevens Point, College of Natural Resources, Stevens Point, Wisconsin 54481 USA
[2]Wisconsin Department of Natural Resources, Sandhill Wildlife Area, Box 156, Babcock, Wisconsin 54413 USA

Heilhecker, Ellen, Richard P. Thiel, and Wayne Hall, Jr. Wolf, *Canis lupus*, behavior in areas of frequent human activity. Canadian Field-Naturalist 121(3): 256-260.

We report incidental observations of Wolves (*Canis lupus*) tolerating human activity in central Wisconsin. Three monitored packs raised pups in close proximity to varying levels of human activity. Wolf pups were raised <350m from rearing pens of the endangered Whooping Crane (*Grus americana*), which saw daily human activity. One pack used cornfields as rendezvous sites within 175 m of a maintenance shed visited regularly by workers. Another pack centered their activities along a well-traveled state highway using both the verge and the road center for activity. Aerial locations of 10 yearling and adult dispersing Wolves were plotted to evalute human densities in natal territories relative to dispersal and post-dispersal territories. Township densities ($\bar{\chi}$ = 9.02 humans/km^2, SE = 4.015) and residential densities ($\bar{\chi}$ = 5.59 housing units/km^2, SE = 2.12) in natal pack territories were significantly greater (P <.01) for dispersal and post-dispersal township densities ($\bar{\chi}$ = 43.98 humans/km^2, SE =7.37) and residence densities ($\bar{\chi}$ = 23.12 housing units/km^2, SE =3.49). Furthermore, a pup negotiated the densely populated region of northern Illinois and dispersed from central Wisconsin to east-central Indiana, a distance of at least 690 km. As Wolves live in closer proximity to humans, living in areas of higher township and residential densities, they can be expected to be more habituated to people, increasing the probability of human/Wolf conflicts.

Key Words: Wolf, *Canis lupus*, pups, humans, habituation, behavior, Wisconsin.

Historically, Gray Wolves (*Canis lupus*) were one of the most widely distributed land mammals in North America inhabiting all regions except arid deserts (Young 1944; Mech 1970; Mech and Boitani 2003). However, human settlement and persecution restricted Wolves to northern forested regions and eventually the only substantial population within the lower 48 states occurred in northern Minnesota (Mech 1970).

Under the protection of the federal Endangered Species Act of 1973, Wolves have returned to some areas within their historical range (Mech 1995). They began recolonizing Wisconsin in the mid-1970s (Mech and Nowak 1981; Thiel and Welch 1981; Wydeven et al. 1995). Wolves have since repopulated much of northern Wisconsin and an isolated area in the central part of the state referred to as the Central Forest Region (CFR). In 1999, the Wisconsin Department of Natural Resources (WDNR) downlisted the Wolf from an endangered to a threatened species (WDNR 1999*). Wolves continued to surpass target recovery levels. In April 2003, the U.S. Fish and Wildlife Service proposed to delist the Eastern Distinct Population Segment of Gray Wolf, which includes Wisconsin (Federal Register 2003*).

Wolves initially recolonized areas in Wisconsin with significantly lower road densities ($\bar{\chi}$ = 0.23 km/km^2) and human densities ($\bar{\chi}$ = 1.52 people/ km^2) (Mladenoff et al. 1995). As recovery progresses, Wolves are demonstrating an increasing tolerance to human activity throughout the upper Great Lakes region, including Wisconsin (Thiel et al. 1998). In recent years, Wolves have denned near active sphagnum moss drying sites, occupying homesites inside artillery impact zones on military bases, crossed four lane highways and large expanses of non-forested areas, and bypassed major U.S. cities (Licht and Fritts 1994; Mech et al. 1995; Thiel et al. 1998). While such behavior is not unique to the species, it is unique to Wolves living in the continental United States (McNay 2002; Mech and Boitani 2003). Observations of Wolves displaying increased tolerance towards humans are of value insofar as it affects management of Wolf recovery. This paper reports on the success of Wolves attempting to colonize areas of higher human densities than previously reported in the continental United States.

Study Area and Methods

Wisconsin's Central Forest Region (CFR) encompasses 7767 km^2 of deciduous forest (*Acer saccharum, Tilia americana, Quercus alba, Q. borealis, Q. velutina*), coniferous swamps (*Picea mariana, Larix laricina),* aspen stands (*Populus tremuloides, P. grandidentata*), pine barrens (*Pinus banksiana, P. resinosa, P. strobus*), sphagnum bogs, and marshes (Curtis 1959; Finley 1976*). A 12 141-hectare swamp, the largest in Wisconsin, lies within the CFR (Martin 1965). The CFR includes portions of Eau Claire, Chippewa, Clark, Jackson, Wood, Monroe, Juneau, Adams, and Marquette counties. The majority of the CFR consists of private industrial, county, state and federal forestland. Major economic industries include logging and cranberry agriculture as well as dairy operations (WDNR 2003*). Road density within the CFR is 1.23 km/km^2 (U. S. Census Bureau 2000*; WDNR 2003*).

Wolves were captured on or near rendezvous sites, located by howling and track surveys, using offset,

modified #14 Newhouse traps during summers 2002 and 2003, following guidelines established by Animal Care and Use committees within the Wisconsin Department of Natural Resources and University of Wisconsin-Stevens Point. With the exception of setting traps, researchers minimized time spent in pack rendezvous sites to avoid Wolf-human interactions with study animals. Wolves were sedated with a 5:1 mL mixture of ketamine hydrochloride and xylazine and were weighed, sexed, and examined to assess general condition (Wydeven et al. 1995).

Radio collars were placed on adults. Pups received ear tag transmitters developed for a Wolf pup mortality study (Advanced Telemetry Systems, Isanti, Minnesota) programmed to transmit from 0700 – 1900. Pups and adults were located from the ground using a receiver with either a 5-element hand held Yagi antenna or a 9-element vehicle mounted antenna once daily from time of capture to 15 January each study season. All Wolves were located from fixed-wing aircraft 1-2 times/week.

Human activity observed near pack homesites was documented. Additionally, we interviewed people and collected reports from people who encountered study pack Wolves to assess the relative level of tolerant behavior of study packs towards humans.

Aerial locations of 10 dispersing Wolves were plotted in Universal Transverse Mercator (UTM) coordinates utilizing ArcView 3.X (ESRI, Inc., Redlands, California). Township (human) and residential (structural) densities for each county in which Wolf locations were plotted were queried (U. S. Census Bureau 2005*). Measurements obtained included township densities and residential densities in the county for (1) natal territories from which Wolves dispersed, (2) locations while Wolves were dispersing, and (3) after dispersers settled and either became territorial or became breeders.

Results

We monitored 17 Wolves from three study packs in 2002 and nine Wolves in five study packs in 2003. Seven Wolves and three packs were new in 2003. In three of the six study packs we were able to detail repeated interactions with humans.

Suk Cerney pack: Three male pups, one female pup, a yearling female, and an adult male Wolf were radioed near their den site between 3-6 July 2002 on Necedah National Wildlife Refuge (NNWR) in Juneau County (44°04.957'N, 90°10.399'W). The den site was located approximately 350 m from an observation bunker and several rearing pens used as part of a Whooping Crane (*Grus americana*) reintroduction program located on the NNWR. Between July and October employees and volunteers of the crane project, NNWR staff, along with visiting news media and guests, visited the cranes at least twice per day. Crane staff and Wolf researchers routinely observed pups before and during

FIGURE 1. Capture site of Wolf 409 in central Wisconsin on 10 August 2002 and death site in eastcentral Indiana. June 2003.

our study period. One pup watched Wolf researchers from the den, located in oak savannah dominated by Hill's oak (*Quercus ellipsoidalis*) for approximately 10 minutes as traps were set on 3 July 2002, approximately 10.5 m away. Adult Wolves were rarely seen. However, radio signals confirmed they were often in the immediate vicinity. The 4 radioed pups stayed in the area despite daily human activity, until their deaths between July 15 and 5 September 2002 (Heilhecker 2003*).

Bear Bluff pack: Six Wolves were captured in and adjacent to cornfields on private land in Jackson County between 20 July and 3 August 2002 (44°15.355'N, 90°20.582'W). Two male pups and two female pups, a yearling female, and a yearling male were radio-tagged. A partially planted, sandy soil cornfield with stunted corn stalks < 0.9 m tall, used as a daily rendezvous site from July to early November in 2002 and 2003, was approximately 175 m from the maintenance building used by employees of the cranberry farm at least twice a week. Distance from the rendezvous site to the maintenance building and cranberry beds were approximately 450 m and 1300 m, respectively. White-tailed Deer (*Odocoileus virginianus*), the Wolves' primary prey in the region, were abundant and cause $35000/year damage to local commercial cranberry beds (K. Rice, Flying Dollar Cranberry Company, personal communication). Deer flies (*Chrysops* sp.) and mosquitoes (Culicidae) were generally less abundant in the corn-

fields compared to the surrounding forested land. In both years, and for years prior to our study, employees of the cranberry company regularly observed Wolves. Once during our study they witnessed a Wolf in their parking lot sniffing vehicle tires. The property manager also reported his dog interacting with Wolves in what looked like play behavior.

Noch Hanai pack: Wolf 429, a yearling female, was radio-collared on 3 June 2002. In summer 2002, she was observed multiple times acting indifferently to vehicles along State Highway 54 on the northern border of her natal pack territory (44°20.15'N, 90°35.51'W). In the autumn she dispersed and created a new pack that occupied a 102-km^2 territory centered along the same state highway. The pack's den site was discovered approximately 230 m from State Highway 54 in a Red Pine (*Pinus resinosa*) plantation with no understory. Vehicles passing on the state highway were visible from the den. The wolves' rendezvous sites, as determined by matted grass, trails, human garbage with teeth marks, and deer legs, were on embankments along the shoulder of this moderately traveled state highway, adjacent side roads, and recently logged forests spanning a distance of 7.7 km by 60 m along the state highway.

In summer 2003, over 60 citizen phone calls and e-mails reported a radio-collared Wolf with pups walking, playing, and lying in the middle of the state highway. Initially four pups and a radio-collared adult were observed. On 19 July 2003, a dead male pup was collected from the shoulder of the highway. The necropsy revealed injuries consistent with a vehicle collision.

None of the Wolves appeared to be afraid of vehicles. On 20 July 2003, a citizen reported watching three pups and a collared female in the middle of the state highway. They moved off to the shoulder of the road to let vehicles pass and then returned to the middle of the road. E. Heilhecker and W. Hall, Jr., observed Wolf 429 looking both directions before stepping onto the highway. Pups were observed sitting on the side of the road chewing on deer legs as vehicles passed. Pups once walked next to Heilhecker and Hall's vehicle parked on the shoulder of the road. In all instances the pups appeared oblivious to the presence of vehicles. It was later learned that the Wolves had been fed by loggers working in this area during the late spring/early summer.

On 13 January 2004, WDNR received a report of an uncollared Wolf on State Highway 54 jumping into the bed of a truck containing deer hides and carcasses after its occupant had stopped to take pictures of the Wolf (M. Windsor and T. Babros, WDNR, personal communication). On 29 March 2004, an uncollared Wolf was observed walking back and forth across State Highway 54 stopping traffic. At one point the Wolf picked up a yellow plastic oil container, crossed the road, and lay down within 3 m of a vehicle. Several vehicles slowed down to watch the Wolf. While no one exited their vehicles, people rolled down their windows and continued to talk within hearing range of the Wolf. The Wolf did not appear to be affected by the commotion. On 27 April 2004, the radio-collared female, Wolf 429, was humanely dispatched along Hwy 54 because she was unable to ambulate on her hind legs. A preliminary necropsy was inconclusive, but her paralysis was not caused by a vehicle collision. This Wolf did have a healed injury to the pelvic girdle that was caused by blunt trauma suggestive of an earlier collision with a vehicle (A. Dassow, University of Wisconsin, Madison, personal communication).

Dispersal: We compared aerial locations for 10 Wolves, as yearlings and adults, dispersing between 1998 and 2004. Seven Wolves (W002, W269, W309, W338, W341, W426, W429) established new territories; five of which (W309, W338, W341, W426, W429) were known to have successfully bred. Three Wolves (W337, W427, W480) continued to disperse until their deaths and never set up known territories. Township densities ($\bar{\chi}$ = 9.02 humans/km^2, SE = 4.015) and residential densities ($\bar{\chi}$ = 5.59 housing units/km^2, SE = 2.12) in natal pack territories were significantly lower ($P < 0.01$) than township densities ($\bar{\chi}$ = 43.98 humans/km^2, SE = 7.37) and residential densities ($\bar{\chi}$ = 23.12 housing units/km^2, SE = 3.49) in dispersal and post-dispersal territories (U. S. Census Bureau 2005*).

A male pup, W409, dispersed to eastern Indiana in less than 156 days. The pup was last monitored on 15 January 2003 and found dead on 20 June 2003. If the pup dispersed in a straight line, it would have passed through relatively densely settled areas of northern Illinois and the greater metropolitan Chicago area to reach eastern Indiana (40°06.4'N, 85°04.3'W) (Figure 1). The human density of Jackson County, its birthplace, was 7.8 people/km^2. The least populated counties along the Wisconsin/Illinois state border had 22.9 people/km^2 (Green County, Wisconsin) and 14.5 people/km^2 (Jo Daviess County, Illinois). The human density in Randolph County, Indiana, where the Wolf was found shot was 22.84 people/km^2 (U. S. Census Bureau 2005*). This was the first documented Wolf in Indiana since their extirpation in 1908 (Mumford and Whitaker 1982), and the southern-most movement of a radio-collared Wisconsin Wolf to date (A. Wydeven, WDNR, personal communication).

Discussion

Wolves' reactions to humans are a reflection of their experiences with people and the relative tolerance of humans to Wolves (McNay 2002; Fritts et al. 2003). By the mid-1900s Wolves were largely restricted to wilderness areas in North America due to intense human persecution (Young 1944; Mech 1995). With legal protection from the Endangered Species Act of 1973, a gradual increase in acceptance of Wolves (Fritts et al. 2003), and an expanding population, Wolves have inevitably come in closer contact with humans (Mech 1995; Thiel et al. 1998; Mech and

Boitani 2003). By the 1990s an increasing number of Wolves began dispersing into and colonizing more settled regions and agricultural areas in the northern United States (Licht and Fritts 1994; Mech 1995; Mech and Boitani 2003). Thiel et al. (1998) and Merrill and Mech (2000) reported tolerance of humans close to den and rendezvous sites in Minnesota and Wisconsin.

As Wolves colonize more fragmented habitat dominated by humans they will come into more frequent contact with humans, as our findings demonstrate. Dispersing Wolves from the numerous packs presently inhabiting the forest-farmland zones in Wisconsin and Minnesota are capable of penetrating great distances into landscapes highly dominated by humans (Licht and Fritts 1994; Merrill and Mech 2000; Fritts et al. 2003; Mech and Boitani 2003).

The male Wolf pup, 409, provides an example of this progression of tolerance to humans, a behavior that can be expected to be exhibited by Wolves in succeeding generations. Although movements of ≥ 670 km from their homesites have been well documented in Wolves (Van Camp and Gluckie 1979; Ballard et al. 1983; Fritts 1983; Ream et al. 1991; Licht and Fritts 1994; Merrill and Mech 2000; Mech and Boitani 2003), this is the first documentation of a wild North American Wolf moving through areas of such high human densities. While Wolf 409 was not known to have any contact with nor was known to have been conditioned to humans as a pup, it was subjected to increasing levels of human activity as it dispersed south and east of Lake Michigan. Interestingly, Wolf 429, the founder of what became the human-habituated Noch Hanai pack, came from the very same pack in which Wolf pup 409 was born.

We observed two forms of habituation of Wolves in our study: (1) pups that became accustomed to the presence of humans through repeated, benign association, and (2) association of humans with a food reward. In the two cases where litters were raised in close proximity to human activity and were frequently seen, the pups fled at the close presence or approach of a human(s). These Wolves created no known threats to public safety or caused any damage to personal property. Wolves displaying avoidance or fear behavior during direct encounters with humans are considered to be showing "normal" behavior (Smith and Stahler 2003*).

In the remaining case in our study, pups received food awards from humans. Wolves are not known to attack people during their first human encounter but require repeated exposure to humans before attacking (McNay 2002; Smith and Stahler 2003*). A prerequisite for aggressive Wolf behavior towards humans is habituation, with food being the most influential factor (McNay 2002; Smith and Stahler 2003*). Our human-habituated Wolves' whose bold behavior rapidly evolved into a public nuisance issue.

We expect more Wolf-human encounters and human-habituated Wolves due to the recovering Wolf population in the Great Lakes area. Wisconsin's Wolf population has increased from 83 Wolves in 1995 to 425 Wolves in 2005 (Wydeven and Wiedenhoeft 2005*). The growing Wolf population and increased number of Wolf sightings have raised safety concerns from the general public. A continuous educational program that focuses on how human actions affect Wolf behavior may minimize the establishing of human-habituated Wolves. Periodic news releases and public education programs at the federal and state forests, posters at road side kiosks emphasizing the reasons why feeding of Wolves is improper, writing stipulation in public contracts on public land prohibiting feeding of Wolves especially in areas where Wolf habituation is occurring, or fining individuals who feed Wolves may be useful approaches. When habituation occurs, attempts should be made to deter Wolves displaying bold behavior with aversion techniques such as rubber bullets and cracker shells before Wolf aggression develops. If aversion conditioning is unsuccessful, for public safety reasons, aggressively bold Wolves should be humanely euthanized.

Influence of Gender and Den Type on Home Range Shape for Striped Skunks, *Mephitis mephitis*, in Saskatchewan

Serge Larivière[1,3], David Howerter[2], and François Messier[3]

Larivière, Serge, David Howerter, and François Messier. 2007. Influence of gender and den type on home range shape for Striped Skunks, *Mephitis mephitis*, in Saskatchewan. Canadian Field-Naturalist 121(3): 261-264.

We investigated gender differences in shape of home ranges for Striped Skunks, *Mephitis mephitis*, in southcentral Saskatchewan, Canada, during 1993-1994. Data collected on free-ranging Striped Skunks indicated that shape of female home ranges was unaffected by den type (building versus burrow) and was similar to shape of male home ranges. Moreover, type of maternity den did not influence the position of the den within the home range (inside or outside of core area). We conclude that the distribution of Striped Skunks in summer, and the distribution of their foraging activity, are not affected by the availability of anthropogenic den structures.

Key Words: Striped Skunk, *Mephitis mephitis*, home range, denning site, spatial distribution, Canadian prairies.

Fragmentation of habitats affects not only how animals are distributed in the landscape, but also their use of space. In fragmented landscapes, suitable habitats for foraging may not occur in proximity to other critical habitats for denning, parturition, or rearing of young. Therefore, mammalian females that live in fragmented landscapes face two problems: establishing a home range that includes suitable foraging habitat and finding a site for parturition and rearing of young.

For males that do not provide parental care, obtaining food is a primary drive affecting behavior during summer. In contrast, females give birth and raise a litter during the same period, and habitat preferences for raising young may not coincide with good foraging habitats. In fragmented landscapes, the compromise between optimal foraging and optimal rearing habitats may affect the establishment of home ranges, and consequently their shape. Thus, the location of maternity dens may have several implications for the distribution of foraging activity of females.

First, den location may affect the shape of the home range or the position of the den site within the home range. For example, species that rely on a burrow and central place for refuge and storage of food may benefit from a centrally located den and circular home range (Bowers 1995). However, in fragmented landscapes, females may have to prioritize either establishment of home range (find a good foraging area first, then find a suitable place to rear young within the home range), or the establishment of maternity den (find a good den first, then find a good place to forage).

We investigated the influence of gender and den types on home range shape of Striped Skunks (*Mephitis mephitis*) in the parklands of Saskatchewan, Canada. Striped Skunks are distributed across most of Canada and the United States (Rosatte and Larivière 2003). Females give birth in mid-May, and because males provide no parental care, the progeny are dependent on the mother until mid-July, when the young disperse (Larivière and Messier 1997). In Saskatchewan, female Striped Skunks use two main types of shelter for maternity dens, either anthropogenic structures (e.g., buildings, ca. 60% of maternity dens) or underground burrows (ca. 40% of maternity dens) (Larivière and Messier 1998c). The distribution and availability of both den types differ, and thus, we hypothesized that den type could influence home range shape. For example, buildings may provide good denning structure, but their position may not be in proximity to good foraging areas, a scenario that would yield an elongated home range. In contrast, a burrow may be dug presumably closer to good foraging areas, and thus home range of females using burrows could be more circular in shape. Thus, Striped Skunks provide a good model species to test predictions of den site positioning and home range shape by animals occupying fragmented landscapes.

Study Area and Methods

We conducted this study in the Prairie Pothole Region of southcentral Saskatchewan (52°45'N, 107°08'W). Small grain (i.e., wheat, barley, oats) and oil crops (mostly canola but also flax) occupy 60% of the landscape. Numerous wetlands and stands of Trembling Aspen (*Populus tremuloides*) occur throughout the area. Topography is gently rolling, and an extensive network of roads divides the land. Areas managed for nesting waterfowl are common throughout the area, and consist mostly of dense nesting cover, a mixture of native and tame grasses seeded specifically to attract upland nesting waterfowl. General characteristics of the Prairie Pothole Region are detailed elsewhere (Greenwood et al. 1995).

From April to August, 1993-1994, Striped Skunks were captured in opaque-sided livetraps (Larivière and Messier 1999) and anesthetized using halothane and Telazol® (Larivière and Messier 1996a). All individuals were equipped with a 5-sec delay motion-sensitive radio-collar (150-152 Mhz, Telonics Inc., Mesa, Arizona, USA) to monitor activity during tracking (Larivière and Messier 1997). Skunks were released at the site of capture.

Radio-collared animals were located by an observer using hand-held receiving equipment from 18:00 to 06:00, during the period of greatest activity (Larivière and Messier 1997). Individuals were located every 15 min by direct observation, auditive location, or short-range (<50 m) triangulation (Larivière and Messier 1998b). Light amplifying, night-vision goggles (AN-PVS 5, Bill's Electronics Ltd., Mildmay, Ontario) enabled visual observations at night. Tracking effort was systematically distributed among all skunks, and no animals were tracked during two consecutive nights. Striped Skunks exhibit aposematic behavior, and defensive postures are obvious (Larivière and Messier 1996b). Locations immediately following an observer-induced defensive posture were discarded from analyses due to possible observer disturbance (Larivière and Messier 1998b).

Universal Tranverse Mercator coordinates were obtained from the exact location of the skunk following its departure from the area using a portable Global Positioning System (Ensign GPS, Trimble Navigation, Cansel Survey Equipment, Burnaby, British Columbia). To increase the precision of the coordinates, we only considered locations for which ≥3 satellites were available (D'Eon 1995).

Our radio-tracking schedule was intensive (i.e., locations every 15 min), and designed to maximize direct behavioral information instead of statistical independence within an animal's home range. Using Shoener's ratio, we estimated that statistical independence between locations occurred at intervals of 270 min. However, Striped Skunks are highly mobile, and are capable of moving >1 km in 15 min, even in dense vegetation (Larivière and Messier 1998b). Thus, we assumed that short movements reflected behavioral decisions by the skunk, not physical constraints.

We defined maternity dens as any sites for which at least two of the following criteria were satisfied: repeated use for >3 consecutive days during the parturition/rearing period (15 May - 30 June), collection of grass for preparation of nest chamber, or presence of young during the rearing period (Larivière and Messier 1998a). Because some females may relocate their progeny during the rearing period, and because we could not assess why females changed maternity dens (e.g., to reduce parasite loads, disturbance, relocation to a better foraging area, etc.), we only used data on females with a single maternity den for spatial analysis of den locations within home ranges.

Our entire study area was digitized into a Geographic Information System (SPANS GIS, PCI Geomatics, Richmond Hill, Ontario, Canada). Locations of the maternity dens were plotted for all female skunks, as well as all telemetry locations to determine home range size (Larivière and Messier 1998c) and shape. Home range shape was quantified using a shape index (McGarigal and Marks 1994) that was calculated by the following formula:

$$\text{shape index} = \text{perimeter} / (2 * \sqrt{(\text{pi} * \text{area})}).$$

Thus, a smaller shape index indicates a more circular range. We compared average shape indices for males and females with a Student t-test for unpaired samples. Spatial analyses of activity centres were performed using software package TRACKER and RANGES IV, and core areas (50% minimum convex polygon; Larivière and Messier 1998c) were considered activity centers (Samuel et al. 1985).

Results

In 1993 and 1994, we radiotracked Striped Skunks during 1858 hours, and obtained home range information for 20 females and 5 males. Of the 20 females, 11 used only 1 maternity den during the entire period.

First, we predicted that because of the fixed position of buildings in the landscapes, females using buildings as maternity dens would have home ranges less circular (larger shape index) than those using burrows. This prediction was not supported by our data: the shape index of females using buildings (mean = 1.53, SE = 0.08, $n = 6$) did not differ (one-tailed $t = 0.45$, df = 9, $P = 0.33$) from the shape index of females using burrows as maternity dens (mean = 1.48, SE = 0.07, $n = 5$).

Second, we hypothesized that if females try to minimize the travel distance to any point within their respective home ranges due to lactation constraints, then home range of females should be more circular (smaller shape index) than home ranges of males. Our prediction that home ranges of females are more circular than those of males was not supported: the average shape index for females (mean = 1.46, SE = 0.03, $n = 20$) did not differ (two-tailed $t = 0.59$, df = 23, $P = 0.56$) from the average shape index of male home ranges (mean = 1.50, SE = 0.06, $n = 5$).

Third, we hypothesized that because buildings are preferred denning sites (Larivière and Messier 1998a), some buildings may be used as maternity dens but not be located within the core area of the home range. We predicted that underground burrows should occur in the core areas more often than dens in buildings. Our data also did not support this prediction: there were no associations between den type and whether or not the den was located inside the core area ($n = 12$ females; Fisher exact test, $P = 0.52$). Overall, three underground burrows were inside versus two outside the core area, whereas six buildings were inside versus one outside the core area. In total, 75% of dens were inside core areas.

In this study, we did not detect any effect of den type (anthropogenic or not) on shape of female home ranges or position of the den. Further, the shape of Striped Skunk home ranges was similar among males and females. These findings suggest that female skunks establish home ranges irrespective of den type and with rules similar to males.

Examination of the natural history of Striped Skunks may help explain the patterns observed. First, Striped Skunks in northern environments undergo long periods of inactivity during winter, and to survive such period requires sufficient body reserves (Gunson and Bjorge 1979; Hwang et al. 2007; see also Rogers 1987). Thus, establishing a home range that includes good foraging areas may be more critical than choice of maternity den, but whether choice of maternity den influences juvenile survival remains unknown. In our study area, many buildings that were deemed suitable for occupation by skunks were not utilized (Larivière et al. 1999). As well, numerous females that used underground burrows to rear young had suitable unoccupied buildings within the boundaries of their home ranges. Thus, although buildings may be convenient denning sites, they may not be necessary or provide reproductive advantages to Striped Skunks. If juvenile mortality in skunks mostly occurs after emergence, then anthropogenic den types such as buildings may be used for other reasons such as thermoregulation, protection from the elements, or simply convenience.

During the parturition/rearing period of Striped Skunks, females make nocturnal foraging trips but return to the maternity den by morning to nurse the young (Larivière and Messier 1997). Foraging movements are highly variable (0-20 km per night; Larivière et al. 1998b) and highly opportunistic, although mostly focused on insects and small mammals (Greenwood et al. 1999) and targeted to specific habitats (Bixler and Gittleman 2000; Larivière and Messier 2000). Moreover, habitat availability around used and unused buildings in our study area was similar, suggesting that distribution of resources may not affect location of maternity dens, and conversely that choice of maternity den does not affect access to resources. Suitable den sites likely were not limiting for Striped Skunks (Larivière et al. 1999). The preference of Striped Skunks for buildings may be most obvious where buildings are abundant, but absence of buildings as maternity dens probably does not affect distribution of skunks in the landscape during summer. Hence, our study reinforces the previous suggestion that food, instead of denning structures, probably affects distribution of Striped Skunks and their foraging activity in the landscape.

Acknowledgments

This study was financed by Ducks Unlimited Canada (Institute for Wetland and Waterfowl Research), the Canadian Wildlife Service, and logistic support from Delta Waterfowl Foundation. SL is grateful to Fonds pour la Formation de Chercheurs et l'Aide à la Recherche (FCAR), Québec, for postgraduate and postdoctoral support, as well as to the National Science and Engineering Research Council for an operating research grant. Technical assistance was provided by B. Dinter, E. Howard, G. Poon, L. R. Walton, B. Fry, and D. Anderson. W. A. Gorsuch reviewed an earlier draft of this manuscript. Methods used in this study were approved by the University of Saskatchewan Animal Care Committee (Approval #920091).

Fudge, David, Bill Freedman, Michael Crowell, Tony Nette, and Vince Power. 2007. Road-kill of mammals in Nova Scotia. Canadian Field-Naturalist 121(3): 265-273.

We examined road mortality of wild mammals in Nova Scotia using data from (a) five years of province-wide data on wildlife collisions involving larger mammals, and (b) 20 months of observations of smaller mammals along a 160-km route near Halifax. An average of 2079 White-tailed Deer was reported killed annually on highways during 1999 through 2003, along with 14 Moose and 33 Black Bear. Female White-tailed Deer were more likely to be road-killed than males (by a factor of 1.8), yearlings more so than older animals, and there were peaks of mortality in the late spring and late autumn. The road-kill of smaller mammals was highest in the summer and least in the winter, and the most frequent mortalities were of Raccoon (28% of observations), Porcupine (27%), Skunk (17%), Snowshoe Hare (6%), Coyote (4%), and Groundhog (3%). The standardized kill-rate (number/100 km) was highest on a 100-series highway compared to trunk highways or urban streets, but the rate standardized to vehicle density was highest on trunk highways.

Key Words: White-tailed Deer, *Odocoileus virginianus*, Moose, *Alces alces*, Black Bear, *Ursus americanus*, Raccoon, *Procyon lotor*, Porcupine, *Erethizon dorsatum*, Skunk, *Mephitus mephitis*, Snowshoe Hare, *Lepus americanus*, Coyote, *Canis latrans*, Groundhog, *Marmota monax*, road-kill, mortality, wild mammals, Nova Scotia.

Roads are a defining feature of modern transportation systems. Networks of public roads connect population centers, allowing the movement of people and goods in increasingly larger numbers of fast-moving vehicles. Because much highway infrastructure traverses wildlife habitat, an unfortunate consequence is accidental collisions that threaten the lives of both people and animals, while also causing damage to property (Romin and Bissonette 1996). In Nova Scotia, for example, 503 collisions between vehicles and large wild mammals were reported in 2003, with 68 of the incidents resulting in personal injury requiring emergency services (NSDTPW 2006*). Data relating to the economic costs of such accidents have been quantified in Maine, where they result in US$32 million/year in property damage and medical costs (MEDOT 2001*). Overall in the United States, vehicle accidents involving only White-tailed Deer (*Odocoileus virginianus*) annually result in about 200 human fatalities, 30 thousand injuries, and more than US$1 billion in property damage (Conover 1997). In Europe, collisions with ungulates result in 300 human fatalities and US$1 billion in property damage annually (Bruinderink and Hazebroek 1996). Clearly, a large socio-economic cost is associated with collisions with large animals on roads.

Roads also have important ecological impacts, including the following: (a) damage to populations of some species through mortality; (b) acting as barriers to movement or disrupting behaviour in other ways; (c) destroying and fragmenting natural habitat; (d) causing pollution by de-icing salt, metals, and pesticides; and (e) enhancing access for hunters (Bennet 1991; Evink 1999). The direct mortality of larger animals due to vehicle collisions is relatively apparent and well-quantified (Clarke et al. 1998; Cain et al. 2003; Clevenger et al. 2003; Saeki and MacDonald 2004). Road-kill may affect the conservation status of species – about 65% of the mortality of the endangered Florida Panther (*Puma concolor coryi*) is caused by vehicular collisions (Harris and Gallagher 1989). Other at-risk populations threatened by road-kill mortality include Ocelot (*Leopardus pardalis*) in the U.S. southwest (Tewes and Blanton 1998), the European Badger (*Meles meles*) in Great Britain (Clarke et al. 1998), and the endangered mainland Moose of Nova Scotia (*Alces alces americana*) (NSDNR 2008*).

Many jurisdictions have implemented mitigations to reduce the frequency of collisions between vehicles and wildlife. Often, this is limited to warning signs installed along highway sections known to have high collision rates (AMEC 2004*). In some other places, highways may have perimeter fencing or even wildlife under- and over-passes to keep animals off the roads, particularly in national parks and wilderness areas (Clevenger 1997; AMEC 2004*; NBDOT 2008*). Such mitigations help prevent animals from entering the right-of-way and are successful in reducing mortality, particularly of mammals (Foster and Humphrey 1995). Interestingly, the effectiveness of animal-crossing signs in reducing collision rates has not yet been quantified (MEDOT 2001*).

Despite the fact that collisions with vehicles are an important source of mortality of wildlife, there has been little research into the phenomenon. Putman (1997) argued that such work is necessary, because understanding the biological and ecological influences

on road-kill rates is integral to the design and implementation of effective mitigations to deal with this problem. Within this context, the great majority of research into road-kill has dealt with larger mammals. This focus is due to several socio-economic factors, including the danger to people associated with collisions with large mammals, their economic importance in hunting, and their high public profile (Cain et al. 2003; Clevenger et al. 2003). A few studies have also examined factors influencing road-kills of smaller mammals (Garland and Bradley 1984; Clevenger et al. 2003; Saeki and Macdonald 2004).

In the present study the road-kill mortality of larger- and medium-sized mammals is examined for a variety of roads in Nova Scotia. Two data sets were used: (a) province-wide incident data for larger mammals over a five-year period, and (b) data for medium-sized mammals over a 20-month period along a 160-km work-day commute. We examine biological and environmental factors possibly influencing the road-kill rates, including gender, age, and proximity to distinctive habitats.

Methods

This study was done in Nova Scotia, an eastern province with a population of about 934 thousand people and 23 thousand km of public roads (NSDTPW 2008*). Data for larger mammals were obtained from incident reports of the Nova Scotia Department of Natural Resources (NSDNR), which records road-kill of White-tailed Deer, Moose (*Alces alces*), and Black Bear (*Ursus americanus*), including the location, date, species, sex, and age of the dead animals. Although the reporting of kills is not mandatory, NSDNR estimates that 60-90% of bear and deer collisions and all involving Moose are reported to them (see Conover et al. 1997). The original NSDNR data were taken from a FoxPro database and converted to Excel spreadsheets. The original location coordinates were converted to UTM using ArcView software to allow for analysis by a geographical information system (GIS).

The number of road-kills for each species was summed monthly and annually from 1999 through 2003. The data for White-tailed Deer and Moose were also analyzed by gender and by yearling and multi-year animals. A GIS analysis was used to plot the distribution of road-kills on digital maps, and spatial relationships with road type and traffic volume were examined. In cases where the carcass was not found immediately beside a road, because the wounded animal had moved before it died, the nearest road was inferred as the place of impact. The traffic volume of highway segments was identified for reaches between successive exits and interchanges, using archived data from NSDTPW (2008*). The 100-series highways of Nova Scotia have relatively high traffic volumes and are often four lanes with controlled access, while the trunk highways are relatively low-volume, two-laned, and have free access. The annual road-kill data were standardized on a per-km and per-10^4 vehicles basis, and were compared across highway types and on the basis of adjacent habitat (categories were: mature softwood forest (>60% conifer trees), mature hardwood (>60% angiosperm trees), mature mixedwood, immature forest, agricultural, and urban land-use; a separate analysis involved surface water within 100 m.

The relationship of road-kill density was also compared with indicators of local species abundance for White-tailed Deer and Moose. For deer, density was indicated by county-level Pellet Group Inventory (PGI) data (obtained by NSDNR in the spring, after snowmelt but before green-up, along 460 random 1 km × 2 m transects throughout the province). For Moose, the abundance polygons of Snaith (2001) were used.

Data for smaller mammals were collected over a 20-month period during 1993 through 1994 along a 160-km weekday commuting route (by M. Crowell) from the rural village of Urbania to the urban Burnside Industrial Park in Dartmouth. The route included 106 km of 100-series highway (part of Highway 102), 38 km of trunk highway (Highway 215), and 16 km of urban road. Animals observed dead beside the road were identified to species, as juvenile or adult, and the location was mapped. The annual road-kill data were standardized per km of road, per km^2 of road-bed, and per 10^4 vehicles of traffic density (using archived data from NSDTPW (2008*)). The total-kill data and that for Raccoon (*Procyon lotor*), Porcupine (*Erethizon dorsatum*), and Striped Skunk (*Mephitis mephitis*) were analyzed with respect to adjacent habitat along the surveyed reaches of 100-series highway, including: (a) roadbed being lower than, raised, or level with the adjacent terrain; (b) adjacent habitat being mature softwood forest, mature hardwood, mature mixedwood, immature forest, agricultural, or urban land-use; and (c) surface water within 100 m. A coefficient of similarity was used to make pair-wise comparisons of the relative dominance of species among road-types: $S_s = 2C/(A+B)$, where C is the number of species killed on both road-types, while A and B are the numbers on particular road-types.

Observations and Discussion

White-tailed Deer

A total of 10 397 White-tailed Deer were reported killed in vehicle collisions from 1999 through 2003, or an annual average of 2 079. This mortality is equivalent to about 6% of the estimated deer population, and is a 28% increment on top of the reported hunt (on average, hunters take 20% of the Nova Scotia herd during the fall hunt; NSDNR 2007*). The road-kill rate was similar during 1999 through 2001 (average ± SD: 2 137 ± 102), but greater than during 2002 and 2003 (1 449 ± 44; $P = 0.003$ for difference between the groups of years). The smaller road-kill of 2002-2003 is likely related to a reduced deer herd during that period (NSDNR 2007*).

There was a bimodal pattern of peak mortality of multi-year individuals (of both sexes) during June-

July and October-November (Figure 1a). Other authors have reported a fall peak of deer road-kill, and have attributed this to breeding activities (Puglisi et al. 1974; Case 1978). During the rut, bucks move about in search of receptive females, and does are also relatively vagile during that period (Banfield 1974). The fall hunting season may also increase road-kill rates (Puglisi et al. 1974; Allen and McCullough 1976), although Kilgo et al. (1998) found that deer in Florida generally avoid roads and other open areas when under hunting pressure. The increase of deer road-kill in June-July could be related to such factors as increased rural traffic associated with tourists and cottagers, the availability of high-quality forage and residual de-icing salt along verges, harassment by biting flies and partial refuge from them in open areas, and increased mobility of does with fawns during this time. Puglisi et al. (1974) commented on the attractiveness of early-greening road verges to deer in the springtime. We observed a particularly large peak of road-kill in the spring of 2001 following an extremely harsh winter, during which about half of the provincial herd starved to death because of deep snow cover (NSDNR 2007*).

Adult females were 1.8-times more likely to be killed in vehicle collisions than adult males. This is likely due to the Nova Scotian deer herd being disproportionately female because of the selective removal of males by hunters (Feldhamer et al. 1986; Bruinderink and Hazebroek 1996). Yearling mortality was 11% of the total road-kill mortality, and the kill rate was similar to that of adults (when standardized by estimated population size), although there was little seasonality of the yearling mortality.

The road-kill rate was higher on two-lane secondary highways (0.38 kills/km.yr) than on four-lane 100-series highways (0.13/km.yr). Bashore et al. (1985) made a similar observation in Pennsylvania, where there were more deer road-kills along two-lane roads than along a larger interstate highway. Putman (1997) found that deer would routinely cross secondary roads within their territory, but would avoid larger interstate highways, likely because of their greater width and faster and more plentiful traffic.

The road-kill rate per 10^4 vehicles was higher on secondary ($0.092/10^4$ vehicles) than on 100-series highways ($0.012/10^4$). Overall, however, we did not find a clear relationship between road-kill rates and traffic volume at most of the tested spatial scales, suggesting that more cars do not directly relate to more accidents. Carbaugh et al. (1975) also did not find a linear relationship between traffic density and deer kills, and Armstrong (2005*) reported a slight inverse relationship. Although we did not examine the phenomenon, it is likely that high traffic rates during crepuscular hours would be particularly lethal to deer trying to cross roads (Allen and McCullough 1976).

We observed seven clusters of deer road-kills, each located near a human population centre with a high-density road network. A linear regression using average county data found a positive correlation between the estimated density of deer and that of road-kill ($R^2 = 0.71$; $P < 0.01$).

In some areas, road-kill may exert a controlling influence on local deer populations and slow their recovery from high winter mortality. There are economic implications of such effects because White-tailed Deer are the most valuable wildlife resource in North America in terms of hunting (Conover 1997; DuWors et al. 1999*). Romin and Bissonette (1996) estimated that the inclusive value of deer in North America is about $2 200 per animal (Canadian dollars adjusted for inflation to 2005).

Moose

Seventy Moose were reported killed in vehicle collisions from 1999 through 2003 (average = 14/yr). About two-thirds of the mortality involved the relatively abundant population on the highlands of Cape Breton, which is derived from 18 released individuals (*Alces alces andersoni*) imported from Alberta in the late 1940s (Pulsifier and Nette 1997). The annual road-kill mortality is equivalent to about 0.23% of the Cape Breton population, and 3.7% of the reported harvest by hunters (in 2003; this does not include the Mi'kmaq harvest, which is estimated to be similar to or exceeding the licenced hunter harvest). However, the native mainland population of Moose (*Alces alces americana*) is much less abundant, likely fewer than a thousand individuals, and since 2003 it has been listed as endangered under the *Nova Scotia Endangered Species Act*. The annual road-kill mortality of mainland Moose is equivalent to about 0.5% of the population (there is no legal hunting of this population).

Moose road-kills occurred in all months except April, with a peak of male mortality in October, and of females during June-July (Figure 1b). The autumn peak of male mortality occurs during the rut, when they are competing and moving about in search of receptive females (Banfield 1974). Males also become more aggressive during the rut and may be less averse to roads and traffic (Joyce and Mahoney 2001). The female peak of road-kill in early summer is related to the high volume of tourism-related traffic that occurs then on Cape Breton highways, particularly on the Cabot Trail.

Similar numbers of males and females were killed on the mainland (10 vs. 12), but 1.6-times more females were killed on Cape Breton roads. The latter observation is related to the female-skewed sex distribution of Moose on Cape Breton (the gender ratio of kills by hunters is about three males per two females). Yearling mortality was 11% of the total, but their kill rate was similar to that of adults (when standardized by their estimated population size). There was no obvious seasonality of the yearling mortality.

Of the road-kills on Cape Breton, 85% occurred along eastern sections of the Cabot Trail, where traffic volumes are relatively high. The highest kill rate (0.4/10 km. yr) occurred along a stretch from French

River Bridge to Wreck Cove along the Cabot Trail, within Cape Breton Highlands National Park. On mainland Nova Scotia, the highest road-kill rate was on Highway 104 on the upland Cobequid Pass Toll highway, where 38% of the mainland kills occurred (0.2/10 km.yr). These high-kill areas coincide with regions of Nova Scotia that have the highest density of Moose (Snaith 2001).

Black Bear

One hundred and sixty-four Black Bears were reported killed in vehicle collisions from 1999 through 2003 (average = 33/yr). The annual mortality is equivalent to about 0.5% of the estimated population of Black Bears in Nova Scotia, and 7.2% of the reported harvest by hunters (in 2003). The lowest kill-rate was in 1999 (10 individuals) and the highest in 2003 (57). An unusually large number of 27 bears were road-killed in June 2003, compared to the 1999-2002 June average of 5. This may have been due to an increasing bear population, or the springtime of 2003 being unusually cool and wet, so that animals emerging from hibernation had trouble finding adequate natural food and were attracted to areas near human settlement.

There was a bimodal pattern of road-kill mortality, with peaks in May-June and in October-November (Figure 1c). The first peak is likely due to activity associated with the breeding season, when males wander in search of females (Klenney 1987). The early summer is also when sub-adult animals, at about 15 months of age, leave their mothers to find their own territory (Matson 1967). The fall peak of mortality is likely related to activity associated with pre-hibernation feeding and movement to denning sites (Matson 1967; Davis and Browne 1996). No road-kills were recorded from mid-November to early April, when bears are in hibernation. It was not possible to factor the influence of age or sex on bear road-kill, as these data were not consistently recorded.

Bear road-kills occurred throughout the province, except in southeastern Cape Breton, where the species does not have an established population (Macmichael 2007). The 100-series highways had a higher linear mortality rate (1.58 kills/100 km.yr) than secondary highways (0.032/100 km.yr). According to traffic density, however, the 100-series and secondary highways had similar mortality rates (both 0.02 kills/10^6 vehicles.year). Relative to their total estimated population size in Nova Scotia, Black Bear road-kill rates are lower than those of White-tailed Deer. This may be due to bears being relatively wary of humans and roads, except for habituated animals (Herrero 1985). In addition, deer tend to be relatively abundant in areas of Nova Scotia with high populations of people, especially in agricultural and coastal regions.

Other Mammals

Three hundred and ninety-two smaller mammals of sixteen species were recorded as road-kill on a 160-km study route during a 20-month survey (Figure 1d). The most frequent mortalities were of Raccoon (28% of kills), Porcupine (27%), and Striped Skunk (18%). These are relatively abundant in the study area, often occurring near roads and other habitat edges, and are at inherent risk because they are relatively deliberate in their movements and have a body too large to pass beneath most moving vehicles without impact (Garland and Bradley 1984; Rolley and Lehmen 1992; Clevenger et al. 2003). All species recorded as road-kill are indigenous to the study area, except for Coyote, *Canis latrans*, domestic cat, *Felis domesticus*, and domestic dog, *Canis familarus* (Banfield 1974; Davis and Browne 1996). Additionally, a Red-necked Wallaby (*Macropus rufogriseus*) that had been a 6-month escapee from a wildlife park was found by one of us as road-kill in the Annapolis Valley of Nova Scotia.

Discoveries of small-mammal road-kills (rodents and shrews) were uncommon, but this is likely due to the difficulty of detecting these animals when scanning from a moving vehicle, plus the likelihood that they are quickly scavenged. In addition, small mammals are reluctant to cross multi-lane highways (Clevenger et al. 2003). An innate reluctance to cross open spaces may also explain why Snowshoe Hare, *Lepus americanus* (the most abundant medium-sized mammal in the study area), was killed less frequently than Raccoon, Porcupine, or Striped Skunk, and why their kill rate was higher on the two-lane Highway 215 than on the four-lane Highway 102. Clevenger et al. (2003) also found that Snowshoe Hare was more likely to be killed on narrow roads than on wider ones in Banff National Park, Alberta.

The road-kill rate, when standardized by distance surveyed, was highest on the four-lane Highway 102 (6.0 kills/km) than on the two-lane Highway 215 (4.0/km) or city streets (1.3/km). However, when standardized to traffic density, Highway 215 had a greater rate of mortality (6.3 kills/10^4 vehicles) than Highway 102 (1.9/10^4 vehicles). The kill rate per 10^4 vehicles approached zero on urban streets because of the large traffic volumes, lower vehicle speeds, and likely a relatively small abundance of wild mammals. The lower rate on Highway 102 is likely due to its much greater width and larger volume of faster-moving vehicles, which likely discouraged animals from crossing. Clevenger et al. (2003) also found that relatively wide and high-traffic roads discouraged small- and medium-sized mammals from crossing in Alberta, as did Clarke et al. (1998) for badgers in England.

Similar numbers of species were observed killed on the four-lane Highway 102 (n=12) and on the secondary Highway 215 (n=11), and both exceeded urban streets (only Red Squirrel, *Tamiasciurus hudsonicus*, were observed road-killed in the urban area studied). The most frequent mortalities on the secondary Highway 215 were Raccoon (19% of the total), Striped Skunk (18%), Red Squirrel (16%), Snowshoe Hare

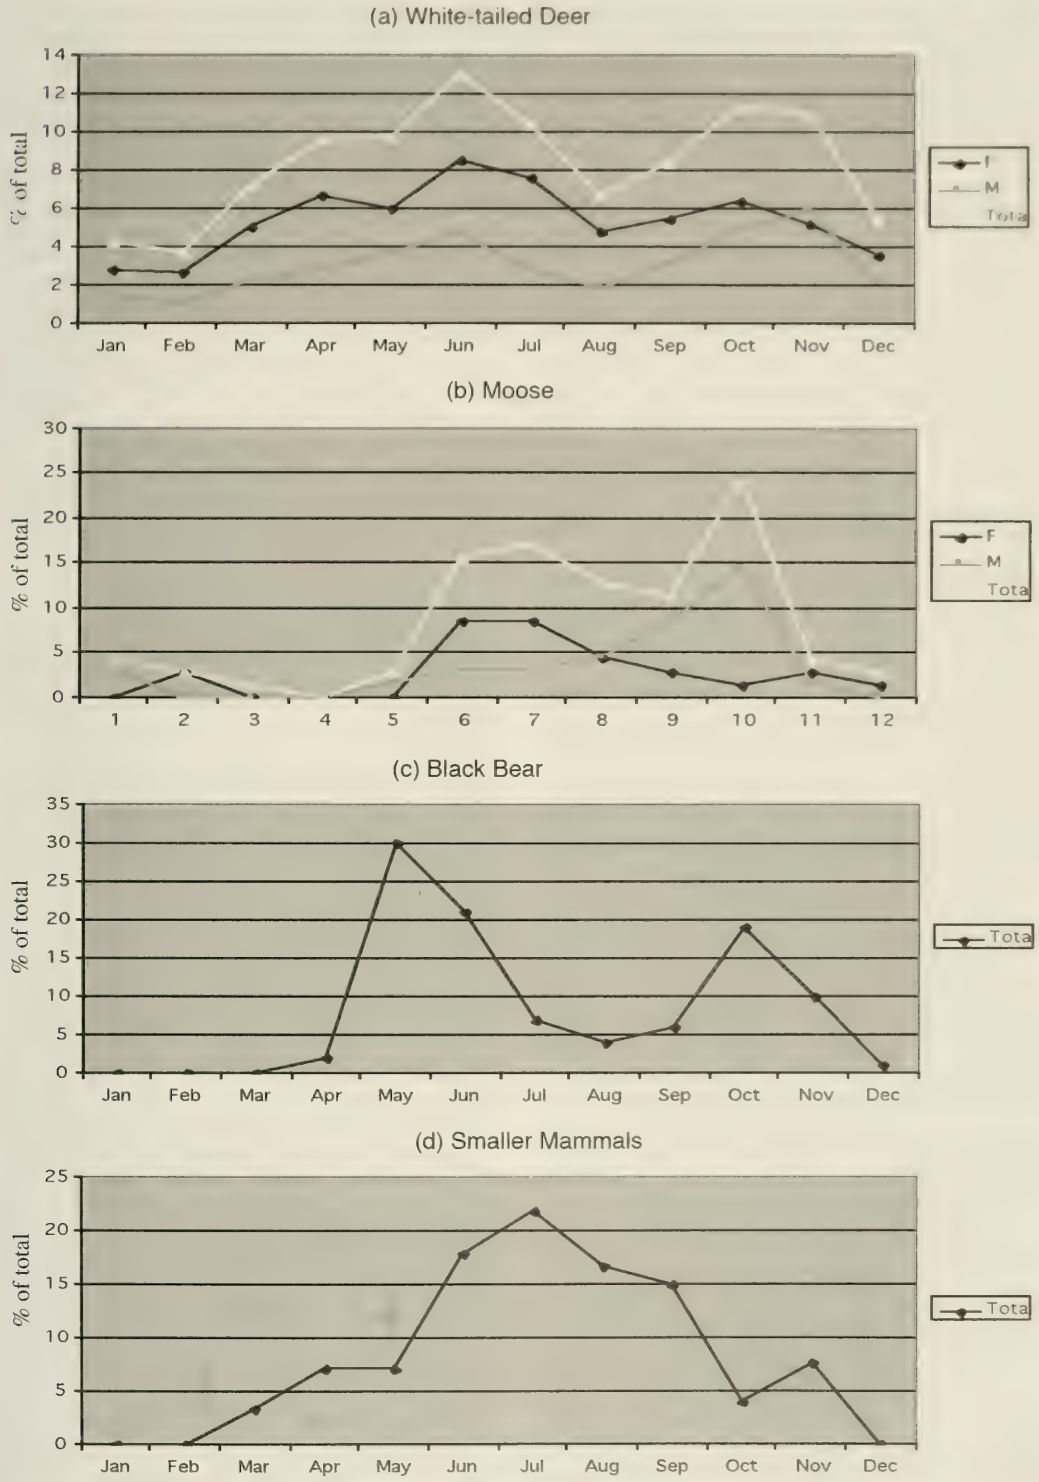

FIGURE 1. Average monthly road-kill mortality of large mammals from 1999 through 2003: (a) White-tailed Deer (n = 10 397); (b) Moose (n = 70); (c) Black Bear (n = 164); (d) smaller mammals (n = 392). Sum of genders may not add to totals, because the sex of some animals was not identified.

(14%), and Porcupine (11%). The most frequent on the four-lane Highway 102 were Porcupine (31%), Raccoon (30%), and Striped Skunk (18%). The species spectrum of mortality of Highways 102 and 215 had a similarity coefficient of 0.78, but their similarity with urban streets was very low – only 0.00 and 0.08, respectively.

The greatest rate of road-kill occurred in the summer months of June (35 mortalities), July (34) and August (22) (Figure 1d). Smaller numbers were recorded in the winter months of November through February, when animals are hibernating or generally less active. The road-kill of Raccoons was highest in May and June, when adult males search widely for females with which to mate (Banfield 1974). In addition, 43% of the Raccoon mortality in May and June was yearlings, which disperse during that time. The mortality of Striped Skunks was highest in September, when juveniles disperse from their natal home range. The mortality of Porcupines was relatively even throughout the spring, summer, and fall.

Partial-deviance tests indicate that roadside topography and habitat were significant predictors of Raccoon road-kill. The likelihood of a Raccoon road-kill was much greater at level roadside topography ($\chi^2 = 11.3$, df = 3, $P < 0.001$) and along segments of highway bisecting mature forest ($\chi^2 = 9.4$, df = 3, $P < 0.05$). Proximity to water did not have a significant effect ($\chi^2 = 0.50$, df = 1, $P > 0.05$). The likelihood of Raccoon road-kill at different roadside topographies was assessed using log-likelihood ratios, and was much greater at level crossings (T-value = 3.1; $P < 0.05$) and along segments bordering mature forest (T-value = 5.9; $P < 0.0025$). For Porcupines, topography ($\chi^2 = 29.4$, df = 4, $P < 0.005$) and proximity to water ($\chi^2 = 5.9$, df = 1, $P < 0.025$) were significant predictors of road-kill. Log-likelihood ratios indicate that road-kill was most frequent at level roadside topography (T-value 4.1; $P < 0.025$) and adjacent to mature softwood forest (T-value 4.0; $P < 0.025$). For Striped Skunks, topography ($\chi^2 = 27.4$, df = 2, $P < 0.005$) was the only significant predictor of road-kill, and the log-likelihood of mortality was much higher at level roadside topography (T-value = 4.1; $P < 0.025$).

Overall, no road-kills of any species were observed at sites where the roadbed was raised (higher than the adjacent terrain), and the likelihood of road-kill was higher on roads bisecting mature forest (mixed, softwood, or hardwood) than adjacent to immature forest, agricultural fields, or urban habitat (T-value 3.8; $P < 0.05$). Proximity to water did not have an overall significant predictive effect.

The results suggest that far fewer road-kills occurred on raised than on level or buried roadbeds. Raised roadbeds could serve as a visual barrier to habitat on the other side, and the banked incline may act as a physical deterrent to crossing. Clevenger et al. (2003) made similar observations for smaller-animal road-kills in Banff National Park, where raised roadbeds had a lower risk of mortality than other topographies.

Another factor potentially affecting road-kill rates is the presence of vegetated center medians on divided highways, such as the grassy ones occurring on Highway 102 in the present study. Bellis and Graves (1971) suggest that these habitats function as temporary refuge areas for animals attempting to cross major highways.

Our study does not allow for an assessment of the impact of road-kill mortality on the local abundances of smaller mammals, as population estimates are not available. If our data were extrapolated to the total length of 100-series (3×10^3 km) and secondary (4×10^3 km) highways in Nova Scotia, the estimated annual mortality within this size range would be 20×10^3 mammals. It can be concluded that the numbers of animals killed on Nova Scotian highways is large, and that this is a significant anthropogenic stressor. Our field data for smaller mammals were collected in 1993-1994, and since then traffic volumes on Nova Scotian roads have increased by about 24% since then (NSDTPW 2008*), so it is likely that road-kill rates have also increased. Moreover, some new roads are being built and the 100-series highways are being expanded, which may also be increasing the rates of road-kill.

Mitigation

Clearly, large numbers of mammals are being killed on Nova Scotian roads, and the further creation and upgrading of highways and increasing traffic may worsen this situation. Moreover, there are important socio-economic consequences of collisions with wildlife. These include injuries to people involved in the collisions, the associated medical costs and time off work, damages to property, and decreases in the populations of animals available to be hunted or trapped. For example, during our study period of 1999 through 2003, White-tailed Deer were involved in 204 vehicle collisions in which people suffered injuries requiring hospitalization, and seven incidents involved a human fatality (NSDTPW 2006*). In fact, White-tailed Deer cause more collision-related property damage and human mortality than any other wild animal in North America (Conover 1997). According to Putman (1996), an average collision with a deer costs about $3 400 in vehicle damage (Canadian dollars, adjusted for inflation to 2005). Using this cost estimate, deer collisions in Nova Scotia during our study period resulted in about $6.8 million in annual property damage, not including costs associated with health care and emergency services.

Fortunately, there are ways to reduce road-kill along highways (Woods 1990*; Clevenger et al. 2001; USDOT 2002*; AMEC 2004*). Some mitigations are intended to change the behavior of animals in ways that make them less likely to enter the right-of-way. For example, fencing is used to prevent animals from

Table 1. Road-kill of smaller mammals over a 20-month study period.

Species	Highway 101		Highway 215		Urban	Total	
	n	%	*n*	%	*n*	*n*	%
Raccoon (*Procyon lotor*)	97	29.9	11	19.3	0	108	27.5
Porcupine (*Erethizon dorsatum*)	101	31.2	6	10.5	0	107	27.3
Striped Skunk (*Mephitis mephitis*)	60	18.5	10	17.5	0	70	17.9
Snowshoe Hare (*Lepus americanus*)	14	4.3	8	14.0	0	22	5.5
Domestic Cat (*Felis domesticus*)	17	5.2	4	7.0	0	21	5.4
Coyote (*Canis latrans*)	13	4.0	0	0.0	0	13	3.3
Groundhog (*Marmota monax*)	10	3.1	2	3.5	0	12	3.1
Red Squirrel (*Tamiasciurus hudsonicus*)	0	0.0	9	15.8	3	9	2.3
Domestic Dog (*Canis familiaris*)	4	1.2	2	3.5	0	6	1.5
Red Fox (*Vulpes vulpes*)	4	1.2	0	0.0	0	4	1.0
Eastern Chipmunk (*Tamias striatus*)	0	0.0	3	5.3	0	3	0.8

Total Species = 16	324		57		3	392	

crossing major roadways in at least eleven U.S. states (MEDOT 2001*), New Brunswick, and in the Canadian Rockies. In Banff National Park, for example, fencing resulted in a 96% reduction in large-mammal road-kill (Clevenger 1997). It is generally recommended that fencing be at least 2.6 m in height, including above winter snow levels (USDOT 2002*). However, fencing also has drawbacks, because it can fragment populations and may trap animals within a right-of-way that they may enter via a break or at a fence-end (Phillips 1999*). Phillips (1999*) estimated that fencing along a major highway in New Brunswick typically costs $40 000 to $80 000 (Canadian) per kilometer. At present, the only areas in Nova Scotia with wildlife fencing along road verges are on the Cabot Trail on Cape Breton Island to prevent devastating collisions with Moose in segments where there are steep drop-offs along the highway, and an area near Magazine Hill in Dartmouth that had experienced a high number of accidents with deer.

Although extremely expensive, structural crossings can be installed to allow for the movement of animals across a right-of-way. This mitigation can help prevent local and even regional populations of certain animals from becoming fragmented, with potentially deleterious consequences, while also avoiding risks to people and property from collisions. Crossing structures include underpasses, overpasses, and modified watercourse structures (a kind of underpass). However, not all animals will use structural crossings. Reed (1981) observed that Mule Deer (*Odocoileus hemionus*) were reluctant to use enclosed underpasses, and they did not acclimatize to them over a study period of 10 years. He suggested that deer were far more willing to use open "bridge" style overpasses than underpasses. A review by USDOT (2002*) also concluded that ungulates were most likely to use overpass structures. The installation of a single overpass crossing structure can cost Canadian $1.4-2.6 million, while underpasses and modified watercourse structures are generally $92 000 to $420 000 (MEDOT 2001*).

Another useful mitigation is to make drivers more aware of potential dangers and to reduce vehicular speeds (AMEC 2004*). These driver-orientated approaches include signage and educational programs. Passive warning signs (sometimes with flashing lights) of White-tailed Deer and Moose are used in many places in Nova Scotia and elsewhere to alert motorists to increased risks of collision with wildlife, generally in places where repeated collisions have occurred (AMEC 2004*). Although there are no data supporting the efficacy of signs, they likely have limited effectiveness because they rely on driver attentiveness, yet people quickly become desensitized to them (USDOT, 2002*). Passive signs are, however, relatively inexpensive to install and maintain.

Driver education related to road-kill may make motorists more aware of the potential for wildlife encounters, and therefore better prepared to avoid them. For example, a program called "Watch out for Wildlife" is delivered in the public-school system and by driver-education messaging in Florida (Evink 1999). The effectiveness of education programs in reducing road-kill is difficult to quantify, although people skilled at spotting animals and predicting their behaviour tend to be involved in fewer collisions (Joyce and Mahoney 2001).

In Nova Scotia, enhanced public awareness of wildlife-collision risks could be promoted by an increased educational program. In addition, fencing verges in stretches of all major roads known to have high kill rates of larger mammals would reduce hazards, partic-

ularly for conservation of the at-risk mainland Moose population along the Cobequid Pass of Highway 104 (which also has high rates of bear and deer road-kills). However, roadside fencing could also detrimentally fragment the habitat of the already-small populations of mainland Moose in these areas.

Of course, mitigations have significant costs, but they provide large benefits by reducing property damage and risks of injury to people and wildlife.

Acknowledgments

This work was supported by a Discovery Grant to BF from the Natural Sciences and Engineering Research Council of Canada. Lester Hanley of the Nova Scotia Department of Transportation provided traffic statistics for roads, Jennifer Milne and James Boxall of Dalhousie University assisted with the GIS analysis, and Cathy Wambolt with statistical analysis.

Third Census of Seabird Populations of the Gaspé Peninsula, Québec, 2002

Richard Cotter and Jean-François Rail

Canadian Wildlife Service, P. O. Box 10100, Ste-Foy, Québec G1V 4H5 Canada

Cotter, Richard, and Jean-François Rail. 2007. Third census of seabird populations of the Gaspé Peninsula, Québec, 2002. Canadian Field-Naturalist 121(3): 274-286.

In the tradition of the quinquennial census of seabirds in the Migratory Bird Sanctuaries along Québec's North Shore, which began in 1925, this paper presents the results of the first three seabird censuses of the Gaspé Peninsula conducted in 1979, 1989, and 2002, with an emphasis on the third census and on changes in seabird populations that occurred between the second and third censuses. In 1979 the population of seabirds was estimated at 134 163 birds, and this increased 72% to 231 186 birds in 1989. The upward trend in population continued in the 1990s but less sharply. The 2002 census recorded 279 276 birds, a 21% increase over the second census. The seabird community of the Gaspé Peninsula comprises 14 species. In each of the three censuses, three species accounted for over 75% of the total seabird population: Northern Gannet, Black-legged Kittiwake, and Common Murre. Between 1989 and 2002, Common Eider, Northern Gannet, Great Cormorant, Ring-billed Gull, Razorbill, and Black Guillemot increased in numbers, whereas Herring Gull, Black-legged Kittiwake, and Common Tern all suffered declines. Populations for Double-crested Cormorant, Great Black-backed Gull, and Common Murre all remained stable. Very small populations (<25 birds) of Leach's Storm-Petrel and Atlantic Puffin have been recorded during the censuses at only one location, Bonaventure Island. In the 2002 census there were no petrels observed, neither of adults nor of active burrows.

À l'instar des inventaires quinquennaux des oiseaux marins dans les refuges d'oiseaux migrateurs de la Côte-Nord, entrepris en 1925, cet article présente les résultats des trois premiers inventaires complets des oiseaux de mer nicheurs en Gaspésie, menés en 1979, 1989 et 2002. Une attention particulière est mise sur le statut des espèces d'après le troisième inventaire, et sur les tendances des populations entre les deux derniers inventaires. En 1979, le nombre d'oiseaux marins nicheur était évalué à 134 163 oiseaux, puis ce total a augmenté de 72% pour atteindre 231 186 oiseaux en 1989. Cette tendance à la hausse a continué dans les années 90, mais moins rapidement. En 2002 l'estimation était de 279 276 oiseaux, soit une hausse de 21 % par rapport au deuxième inventaire. La communauté d'oiseaux de mer de la Gaspésie est formée de 14 espèces nicheuses. Dans chacun des trois inventaires, trois espèces représentaient plus de 75 % de la population totale des oiseaux marins: le Fou de Bassan, la Mouette tridactyle, et le Guillemot marmette. Entre 1989 et 2002, l'Eider à duvet, le Fou de Bassan, le Grand Cormoran, le Goéland à bec cerclé, le Petit Pingouin et le Guillemot à miroir ont vu leurs nombres croître, tandis que le Goéland argenté, la Mouette tridactyle et la Sterne pierregarin subissaient des déclins. Les populations de Cormoran à aigrettes, Goéland marin et Guillemot marmette sont demeurées stables. Les petites populations (<25 oiseaux) d'Océanite cul-blanc et de Macareux moine n'ont été vues durant ces inventaires qu'à l'île Bonaventure. Cependant, aucun nid actif d'océanite ne fut localisé à cet endroit en 2002.

Key Words: Seabirds, populations, larids, alcids, Gaspé Peninsula, Bonaventure Island, Forillon National Park, Québec.

Seabird populations of the Gaspé Peninsula have long been well known due to two very popular summer tourist destinations: Forillon National Park of Canada and the town of Percé. At Percé boat tours are offered around Rocher Percé and Bonaventure Island, which together form a provincial park as well as a federal Migratory Bird Sanctuary. The most striking features of these sites are the high vertical cliffs holding large Black-legged Kittiwake colonies and the spectacular Northern Gannet colony on Bonaventure Island. (Scientific names are in Table 1.) With eight breeding seabird species numbering more than 100 000 pairs in 2002, Bonaventure Island is undoubtedly the most important seabird colony in the area; nevertheless, the smaller mainland cliffs, together with a few islands and sand bars distributed around the peninsula, are also home to numerous colonies of cormorants, gulls, guillemots and Razorbills.

Chapdelaine and Brousseau (1992) published the first account the distribution and abundance of all seabird species breeding along the entire Gaspé Peninsula in eastern Québec. They presented the results of the first systematic censuses of seabirds for the region–in 1979 and 10 years later in 1989–as well as changes in populations and distribution for each species. After an interval of 13 years, in 2002 the Canadian Wildlife Service conducted a third seabird census. The objective of this paper is to present the results of all three censuses, but with an emphasis on describing the changes in seabird populations and distribution that occurred between 1989 and 2002. This paper therefore complements and updates Chapdelaine and Brousseau (1992) who discussed the changes that occurred between 1979 and 1989.

Methods

On the Gaspé Peninsula, seabird species (Table 1) were censused at 59 breeding sites (Table 2, Figure 1) during June and early July in 1979, 1989, and 2002 by the Canadian Wildlife Service-Québec Region. There

TABLE 1. Species names and summary of census methods used for each species in the 1979, 1989, and 2002 seabird censuses of the Gaspé Peninsula.

English name	Scientific name	Methodology
Common Eider	*Somateria mollissima*	systematic counts of all nests, except for Îlot Mahy nord where flushed females were counted
Leach's Storm-Petrel	*Oceanodroma leucorhoa*	systematic counts of active burrows
Northern Gannet	*Morus bassanus*	population analysis from aerial photography
Double-crested Cormorant	*Phalacrocorax auritus*	nests counted from a boat, except for the Upper Plateau of Rocher Percé where nests were counted from a look out point using a spotting scope
Great Cormorant	*Phalacrocorax carbo*	nests counted from a boat
Ring-billed Gull	*Larus delawarensis*	systematic counts of all nests
Herring Gull	*Larus argentatus*	systematic counts of nests; ratio calculated where nested with Great Black-backed Gulls; counts of incubating adults on cliffs made from a boat
Great Black-backed Gull	*Larus marinus*	systematic counts of nests (sometimes from boat); ratio calculated where nested with Herring Gull
Black-legged Kittiwake	*Rissa tridactyla*	Bonaventure Island, Cap d'Espoir, Forillon Peninsula: counts derived from photographs (taken from boat); elsewhere nests were counted from a boat
Common Tern	*Sterna hirundo*	systematic counts of all nests
Common Murre	*Uria aalge*	counts of birds at colonies on cliffs; used a conversion factor of 0.76 pair/bird observed
Razorbill	*Alca torda*	counts of birds at colonies on cliffs
Black Guillemot	*Cepphus grylle*	counts of birds at colonies on cliffs and on the water; used Cairns (1979) conversion factor to estimate the number of breeding pairs
Atlantic Puffin	*Fratercula arctica*	counts of adult birds

were three exceptions with respect to the year of the census, and these were: Black Guillemots at Cloridorme to Marsoui were counted in 1980 instead of in 1979, Common Eiders at Pointe de Sandy Beach were counted in 2003 instead of in 2002, and Northern Gannets at Bonaventure Island were counted in 2004 instead of in 2002. The census techniques employed varied among species and colonies but were consistent for each colony among the three censuses (i.e., 1979, 1989, and 2002). A detailed explanation of the techniques used in 1979 and 1989 can be found in Chapdelaine and Brousseau (1992); with few exceptions the same methods were used in 2002. A brief description of the techniques used in 2002 for each species is presented in Table 1. Certain species, such as Black Guillemots and Herring and Great Black-backed gulls, nest in colonies as well as solitary pairs or in very small groups. As such, for these species the distribution and colony size data may pertain to a section of shoreline rather than a discrete colony. At colonies where a species was believed to have been present but there are no population estimate available, a "+" is indicated in the corresponding table. To examine changes in population sizes between the three censuses, that is from 1979 to 1989 and from 1989 to 2002, the compound annual growth rate (CAGR) was calculated for each species using the formula: CAGR = $(((N(t)-N(0))/N(0)+1)^{1/t})-1$ where $N(t)$ = population size at time t, $N(0)$ = population size at time 0 and t = number of years between two censuses.

Results

During the surveys in 1979, 1989, and 2002, a total of 14 species of seabirds was recorded at 59 breeding sites (colonies and/or shoreline sectors) around the Gaspé Peninsula (Tables 1, 2). Twelve species were observed in all three censuses, with the remaining two absent in one of the census years (Tables 3-8). In 2002, 13 species were observed, with only the Leach's Storm-Petrel not recorded. In terms of total abundance (number of individuals) and breeding sites, the censuses recorded 134 163 birds at 44 sites in 1979, 231 186 birds at 58 sites in 1989, and 279 276 birds at 57 sites in 2002 (Table 8). In each of the three survey years, three species accounted for over 75% of the total seabird population—Northern Gannet, Black-legged Kittiwake, and Common Murre. Individual species accounts are as follows:

Common Eider: In 2001, the total population of breeding eiders (subspecies *dresseri*) in the St. Lawrence Estuary and Gulf was estimated at 42 000 pairs (The Joint Working Group on the Management of the Common Eider 2004). The 2002 seabird census of the Gaspé Peninsula recorded only 235 pairs of this eider, which represents less than 1% of the total population in Québec. Nevertheless, the population is steadily increasing, from 41 pairs in 1979 to 128 pairs in 1989 to 235 pairs in 2002 (Table 8). In 2002 this seabird bred at Îlot Mahy nord, Île Plate, and Pointe de Sandy Beach (Table 6). A few pairs are also believed to nest each year at the foot of the cliff on the Forillon Peninsula.

TABLE 2. Number, name, and centroïd coordinates of sites on the Gaspé Peninsula surveyed for nesting seabirds in 1979, 1989, and 2002. (Colony numbers correspond to locations in Figure 1.)

[1] For shoreline sections, the coordinates of the starting locations are given.

Leach's Storm-Petrel: On the Gaspé Peninsula, this petrel has only ever been known to nest at two locations, Forillon Peninsula and Bonaventure Island. By the 1930s, the Forillon colony no longer existed (Ball 1938), leaving only the Bonaventure Island colony. This colony was probably never large–in the 1979 and 1989 censuses only 10 and 21 pairs were counted, respectively. Unfortunately, no petrels (nor active burrows) were observed in the 2002 census (Table 7). In fact, this species' breeding status in Québec is currently uncertain. Historically, it nested at several locations along the North Shore of the Gulf of St. Lawrence and on the Magdalen Islands. However, the only active colony found in the 1998-1999 census of North Shore Migratory Bird Sanctuaries (Corossol Island with 718 active burrows, Rail and Chapdelaine 2004) was deserted in the 2005 census (Rail and Cotter 2007), and no active burrow has been recorded on the Magdalen Islands in the last 20 years, although observations in 2007 of adults in the Île Brion Ecological Reserve during a survey for this species suggest a small colony still exists there (CWS, unpublished data). In some cases, including Bonaventure Island, the presence of Red Foxes (*Vulpes vulpes*) might be responsible of the abandonment of the colony.

Northern Gannet: On the Gaspé Peninsula, this species nests only on Bonaventure Island. During the last census the Northern Gannet was the most abundant of all seabirds with an estimated 53 635 pairs (Table 8). Since 1979 this gannet colony has grown at a fairly consistent rate; the compound annual growth rate (CAGR) was 2.8% between 1979 and 1989 and 5.5% between 1989 and 2004 (Table 8). This colony was also censused in 1999 and was estimated at 36 936 pairs; the CAGR for 1999 to 2004 was 7.7%. In 1999 and 2004 the colony showed no sign of density-dependant effects, and because breeding success estimates obtained in 1999 and 2004 were high and stable (CWS, unpublished data), we think that the colony should continue to increase in the next few years.

Double-crested Cormorant: After a doubling in population size between 1979 and 1989, the size of this cormorant's population on the Gaspé Peninsula did not change substantially between 1989 and 2002 (CAGR of only 0.4%), reaching 4 889 pairs in 2002 (Table 8). A stabilization in populations between the mid-1980s

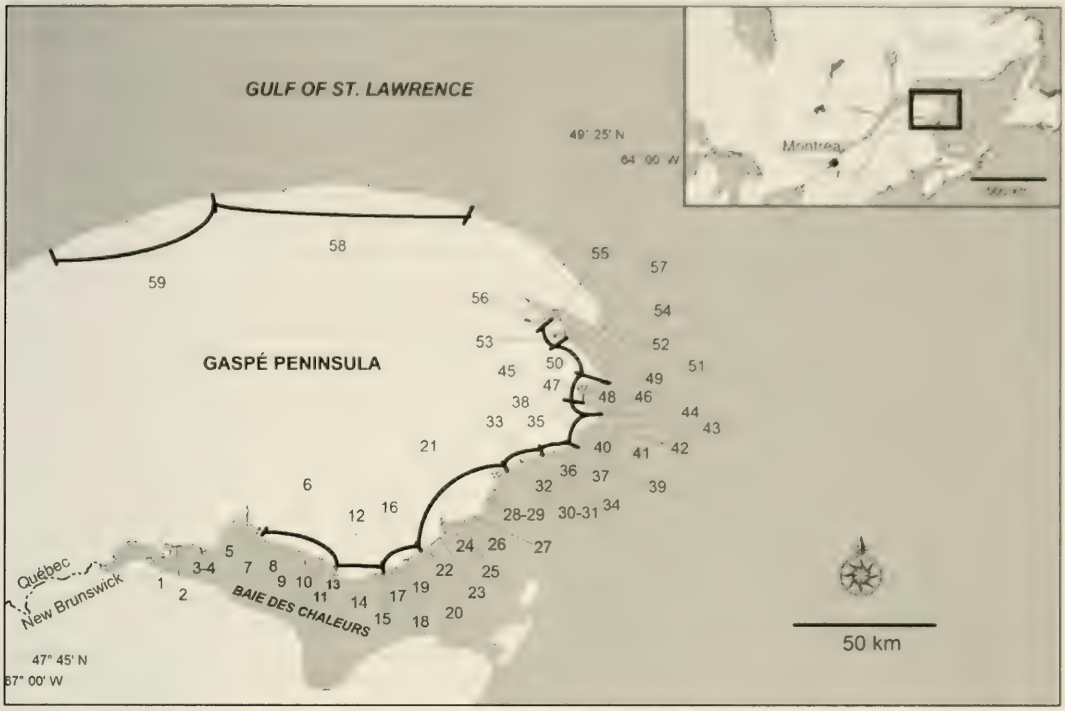

FIGURE 1. Location of colonies and shoreline sectors on the Gaspé Peninsula surveyed for breeding seabirds in 2002. See Table 2 for location listings and coordinates.

and the early 2000s has also been recorded in Nova Scotia (Boyne and Beukens 2004) and New Brunswick (Boyne and Hudson 2002). In Québec, the population on the Magdalen Islands also remained fairly stable between 1990 and 2002 (CWS, unpublished data), as did the overall population in breeding colonies within the Migratory Bird Sanctuaries along the St. Lawrence North Shore between 1993 and 2005 (Rail and Cotter 2007). Interestingly, the increase in the size of the Gaspé population between 1979 and 1989 was accompanied with an additional nine new colonies in 1989, bringing to a total of 29 active colonies that year. In 2002, however, there was a contraction in the number of sites where it nested, as it was recorded at only 25 sites (Tables 4, 6, 7). Of the nine new colonies in 1989, three were not active in 2002. Additionally, six colonies that were active in both 1979 and 1989 harboured no cormorants in 2002. The loss of these nine colonies was offset by five new colonies, including one comprising 393 pairs in the New Richmond-Bonaventure region and, interestingly, a small colony on Bonaventure Island. As Chapdelaine and Brousseau (1992) stated, the majority of Double-crested Cormorant colonies on the Gaspé Peninsula are found on sea-cliffs that in some areas are unstable and subject to erosion. Thus it is not surprising that between censuses with an interval of ≥10 years there are colonies that become inactive and new ones are created.

Great Cormorant: World-wide this species has the largest breeding distribution of all cormorant species, but only a small fraction of its population nests in North America (Hatch et al. 2000). In Québec there are approximately 20 small colonies (total population <1500 pairs) (CWS, unpublished data), with historically only one colony on the Gaspé Peninsula at Rocher Percé. In 1979 this colony had 16 nesting pairs, and in the 1989 census this number had doubled to 35 pairs. This upward trend continued in the 1990s as the total Gaspé population reached 96 pairs in 2002 (Table 7). In that census, the Rocher Percé colony had changed little in size since 1989, but a new and fairly large colony of 50 pairs was found at Cap d'Espoir (Table 7). Small numbers (1-3 pairs) were also observed at four other sites in 2002 (Tables 4, 6), which along with the new colony at Cap d'Espoir may indicate the population is expanding not only in size but also in its distribution. Rail and Chapdelaine (2004) also reported on the recent appearance of small Great Cormorant colonies in North Shore Migratory Bird Sanctuaries, although the most recent survey of these sanctuaries, in 2005, recorded only 48 Great Cormorants, a sharp decrease from the previous survey in 1998-1999 when 342 adults were counted (Rail and Cotter 2007).

Ring-billed Gull: This gull, whose first breeding record in the Maritime Provinces was in 1965 (Lock 1988), is also a newcomer to the Gaspé Peninsula. It

was absent during the 1979 census, and in 1989 only 21 pairs were counted at two sites, Barachois de Chandler and Pointe de Sandy Beach (Table 5). In the 2002 census, however, there was only one colony and it was not at either of those two sites. Instead it was at Saint-Omer, and the colony was surprisingly quite large with 1663 pairs (Table 3). There were more Ring-bills at this site than the traditional species that nest there, that is Herring and Great Black-backed gulls and Common Terns. With numbers of Ring-billed Gulls still rising in the Maritimes (Boyne and Hudson 2002; Boyne et al. 2006) and apparently also on the North Shore (Roberge 2004), it is not surprising to observe the same trend around the Gaspé Peninsula.

Herring Gull: Among all seabirds on the Gaspé Peninsula, the Herring Gull is the only species whose population declined in size between 1979 and 1989 and again between 1989 and 2002 (Table 8). From 1979 to 1989 its CAGR was -1.8%, and this rate of decline doubled to -3.5% between 1989 and 2002. Between 1979 and 2002, the total population declined from 9796 to 5134 pairs. This decline is attributable to colonies decreasing in size as opposed to a reduction in the number of breeding sites (24 in 1979 vs 29 in 2002; Table 8). In 2002, 22 of the 29 colonies had fewer gulls than in 1989. There were, however, four colonies/sectors that increased in size by more than 50% between 1989 and 2002: Saint-Omer, Île Taylor, Marais de Paspébiac, and the New Richmond to Bonaventure sector (Tables 3, 5). These four areas along with Îlot Mahy sud and Pointe de Sandy Beach comprised 64% of the total Herring Gull population on the Gaspé Peninsula in 2002. The decline in colony size is probably not a result of competition, such as for nest or foraging areas, with other larids. Among the 22 sites where the population declined between 1989 and 2002, there were only two–Îlot Mahy sud and Île Plate–that had a sizable increase in the population of another seabird, and at both sites it was of Great Black-backed Gulls (three other sites had smaller increases in their Great Black-backed Gull populations; Tables 3, 5). Along coastal New England, however, the more aggressive Great Black-backed Gulls have displaced Herring Gulls from certain good breeding sites, and Rome and Ellis (2004) found evidence there that Great Black-backed Gulls may suppress foraging by Herring Gulls. Elsewhere in Canada, populations of Herring Gulls have also declined in Newfoundland (Robertson et al. 2004), New Brunswick (Boyne and Hudson 2002), Nova Scotia (Boyne and Beukens 2004), and Prince Edward Island (Boyne and McKnight 2005). Chapdelaine and Rail (1997) showed that there was a positive relationship between Herring Gull populations in the North Shore sanctuaries and cod fishery activities in the Gulf of St. Lawrence, the latter providing substantial amounts of fish offal and discards to breeding gulls. After a thriving period that lasted up to the end of the 1980s, the cod fishery collapsed, a situation which probably triggered the decline of the Herring Gull populations on the North Shore (-70% between 1988 and 1993; Chapdelaine 1995) and around the Gaspé Peninsula as well (-37% between 1989 and 2002). We think that the disappearance of this abundant anthropogenic food source brought Herring Gull populations back to a more "natural" level, which will stabilize in the future, as has been observed in North Shore sanctuaries since the early 1990s (Rail and Cotter 2007).

Great Black-backed Gull: This large gull often nests in mixed colonies with its more abundant relative, the Herring Gull. Unlike that species, however, Great Black-backs increased dramatically in numbers on the Gaspé Peninsula between 1979 and 1989, with a CAGR of 23.7%. After reaching a population of 1 337 pairs in 1989, the population in 2002 was relatively unchanged with 1 322 pairs. The large increase from 1979 to 1989 was due in part to colonies increasing in size but also to a doubling in the number of colonies (Table 8). Comparing 2002 with 1989, there were a few changes in colony locations. In 2002 this gull did not nest at Barachois de Chandler but colonized the Banc de la baie du Grand Pabos in the adjacent bay, less than 1 km away. It also deserted the cliffs from Paspébiac to Shigawake, but became established between New Richmond and Bonaventure. Elsewhere, in each of the neighbouring Maritime Provinces Great Black-backed Gull numbers declined between the late 1980s and early 2000s (Boyne and Beukens 2004; Boyne and Hudson 2002; Boyne and McKnight 2005). In the Migratory Bird Sanctuaries (excluding Gros Mécatina and Saint-Augustin) along the St. Lawrence North Shore, however, the population has been relatively stable, with 1 883 individuals counted in 1988 and 1 835 individuals counted in 2005 (Rail and Chapdelaine 2004; Rail and Cotter 2007).

Black-legged Kittiwake: This small larid was the most abundant seabird species in both 1979 and 1989 (Table 8). The size of the kittiwake population on the Gaspé Peninsula doubled in size in the 1980s, from 21 827 pairs in 1979 to 43 423 pairs in 1989. This species' distribution and abundance between 1974 and 1985 have been described in detail for the entire Gulf of St. Lawrence by Chapdelaine and Brousseau (1989). In the 1990s, the population stopped growing, and in 2002 there were 13% fewer pairs (37 649) than there were in 1989. Recent downward trends (i.e., negative annual growth rates) have been observed in other regions of eastern Canada: Magdalen Islands (Québec), -1.0%/year, 1989-2000; Anticosti Island (Québec), -2.3%/year, 1985-2004; North Shore Migratory Bird Sanctuaries (Québec), -8.0%, 1988 to 1998-1999 but followed by a stabilization with a rate of 0.64%, 1998-1999 to 2005; Gull Island (Newfoundland), -2.2%, 1971-2001; Great Island (Newfoundland), -9.9%, 1994-2003; and Baccalieu Island (Newfoundland), -3.6%, 1984-2003 (CWS, unpublished data; Rail and Cotter 2007; Robertson et al. 2004; G. Robertson, personal communication). In each of the

[1] Bonaventure Island censused in 2004 instead of in 2002.
[2] Annual estimates used in calculating the Total estimate are underlined.

three Gaspé Peninsula censuses, five colonies comprised ≥95% of the total kittiwake population: Cap d'Espoir, Bonaventure Island, Les Trois Soeurs, Rocher Percé, and Forillon Peninsula (Tables 5, 7). Comparing colony sizes in 2002 with 1979, the former three colonies had changed by less than ±35%, whereas the latter two had increased substantially in size, in particular Rocher Percé, which increased from 16 pairs in 1979 to 1 094 pairs in 2002 (Table 7). In each of the three censuses, the Bonaventure Island colony harboured the most kittiwakes, with an estimated 18 550 pairs nesting in 2002. After the 1989 census, at which time there were 23 650 pairs at this colony, Chapdelaine and Brousseau (1992) postulated that the Bonaventure Island colony may have reached its peak due to a lack of available nesting habitat.

Common Tern: Of all species censused in 1979, 1989, and 2002, the Common Tern had the greatest change in CAGR over the 1989 to 2002 period as compared with 1979 to 1989 (Table 8). In that first interval, the population increased at an annual rate of 18.0%, from 459 pairs in 1979 to 2 407 in 1989. From 1989 to 2002, however, the tern population declined at a CAGR of -13.1%. The 2002 population was estimated at only 388 pairs, which is fewer birds than there were in 1979 (Table 8); only one other species, the Leach's Storm-Petrel, had a smaller population in 2002 than in 1979. Terns have never nested at a large number of sites on the Gaspé Peninsula. In 1979 the Common Tern nested only at Banc de Carleton and Pointe de Sandy Beach, and both of these colonies had increased considerably in size by 1989 and were the largest of all tern colonies, with each containing over 800 pairs (Tables 3, 5). In addition to these two colonies, there were four new colonies in 1989, and among these six colonies four had 200 or more nesting pairs. In 2002, however, there were only four colonies, of which three consisted of 20 or fewer pairs. During this census there were no terns at Banc de Carleton and only 20 pairs at Pointe de Sandy Beach. The only bright spot for this species was the colony at Saint-Omer, which was a new colony in 1989. In that year this colony consisted of 133 pairs, which increased to 333 pairs in 2002. Elsewhere in Québec, tern numbers on the Magdalen Islands were quite stable between 1990 and 2000 at around 2 600 pairs (CWS, unpublished data), and in the Mingan Archipelago National Park Reserve, on the North Shore of the Gulf of St. Lawrence, numbers have been increasing in the last 20 years, with more than four thousand pairs in 1999 (Roberge 2004). In neighbouring New Brunswick, the number of Common Terns along the Gulf of St. Lawrence coast has been relatively stable, with a small decline between 1983 (15 500 pairs) and 2000 (12 618 pairs) and then a small increase in 2005 (13 283 pairs) (Boyne et al. 2006). The situation on Prince Edward Island over this same period has been more drastic, as the island's population fell from

[1] Censused in 2004.

approximately 3 000 pairs in 1984 to 738 pairs in 2004 (Boyne and McKnight 2005).

Common Murre: Of the three most abundant seabirds, the Common Murre showed the strongest growth in population between 1979 and 1989 with a CAGR of 8.9% (Table 8). The population more than doubled in size between those two censuses, from 11 866 pairs in 1979 to 27 857 in 1989. From 1989 until the next census in 2002, however, the population increased only marginally to 28 664 pairs (CAGR of 0.2%) (Table 8). Across the Gulf of St. Lawrence, in the Migratory Bird Sanctuaries of the North Shore, between 1977 and 1988 annual growth was approximately 9% (Chapdelaine and Brousseau 1991) but between 1988 and 1998-1999 the population stabilized and the annual growth was <1.5% (Rail and Chapdelaine 2004). This was followed, however, by a 50% decline in the total murre population in the sanctuaries between 1998-1999 and 2005 (CAGR of -11.8%) (Rail and Cotter 2007). In both 1979 and 1989 there was only one murre colony on the Gaspé Peninsula, and that was on Bonaventure Island. In 2002 this colony was about the same size as it was in 1989 with 28 239 pairs (Table 7). There were, however, three new small colonies in 2002: Cap d'Espoir, Rocher Percé, and Forillon Peninsula (Table 7). Of these three new sites, Forillon contained the largest number of murres with an estimated 399 pairs.

Razorbill: Whereas the population of Common Murres increased considerably in size between 1979 and 1989 but then stablized, the population of this alcid doubled in size between each census. With 324 individuals in 1979, the Razorbill population increased to 634 in 1989 (CAGR of 6.9%) and then to 1 588 in 2002 (CAGR of 7.3 %) (Table 8). In all three censuses Razorbills were recorded at Bonaventure Island, Rocher Percé, and Forillon (Table 7). In 1989 and 2002 they also nested at Les Trois Soeurs and Cap d'Espoir (Tables 6, 7), and in 2002 three new small colonies were discovered, for a total of eight colonies that year. The Bonaventure Island colony accounts for ≥80% of the total Razorbill population on the Gaspé Peninsula. This percentage, however, has been declining, from 97% in 1979 to 87% in 1989 to 80% in 2002, despite the fact that this colony grew from only 307 birds in 1979 to 1 278 in 2002. As observed with many other species, the population of Razorbills along the St. Lawrence North Shore has shown a similar trend with the Gaspé population. In Migratory Bird Sanctuaries surveyed in that region at 5-6 year intervals, this alcid had annual growth of 8.6% and 7.3% for 1993 to 1998-1999 and 1998-1999 to 2005, respectively (Rail and Cotter 2007). In the St. Lawrence Estuary, the size and number of colonies have also been growing over the past 20 years (CWS, unpublished data).

Black Guillemot: The population of Black Guillemots on the Gaspé Peninsula has exhibited a consistent upward trend since 1979, with a CAGR of 4.1% for both 1979 to 1989 and 1989 to 2002 periods (Table 8). With such a rate of increase, this population has more than doubled in size between 1979 (2 033 pairs) and 2002 (5 167 pairs). The number of shoreline sectors where this alcid has been recorded during each of the three censuses has changed very little. In both 1979 and 1989 it was recorded at 16 sites, and this increased to 18 in 2002 (Table 8). For the first time, in 2002 a good-sized colony of guillemots was observed at Les Trois Soeurs. With 547 pairs, only Forillon Peninsula and the long stretch of coastline from Cloridorme to Marsoui harboured more guillemots. This little seabird is also doing well in the Migratory Bird Sanctuaries of the St. Lawrence North Shore, where the population has increased from 411 birds in 1993 to 924 birds in 2005 (Rail and Cotter 2007).

Atlantic Puffin: With the possible exception of the Leach's Storm-Petrel, this species is the least common of all seabirds on the Gaspé Peninsula. It is known to nest only on Bonaventure Island, where "a few pairs breed on the cliffs amid thousands of Northern Gannets and Common Murres" (Chapdelaine 1996). Breeding sites, probably hidden at the deep end of cliff ledges, cannot be counted, but small numbers (≤5 birds) of puffins were seen during each of the three censuses (Table 7).

Discussion

The first systematic seabird survey of the Gaspé Peninsula in 1979 recorded a population of approximately 134 000 birds. Over the next 10 years this population increased by 72% to just over 231 000 birds. During that decade, large increases in seabird numbers were also observed along the North Shore of the Gulf of St. Lawrence. Migratory Bird Sanctuaries in that region are censused every 5-6 years, and seabird populations within those sanctuaries increased by 65% between 1977 and 1982 (Chapdelaine and Brousseau 1984) and by 46% between 1982 and 1988 (Chapdelaine and Brousseau 1991). For both the Gaspé and the North Shore, the large increases in seabird populations in the 1980s may be attributed to increases in forage fish such as sandlance (*Ammodytes* spp.) and Capelin (*Mallotus villosus*) in the waters of the Estuary and Gulf of St. Lawrence, and the increase in the supply of forage fish may have occurred because of the decline in Cod (*Gadus morhua*) and other predator fish species due to overfishing (Chapdelaine and Brousseau 1991, 1992). Also, the decrease in some fishery activities may have resulted in reduced mortality of birds getting entangled in fishing gear. Finally, the consumption of seabirds and their eggs, often illegal, is probably a declining habit in local communities.

In the 1990s on the Gaspé Peninsula, however, the strong growth in the seabird population that occurred in the previous decade had slowed. Over the 13 years between the 1989 and 2002 censuses, the total population increased by only 21% to approximately 279 000 birds (Table 8). Similarly, seabird populations in Migratory Bird Sanctuaries along the St. Lawrence North Shore, which grew strongly in the 1980s, did not fare as well in the 1990s and early 2000s. In eight sanctuaries that were censused in 1988 and again in 2005, the total seabird population actually declined by 7% during that period (Chapdelaine and Brousseau 1991; Rail and Cotter 2007).

While most seabird species (11 of 14) on the Gaspé Peninsula exhibited similar trends between 1979 and 1989, that is, increases of >30%, this was not the situation between 1989 and 2002. Over this period, six of 14 species increased in population by ≥70%, three species decreased in numbers by >35%, and the populations of five remained relatively stable with changes of <15%. The latter group includes the Atlantic Puffin, for whom numbers are too low to assess changes in population size (Table 8).

In each of the 1979, 1989, and 2002 censuses, three species—Northern Gannet, Black-legged Kittiwake, and Common Murre—accounted for over 75% of the total population, and therefore changes in the populations of these species had the main impact on overall seabird population trends. Interestingly, between 1989 and 2002 these three species each exhibited a different trend; the population of the Northern Gannet increased by 122%, that of the Black-legged Kittiwake decreased by 13%, while the population of the Common Murre remained stable (increase of only 3%).

Of the different seabird groups, between 1989 and 2002 the total population of larids declined whereas the populations of alcids and cormorants increased. Three of the five larid species that breed on the Gaspé Peninsula declined sharply (>35%), whereas populations of all alcid and cormorant species either remained stable or increased. Of the remaining three individual species, Common Eiders and Northern Gannets increased in numbers, whereas the small population of Leach's Storm-Petrels declined (there were no active burrows found in 2002). Rail and Chapdelaine (2004) reported a similar pattern in the overall trends of seabirds along the St. Lawrence North Shore between 1993 and 1998-1999. Over that interval, they reported increases in population for four species, decreases for four species, and stable or moderate trends for the remaining species. As we observed on the Gaspé Peninsula in the 1990s, larids along the North Shore declined in numbers whereas populations of alcids and cormorants increased. It should be noted that among larids, the Ring-billed Gull was an exception to the downward trend; it increased considerably in numbers in both regions, with annual growth of 31.0% (1993 to 1998-1999) and 40.0% (1989-2002) for the North Shore sanctuaries (Rail and Chapdelaine 2004) and the Gaspé Peninsula, respectively. The coastlines of both regions are fronted by the Estuary and Gulf of St. Lawrence, which breeding seabirds of both regions use almost exclusively as their foraging grounds. It is not surprising, therefore, that the seabird populations of both regions show similar trends. Strong growth of Ring-bill populations also occurred in the Maritime Provinces, where the population grew at an annual rate of 20.9% between 1972 and 1986 (Lock 1988), and recent censuses in Prince Edward Island (Boyne and McKnight 2005) and New Brunswick (Boyne et al. 2006) have shown that populations in these two provinces have continued to grow.

An interesting observation from our results is the 1989-2002 trend for species that are "surface feeders" as compared with those that are "divers". The proportion of the total seabird population made up of divers increased from 50% in 1989 to 70% in 2002, and conversely the proportion for surface feeders fell from 50% to 30%. A similar pattern has occurred with seabird populations on the Magdalen Islands. In this archipelago, between 1989-1990 and 2000-2002 divers increased by 20% while surface feeders declined by 20% (CWS, unpublished data). This trend seems gen-

eralized throughout the Gulf of St. Lawrence, as within Migratory Bird Sanctuaries of the North Shore the same 20% increase in the proportion of diving species (and 20% decrease of surface feeders) can be noted between 1988 and 2005 (CWS, unpublished data).

For the Gaspé Peninsula, the recent declines in larids, in particular among kittiwakes and terns, as well as the possible extirpation of the Leach's Storm-Petrel, are major concerns for seabird biologists and managers. Factors that may be responsible for the declines, specifically possible changes in productivity, breeding conditions, predators, and/or survival, should be studied. Despite concern for these species, the overall population trends of seabirds along this peninsula are encouraging. The total number of seabirds has doubled between the first comprehensive survey in 1979 and the most recent survey in 2002, with nine of the 14 breeding seabirds showing strong population growth over that period.

Acknowledgments

We extend special thanks to our recently retired colleague, Gilles Chapdelaine, who in addition to having organized and carried out the field work for this third seabird census of the Gaspé Peninsula is largely responsible for the development in Québec of a modern seabird monitoring program. We also thank Jean-François Cloutier, personnel from the Parc national de l'Île-Bonaventure-et-du-Rocher-Percé and Forillon National Park of Canada, and Serge Brodeur for their assistance in the surveys. John Chardine was of great assistance with the gannet survey.

Sixteenth Census of Seabird Populations in the Sanctuaries of the North Shore of the Gulf of St. Lawrence, 2005

JEAN-FRANÇOIS RAIL and RICHARD COTTER

Canadian Wildlife Service, P.O. Box 10100, Ste-Foy, Québec G1V 4H5 Canada

Rail, Jean-François, and Richard Cotter. 2007. Sixteenth census of seabird populations in the sanctuaries of the North Shore of the Gulf of St. Lawrence, 2005. Canadian Field-Naturalist 121(3): 287-294.

The Migratory Bird Sanctuaries of the North Shore of the Gulf of St. Lawrence are important breeding grounds for many seabird species. The quinquennial censuses of seabirds in these sanctuaries have been carried out for 80 years (since 1925), in order to detect changes in the distribution and population levels of seabirds breeding on the North Shore. Between 1998-1999 and 2005, the most striking trends observed were the near doubling in numbers of Common Eiders in most sanctuaries, and the strong population growth rate of Razorbill. Unexplainable declines of Common Murre and Atlantic Puffin were observed at some of the larger colonies of these species. The last active colonies of Leach's Storm-Petrel (Corossol Island) and Caspian Tern (Île à la Brume) on the North Shore seem on the verge of disappearing, with zero and three birds observed in 2005, respectively. Seabird populations in the larger, more accessible and disturbed sanctuaries are still markedly smaller than in historical times.

Les refuges d'oiseaux migrateurs de la Côte-Nord du Golfe du Saint-Laurent constituent d'importants sites de nidification pour plusieurs espèces d'oiseaux marins. Des inventaires quinquennaux des oiseaux marins dans ces refuges sont effectués depuis 80 ans (depuis 1925), pour détecter les changements dans la répartition et les niveaux de population des oiseaux marins nichant sur la Côte-Nord. Entre 1998-99 et 2005, les tendances les plus marquantes étaient chez l'Eider à duvet, dont les effectifs ont pratiquement doublé dans la plupart des refuges, et chez le Petit Pingouin, dont les populations ont également connu une croissance rapide. Des déclins énigmatiques chez le Guillemot marmette et le Macareux moine ont été observés à plusieurs des colonies les plus importantes de ces espèces. Les dernières colonies actives d'Océanite cul-blanc (à l'île du Corossol) et de Sterne caspienne (à l'île à la Brume) sur la Côte-Nord semblent sur le point de disparaître, avec respectivement zéro et trois oiseaux observés en 2005. Les populations d'oiseaux marins demeurent à des niveaux bien en-deçà de ceux rapportés historiquement dans les refuges de grande superficie, davantage accessibles et sujets au dérangement.

Key Words: Seabirds, populations, sanctuaries, Atlantic Puffin, larids, alcids, Gulf of St. Lawrence.

The Migratory Bird Sanctuaries of the North Shore of the Gulf of St. Lawrence not only contribute to seabird conservation by protecting important breeding grounds, but through the quinquennial censuses they serve as monitoring areas to detect changes in the distribution and population levels of 15 species of seabirds (scientific names given in Table 1), which in turn orient future research and management.

Since the creation of the sanctuaries on the North Shore in 1925, seabirds breeding in these sanctuaries have been censused approximately every five years. The results of previous surveys have been consistently published (Lewis 1925, 1931, 1937, 1942; Hewitt 1950; Tener 1951; Lemieux 1956; Moisan 1962; Moisan and Fyfe 1967; Nettleship and Lock 1973; Chapdelaine 1980, 1995; Chapdelaine and Brousseau 1984, 1991; Rail and Chapdelaine 2004). Thus the sixteenth census, conducted in 2005, perpetuated an 80 year-old tradition that constitutes, over time, an invaluable database for the management and conservation of seabird populations in Québec. For some species, a very significant proportion of their total breeding population in the province is found in North Shore Migratory Bird Sanctuaries. Furthermore, many species are represented well enough in these sanctuaries to assume that the observed population trends reflect the demographic changes for the entire North Shore. These censuses of seabird colonies are of even greater importance as for most of our seabirds they are the only means to effectively monitor population trends, because most seabird species are not currently covered by other existing monitoring programs. Ultimately, the integrity of the whole seabird community in the sanctuaries can also be used as a sentinel to track environmental changes and to evaluate the health of the Gulf of St. Lawrence marine ecosystem.

The goals of this article are to update population estimates and trends for seabirds breeding in the ten Migratory Bird Sanctuaries of the North Shore of the Gulf of St. Lawrence, to evaluate the situation of each species, and to identify priority issues for their conservation.

Methods

We used basically the same survey techniques as in 1998-1999 (see Rail and Chapdelaine 2004). The methodology, described in detail for each species and site in Rail and Chapdelaine (2002), is summarized below for each family of birds.

ANATIDS — On Corossol Island, the average nest density (nests/ha) as calculated from six 60 m × 60 m (0.36 ha) quadrats, was extrapolated to the entire area

on the island deemed suitable for Common Eiders (Chapdelaine 1978*). In the Betchouane Bird Sanctuary, we used a system of line-transects of varying length on Innu Island and conducted a systematic nest count elsewhere. In Watshishou and Île à la Brume, we counted all eider nests on the same sample of islands used in previous censuses, which covered 12% and 27% of the sanctuaries' land area, respectively, and we then extrapolated the average density over the entire area encompassing all the islands. At the Baie des Loups Sanctuary, a combination of methods was used: average nest density was extrapolated from two quadrats on Île Les Blacklands, from a sample of islands at Îles Factory, and from the closest island at Île no 4; the remaining islands in the sanctuary were systematically censused. Total nest counts were conducted on most large islands at the Îles aux Perroquets and Îles Sainte-Marie Sanctuaries, representing 57% and 96% of the total land area, respectively; average nest densities were extrapolated to the rest of the sanctuaries. At the Gros Mécatina and Saint-Augustin Sanctuaries we also searched for nests on the largest islands, but for the smaller islands, on which we did not land, we counted from a boat all females that flushed and assumed one nest per female observed.

GAVIIDS — Red-throated Loon nests were systematically counted by walking around the ponds on islands presenting suitable open habitat in each sanctuary. In one instance, instead of landing on the island, we noted the presence of a territorial adult.

HYDROBATIDS — We systematically searched for active burrows where colonies had been found in previous censuses. Traditionally, a burrow was considered active if we detected signs, such as soil freshly excavated and/or oily odour characteristic of petrels, or when we were able to reach an adult inside the burrow. In 2005 we also used in some instances a burrow probe (Peep-A-Roo, Sandpiper Technologies Inc.), which consisted of a 1.0-inch diameter video imager with infrared illumination source, on a 3-meter long flexible cord.

PHALACROCORACIDS — Great and Double-crested Cormorant nests were systematically either from the ground, from a lookout point, or from a boat.

LARIDS — On Corossol Island, we counted the number of nests (Np) and the number of adults (Ni) in subcolonies, then we estimated the number of pairs in sectors where we counted only the number of adults present by using the factor k (k = Np/Ni). In these sectors we applied the observed species ratio (Great Black-backed / Herring Gulls) to the calculated number of nests. All gull nests were counted systematically at the Betchouane Sanctuary, and attributed to Herring and Great Black-backed Gulls afterwards according to the observed proportions of adults of both species. A combination of nest counts, adult counts and species ratios was used elsewhere for gulls and terns, except that results have been combined for Arctic and Common Terns in Table 1. For the Black-legged Kittiwake, we counted apparently occupied nests.

ALCIDS — Adult bird counts were used to estimate Black Guillemot populations in all sanctuaries. When colonies of Common Murres, Razorbills and Atlantic Puffins could be visited with minimal disturbance, we systematically counted the eggs and apparently active burrows. For puffins, we occasionally used the Peep-A-Roo burrow probe (described in the Hydrobatids survey method) to determine the real occupancy rate of apparently active burrows. At many colonies, for example, burrows that were inaccessible in cliffs or featuring large numbers of birds (especially murres), we avoided disturbance by counting from a distance all individuals at the colony and on nearby waters, using binoculars or a spotting scope. At Corossol Island and Gros Mécatina Sanctuaries, only bird counts were used, whereas all eggs and active burrows were noted at the Betchouane Sanctuary. Population estimates for the large concentrations of alcids at the Baie des Loups, Îles aux Perroquets and Îles Sainte-Marie Sanctuaries were obtained mostly from adult counts. For Atlantic Puffins nesting in the Baie des Loups Sanctuary, we used the method described above for larids, that is we calculated the factor k (number of active burrows per individual observed at the colony) for sectors on Île Les Blacklands and Île du Loup and used it to estimate the number of pairs for puffins observed elsewhere. Evenly spaced grids and line transects were used on Île aux Perroquets in the Baie de Brador Sanctuary, in order to (1) delimit the area of both the puffin and Razorbill colonies, (2) evaluate mean nest densities, and (3) extrapolate the calculated density to total colony area (*see* Nettleship 1973* ; Chapdelaine 1978*). Incubating murres were counted on this same island. Also, in the Baie de Brador Sanctuary, numbers of puffins around L'Île-Verte were counted.

Results

The number of seabird species breeding in North Shore sanctuaries remained at 14 between 1998-1999 and 2005, with the reappearance of the Caspian Tern (3 adults) at the Île à la Brume Sanctuary, and the apparent disappearance of the Leach's Storm-Petrel. If we exclude results from the Saint-Augustin Sanctuary (not surveyed in 1998-1999), the estimated total number of breeding seabirds censused in 2005 (n = 107 011 individuals) was very similar to 1998-1999 estimate (n = 103 579; increase of only 3.3%). However, some species showed marked population changes (Tables 1 and 2). In particular, Common Eider numbers doubled in nearly every sanctuary. The Razorbill population also increased greatly in most sanctuaries (overall annual growth rate of +7.3%). On the other hand, the population of Common Murres dropped by half between 1998-1999 and 2005.

[1] Important note: it is more than likely that the calculation method used to estimate the eider population in Watshishou results in a significant overestimation (by possibly as much as 3-4 times, but see Rail and Chapdelaine 2002). The reason we used this method was for population trends analysis, e.g. to allow better historical comparisons (results were obtained with the same method in previous censuses).

[2] In 2005, the use of the burrow probe at a few sites at Baie des Loups, Îles aux Perroquets and Baie de Brador verified that apparently occupied burrows were actually used at a fairly constant rate (between 74 and 76%. Thus the puffin populations estimates presented here for these sanctuaries, and for the Îles Sainte-Marie Sanctuary as well, are overestimations because apparently occupied burrow counts were used. We did not apply a correction factor to these estimates so as to be able to better compare with data from previous censuses.

TABLE 2. Changes in the numbers of seabirds in sanctuaries on the North Shore of the Gulf of St Lawrence, Québec, 1993 to 2005.

Species	Years of survey rate by period*			Compound annual growth	
	1993	1998-1999	2005	1993-1999**	1999-2005**
Common Eider	14548	13072	25570	-2.10%	9.98%
Red-throated Loon	66	82	92	3.21%	1.92%
Leach's Storm-Petrel	1840	718	0	-18.38%	-100.00%
Double-crested Cormorant	3472	2830	3346	-3.36%	2.82%
Great Cormorant	78	342	48	24.54%	-32.73%
Ring-billed Gull	104	484	1344	28.43%	21.54%
Herring Gull	4879	4988	4812	0.58%	-0.27%
Great Black-backed Gull	2284	2427	1870	1.27%	-3.79%
Black-legged Kittiwake	6294	3856	3994	-9.98%	0.64%

Atlantic Puffin	46684	29133	25335	-7.91%	-2.34%

$$*r = \frac{\log_e N(t) - \log_e N(o)}{t} \; 100\%$$

** Data from the Saint-Augustin Sanctuary (censused only in 2005) are excluded from this table, as well as data from the Gros Mécatina Sanctuary (not surveyed in 1993) in the 1993-1999 growth rate calculations. Populations in sanctuaries censused in 1998 were extrapolated to 1999 to derive the compound annual growth rate for all North Shore sanctuaries after 6 years.

Although smaller murre colonies grew substantially in size, the bulk of the population, concentrated at Îles Sainte-Marie and Îles aux Perroquets, suffered an unexplainable and severe decline. In other respects, the sharp decreases in Black-legged Kittiwake numbers that were noted in 1993 and 1998-1999 had finally ceased by 2005 at Corossol Island, the largest colony on the North Shore. The 2005 census also showed that Herring Gull populations were quite stable, whereas Great Black-backed Gulls suffered a 23% overall reduction in numbers compared with 1998-1999. All major Atlantic Puffin colonies showed declines except for the Baie de Brador colony which increased by 27%, and this colony thereby represents the only stronghold of the species in our province.

Corossol Island was visited from 28 May to 30 May. In 1998, the island held the last known colony of Leach's Storm-Petrel on the North Shore (359 active burrows). Unfortunately, no nests were found in 2005. The Double-crested Cormorant colony had 156 nests in 2005, which is only a third of its size in 1998. Conversely, the estimated 980 breeding pairs of Common Eiders in 2005 represent a 69% increase compared to the 1998 count. We found that the rapid decline of Black-legged Kittiwake numbers, noted during the two preceding censuses, had finally stopped between 1998 and 2005. This species is still the most abundant seabird on the island. Alcids in general showed clear upward trends, in particular the Razorbill population which increased by 170% during the 1998-2005 period. Finally, Herring and Great Black-backed Gulls numbers were somewhat reduced in 2005, shrinking back to the levels observed in 1993. The total number of breeding seabirds was similar in 1998 and 2005 at Corossol Island.

On 2 June 2005 the Betchouane Sanctuary was surveyed and Common Eider numbers were found to have had increased by 81% compared to 1998. The observed density of nests was impressive as over one-fifth (21.8%) of the eiders breeding in all North Shore sanctuaries were concentrated in Betchouane, the smallest sanctuary. Alcids also did well between 1998 and 2005; numbers of Razorbills and Atlantic Puffins had risen significantly, and the 64 Common Murre pairs discovered in 2005 were the first breeding record of this species in the sanctuary. Population levels of gulls and kittiwakes were quite stable between 1998 and 2005. The overall number of breeding seabirds increased by more than 60%.

When we visited the Watshishou Bird Sanctuary on 4 and 5 June 2005, we found the Common Eider population had literally exploded since 1998 (+132%). The terns had bounced back with an estimated 331 individuals breeding on ten islands, after very few of these birds were seen in 1998 (n = 38). Three of the four Double-crested Cormorant colonies found in 1998 had grown in numbers in 2005 (+56.6% total increase). Numbers of Herring and Great Black-backed Gulls stayed remarkably stable during the same period. On the other hand, Black Guillemots were less abundant in 2005 than in 1998, and no Razorbills were seen in 2005.Population trends between 1999 and 2005 were

FIGURE 1. Location of the sanctuaries of the North Shore of the Gulf of St. Lawrence.

minor for most species breeding at the Île à la Brume Sanctuary. Even Common Eiders were stable here, whereas spectacular increases were noted for this species in other sanctuaries. The Caspian Tern did a timid comeback with three (presumably) breeding individuals seen in 2005. This species had not been recorded on the two previous quinquennial censuses. Conversely, for the first time since the beginning of the quinquennial censuses in 1925, no Razorbills were seen in this sanctuary in 2005. Only Herring and Great Black-backed gulls exhibited marked positive trends; their small populations grew more than twofold between 1999 and 2005. The Île à la Brume Sanctuary was visited on 9 and 10 June.

The most striking result for the Baie des Loups Sanctuary (visited on 11, 14 and 19 June) was the extremely low number of Atlantic Puffins observed at Île Les Blacklands, an island which has always been well known for its large puffin colony. Data analysis confirmed the catastrophic puffin decline (-79%) between 1999 and 2005 in this sanctuary. Since 1960, the Baie des Loups Sanctuary had never held less than 25% of the total puffin population breeding in North Shore sanctuaries, until this proportion dropped to 7% in 2005. Black Guillemots also had suffered a sharp decline (-75%). Razorbill numbers were similar in 1999 and 2005, in contrast with the general upward trend observed elsewhere for this species during the same period. On the bright side, the small Common Murre population had become firmly established in the sanctuary in 2005 with a near fivefold increase since 1999, and with the appearance of a second colony. Meanwhile, the population of Common Eiders had also risen substantially (+87%).

At the Îles aux Perroquets Sanctuary, the total number of breeding alcids stayed relatively stable between 1999 and 2005, but this is because the Razorbills' large population increase (+172%) compensated for the declines in Common Murres (-56%), Atlantic Puffins (-61%) and Black Guillemots (-39%). The Common Eider population grew by +80%. Meanwhile, Herring and Great Black-backed Gull numbers were nearly stable. Only one of the seven Great Cormorant nests found in 1999 was still active in 2005. Black-legged Kittiwakes seemed also on the verge of disappearing from Îles aux Perroquets, with seven nests left in 2005. The sanctuary was visited on 13 and 22 June.

The Îles Sainte-Marie Sanctuary comprises large islands that hold important concentrations of seabirds, and six days were devoted to their census (15, 17, 18, and 20 to 22 June) in 2005. Alcids showed moderate population trends except for the major drop in Common Murre numbers (-54%), the most abundant seabird in the sanctuary. There were more than twice as many eider nests as in 1999. Between 1999 and 2005, the Black-legged Kittiwake colony at Île Cliff grew unexpectedly (+184%), but other gull populations continued to dwindle in the sanctuary. Such low numbers of breeding Great Black-backed and Herring Gulls had not been seen there since 1950 and 1925, respectively.

The two species of cormorants showed opposite trends. With an 86% drop between 1999 and 2005, the size of the Great Cormorant colony in 2005 (23 nests) was the smallest ever recorded since its establishment in the early 1930s, whereas the Double-crested Cormorant colony increased to 650 nests (+62%).

The Gros Mécatina Sanctuary was surveyed in two stages: the Îles aux Marmettes and Île Plate were visited on 23 June, whereas Île aux Trois Collines could not be accessed before 7 July. This was only the second quinquennial survey of the Gros Mécatina Sanctuary, which was created in 1996. In 2005, two species had disappeared (Great Cormorant, Black-legged Kittiwake) but were replaced by two others (Double-crested Cormorant, Common Eider). The most significant change was in the tern colony at Île Plate which grew from 50 to nearly 900 pairs between 1999 and 2005. Terns now comprise two-thirds of all breeding seabirds in the sanctuary. Also, the small number of Common Murres observed had increased fivefold. Considering the small size of the sanctuary, the growth (+75% between 1999 and 2005) and size (n = 240 in 2005) of the Black Guillemot population were impressive.

Our visit to the Saint-Augustin Sanctuary on 25 June 2005 was the first in 17 years. The last time was at the end of the 1980s, when Herring Gull populations were thriving, and just before a widespread decline was observed on the North Shore. The 2005 census confirmed that this trend also occurred at the Saint-Augustin Sanctuary, as Herring Gull numbers were down 82% compared with 1988. The Great Black-backed Gull population also suffered a 73% decline during the same period. Alcids, represented by a mere four (4) Black Guillemots in 2005, did not show any signs of recovery. Common Eiders, on the other hand, made a noticeable comeback as they were more than ten times more abundant than in 1988. However, considering that the Saint-Augustin Sanctuary has the largest land surface area of all North Shore sanctuaries and the fact that between 1935 and 1960 a minimum of five hundred pairs of eiders were recorded in any one census, the estimate of 73 pairs for 2005 looks far from the potential of these islands. The terns, though, were well represented in 2005, with numerous (n = 13) colonies and a total population of nearly a thousand birds, the largest ever recorded in this sanctuary.

The largest concentration of breeding Atlantic Puffins in the province of Québec has always been located in the Baie de Brador Sanctuary. Fortunately, our results show a 27% increase of that colony between 1999 and 2005, in contrast with the declines observed at other major puffin colonies on the North Shore. Baie de Brador now shelters 79% of all puffins breeding in North Shore sanctuaries. During the same period, the Razorbill population mean annual growth rate was high (6.9%) but similar to elsewhere, and numbers of Common Murres went up by an amazing 50% annually. In other respects, the colony of Black-legged Kittiwakes discovered in 1999 had already disappeared by 2005. We landed on Île aux Perroquets on 30 June and 1 July, whereas L'Île-Verte could not be reached before 12 August.

Discussion

Here we present a short analysis of the latest population trend and current status of each species in the North Shore sanctuaries, in order of species in best health (population) to worst. The Common Eider has to come first on the list. Its population has increased dramatically since 1982, and the near-doubling in numbers between 1998-1999 and 2005 represents a very strong population growth rate. The Common Eider is now the most abundant breeding seabird in North Shore sanctuaries. The Razorbill is another species that has been increasing in numbers for more than 20 years in the sanctuaries (as well as everywhere in Eastern North America, Chapdelaine et al. 2001), and there is no indication that this upward trend will slow. Furthermore, many new colony sites were discovered during this period. The size of the Red-throated Loon population was larger than ever in 2005, particularly due to the high numbers reported in the Îles Sainte-Marie and Îles aux Perroquets sanctuaries. The addition of the latter sanctuary in 1982 helped to protect a significant proportion of this species' small population of only a few hundred individuals spread along the northern coasts of the Gulf of St. Lawrence (DesGranges and Laporte 1979*; Barr et al. 2000; Chapdelaine and Rail 2004). The Black Guillemot has also fared well in the sanctuaries, an exception being at Île à la Brume and Baie des Loups, where breeding numbers have been much higher in the past. Important for the species is the recently created Gros Mécatina Sanctuary (1996); this sanctuary encompasses less than 3% of the total land surface area of North Shore sanctuaries yet it harboured one-fourth of the Black Guillemot population in 2005. The Double-crested Cormorant, the Common and Arctic Tern, and the Ring-billed Gull were species very well represented in North Shore sanctuaries in 2005. However, the trends observed with these species in the sanctuaries may not be representative for the whole North Shore. In fact, the few colonies of Double-crested Cormorants in the sanctuaries show variable and sometimes contrasting trends. And colonies of terns and Ring-billed Gulls are highly unpredictable, too variable in size and localization (in and out of the sanctuaries from one year to another) to derive meaningful trends.

Herring Gull population trends also tended to vary between sanctuaries, but as a whole the North Shore population has been quite stable since the crash that occurred between 1988 and 1993 (which was associated with the collapse of the cod fishery, see Chapdelaine and Rail 1997). In 2005 the species was well established in all sanctuaries. Great Black-backed

Gulls were also well represented in every sanctuary, and leaving aside the 43% decline at Corossol Island, elsewhere the population was stable between 1998-1999 and 2005. Another species showing relative stability in numbers between the last two quinquennial censuses is the Black-legged Kittiwake. At Corossol Island, the only large colony in North Shore Sanctuaries, the sharp declining trend (-58%) observed between 1988 and 1998 had ceased by 2005. Because of this colony's importance for the species on the North Shore and evidence of very poor reproductive success in 2005 and 2006 (CWS, unpublished data), it is imperative that careful monitoring of the colony occurs in the future. Examination of their diet suggests that when staple food (capelin, sandlance) becomes scarce in their diet, the larger gulls (Herring and Great Black-backed gulls) are more likely to prey on kittiwake chicks.

The Common Murre population had expanded so much between 1972 and the 1990s that it was disappointing to see this recent setback (51% decline between 1998-1999 and 2005) which brought the population back to the level observed in 1982. The Common Murre is still the fourth most abundant bird in the sanctuaries, but the underlying factors responsible for the substantial population decline at the largest colonies are not known and will need to be investigated if the species declines in number any further. The Îles Sainte-Marie holds the only well-established Great Cormorant colony in North Shore sanctuaries. The number of nests, which once peaked at 339 (in 1955), has been highly variable since 1993. We can only hope that numbers will bounce back after the lowest number of nests ever recorded there was in 2005, otherwise the species may well disappear from the sanctuaries in the near future. The Atlantic Puffin is not on the verge of vanishing from the sanctuaries; however, its situation is worrying, as the larger colonies located at Baie des Loups, Îles aux Perroquets, Îles Sainte-Marie and Baie de Brador declined by 47% between 1993 and 2005. The 79% decline in six years (1999 to 2005) at Baie des Loups is particularly mysterious, and the colony at the Baie de Brador sanctuary, currently the species' stronghold in the province of Québec, appears vulnerable to disturbance, poaching and bycatch in fishing nets. The fact that three Caspian Terns were observed in 2005 in the Île à la Brume Sanctuary, the only active breeding site in the province, confirms that a small number of individuals of this species continues to frequent the area. We suspect that a few pairs may still breed there sporadically, but it is doubtful that such a tiny population can persist for long if no recovery plan is implemented (but see Shaffer et al. 2004). The first active burrows of Leach's Storm-Petrels were discovered in 1972 in the Baie des Loups Sanctuary. In the censuses that followed, the species was found in three other sanctuaries, with a total of close to 900 burrows in 1982 and 1988. Inexplicably, storm-petrels vanished as fast as they appeared and in 2005 not a single nesting site was found at the last active colony, Île du Corossol. We have no reason to believe that the (unknown) factors responsible for the loss of this species will be reversed in the future.

We identified sanctuaries that seemed in worse shape by comparing the 2005 seabird numbers with historical data in each sanctuary. Some current seabird populations estimates are markedly lower than in historical times. For example, the Île à la Brume Sanctuary once protected a fair number of alcids, including up to 2000 pairs of Common Murres (in 1935). These species declined and never recovered, and in 2005 only a few pairs of Black Guillemot were still breeding in the sanctuary. Alcid populations had also been much larger in the past at the Baie des Loups Sanctuary. At the Saint-Augustin Sanctuary, population levels of Common Eider, Black Guillemot and Red-throated Loon seem far from the potential showed in the 1940s. Moreover, while the Île à la Brume and Saint-Augustin Sanctuaries together represent 40% of the total land area of the ten North Shore sanctuaries, only 4.1% of the seabirds were found there. Of course, seabird populations also reflect habitat features, and these two sanctuaries may not have habitats such as cliffs and deep crevices that are most suitable for kittiwakes and murres. But even the Common Eider, which in 2005 was abundant in similar habitat in Watshishou, was rather rare in the Île à la Brume and Saint-Augustin sanctuaries as they harboured only 2.2% of the total North Shore sanctuaries population. Besides, we saw evidence of eider egg collection in the Saint-Augustin sanctuary in 2005. In these sanctuaries that are comprised of a large number of islands and are easily accessed by boat from nearby villages, the poor density of breeding birds is likely the result of a lack of law enforcement and public awareness the vulnerability of seabird breeding colonies. In addition to improvements in law enforcement and educational programs in local communities, priorities for seabird conservation in North Shore sanctuaries should include population studies to identify the underlying causes of the unexplained declines in Atlantic Puffins and Common Murres and a restoration project for the Caspian Tern colony at Île à la Brume.

Acknowledgments

Many thanks to everyone who contributed to this census. First, our special thanks go to the Gallienne family for their hospitality on Corossol Island. Fieldwork was carried out with the help of our colleagues Pierre Brousseau, Renaude Bender, Jocelyn Thibault, Raphaël Lavoie and Olivier Meyer, as well as Canadian Wildlife Service game wardens Wilson Evans and Mathieu Nadeau-Monger. Members of Parks Canada in Havre Saint-Pierre, Louis Lalo and many volunteers also gave us a big hand at the Betchouane and Watshishou sanctuaries. Dean and Peggy Martin helped us

to renew the traditional survey of the Saint-Augustin Sanctuary, which their late father, Canadian Wildlife Service game warden Londus Martin, had patrolled for so many years. We would also like to acknowledge Trish Nash and Tess Cecil-Cockwell from the Quebec-Labrador Foundation for their efforts at Baie de Brador and Saint-Augustin sanctuaries, as well as boatmen Lawrence Jones and his son Edward Jones at Blanc-Sablon.

Catling, Paul M., and Bruce A. Bennett. 2007. Discovery a possibly relict outbreeding morphotype of Sparrow's-egg Lady's-slipper Orchid, *Cypripedium passerinum*, in southwestern Yukon. Canadian Field-Naturalist 121(3): 295-298.

An outbreeding morphotype of *Cypripedium passerinum* with separate anthers and stigma was discovered in the Beringian region of southwesternYukon. The occurrence of this breeding system in Beringia is attributed to the persistent advantage of outbreeding over hundreds of thousands of years in this unglaciated area, whereas the widespread occurrence of exclusively self-pollinating races elsewhere in Canada is attributed to advantages in colonization of recently deglaciated territory which first became available less than 10 000 years ago, and/or to a changing and more forested habitat.

Key Words: Sparrow's-egg Lady's-slipper Orchid, *Cypripedium passerinum*, Orchidaceae, autogamy, self-pollination, unglaciated, Beringia, Kluane, Yukon.

In fresh flowers of Sparrow-egg Lady's-slipper Orchid (*Cypripedium passerinum* Richards.), the lateral parts of the stigma are in contact with the anther allowing self-pollination (Figure 1A). Self-pollination is evident by a mass of pollen tubes connecting the expanded anther tightly to the stigmatic surface. It occurs when the flowers are still in bud or before they are fully open and germination of pollen prevents subsequent removal by pollinators resulting in little chance for cross-pollination. This obligate self-pollination is widespread (Catling 1983; Catling, personal observation) in the geographic range, which extends from Quebec west across the boreal forest and montane region of Canada to Alaska (Sheviak 2002; Figure 2). Plants that do not self-pollinate have not been observed prior to the observations reported here.

An examination of long-faded and shrivelled flowers, clearly past peak flowering, collected in alcohol on 13 July 2006 from the Alsek River trail (60.7748°N, -137.6939°W, approximately 10 km west of Haines Junction) in the Kluane Range, St. Elias Mountains of southwestern Yukon, revealed that self-pollination had not occurred in 7 of 8 flowers removed from a clump of 30. In most of these flowers self-pollination was prevented because the anthers were clearly separated from the stigmatic surface (Figures 1B-C) but in one flower they were touching but without self-pollination (Figure 1D) and the anthers were bowed so that most of the length of the suture was not in contact with the stigmatic surface. In one of these flowers self-pollination had occurred apparently due to contact of anther and stigma (Figure 1E). All eight of the flowers from this clump were presumably from one individual and suggest variation in self-pollination at the individual level. A voucher specimen (*Catling & Bennett*, 13 July 2006) from the Alsek River location has been placed in the National Collection (acronym — DAO) of Agriculture and Agri-Food Canada on the Central Experimental Farm in Ottawa.

Ten long-faded flowers collected from several individual plants south of Whitehorse at Cowley Creek (60.5908°N, 134.8953°W) were self-pollinated (Figures 1F-H) and so were three flowers collected from a location near Mayo (not illustrated). In one of the flowers from Whitehorse an anther was sufficiently separated that self-pollination had not occurred (Figure 1F). Although only the distal tip of the anther suture appeared to contact the stigmatic surface in most specimens, in one flower (Figure 1G) the proximal part had also come in contact, with the result that pollen tubes entered the stigma from both anther tips. Self-pollination in orchids is frequently partial or facultative (e.g., Catling 1990). In western Yukon there may be substantial variation in column morphology leading to variation in amounts of self-pollination, both within individuals and between plants. This variation may have provided the basis for the selection of obligate self-pollinating morphotypes that are now widespread.

Selection for self-pollination may have favoured a number of characteristics including: (1) more extensive development of the lateral parts of the stigmatic surface; (2) less divergence of the anther stalks; (3) less elongation and curvature of the column resulting in less displacement of the anthers above the stigmatic surface; (4) increased bowing of the anthers to bring the tips of the suture into contact with the stigmatic sur-

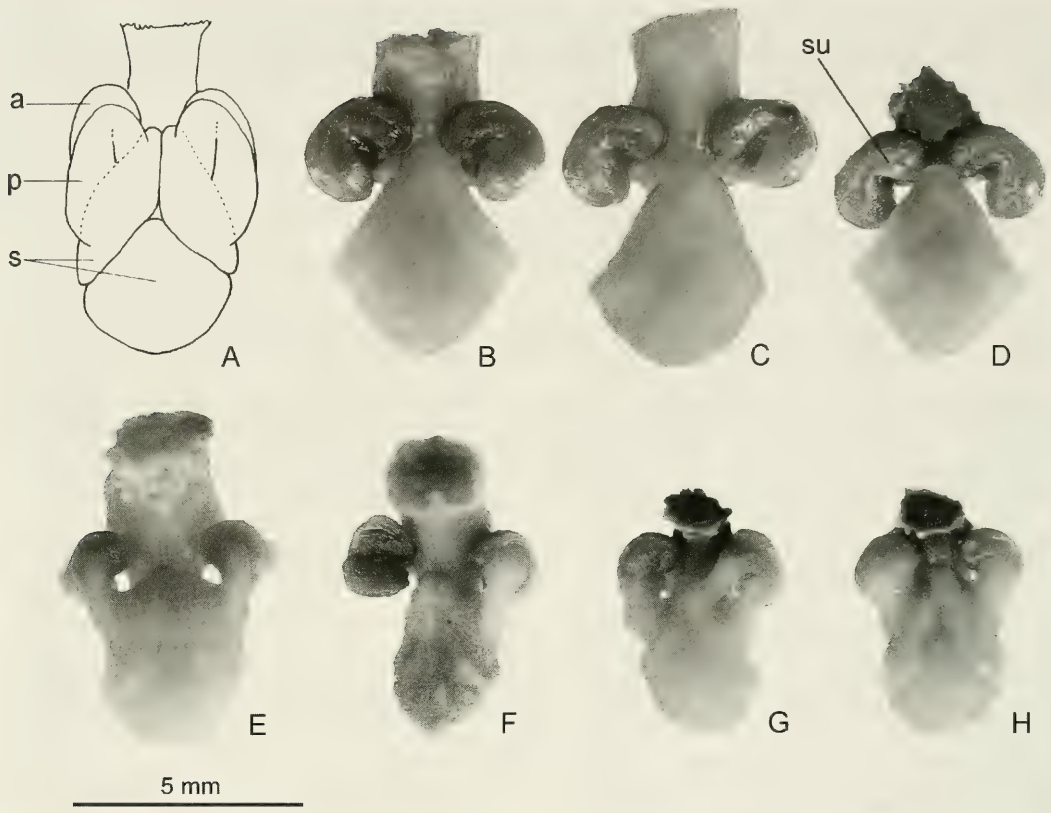

FIGURE 1. Columns of *Cypripedium passerinum* viewed from below showing anthers (a), pollinia (p), stigmatic surface (s) and suture of anther (su). A, camera lucida drawing of flower from Hattie Cove, Lake Superior, Ontario (modified from Catling 1983); B-E flowers from Alsek trail, Kluane Range, Yukon; F-H, flowers from south of Whitehorse, Yukon. Columns A and E-H demonstrate self-pollination with one or both anthers connected to the stigmatic surface by a mass of pollen tubes. Columns B-D have not self-pollinated.

face; and (5) increased secretion of stigmatic fluid which would connect the anther and the stigma. Regardless of how the flowers have changed to promote self-pollination, both the separation of anther and stigma, and the lack of self-pollination in old flowers are novel observations suggesting outbreeding in a species that was hitherto known only to obligately self-pollinate.

The structure related to breeding system in *C. passerinum* is difficult to discern in reconstituted pressed herbarium specimens and softening the few flowers on a specimen to evaluate it results in damage to the specimen. As a consequence, an investigation of herbarium material was not conducted. The examination of fresh plants from at least 20 localities (Catling, personal observation) across Canada, including Ontario (3 locations), Manitoba (1 location), British Columbia (8 locations), Alberta (2 locations) and Northwest Territories (6 locations) is believed to reliably indicate the predominance of the obligately self-pollinating morphotype outside of the Beringian region (Figure 2). Nevertheless, more research on the geographical occurrence and related morphological and anatomical aspects is needed to better understand the evolution of self-pollination in this species, and to provide a basis for consideration of formal taxonomic recognition.

Self-pollination originates through evolution by natural selection from cross-pollinated plants (e.g., Catling 1990). In general, self-pollination in orchids is more frequent in cooler and more extreme environments such as recently glaciated territory (Catling 1983, 1990). This is believed to be a consequence of strong selection for colonizing ability, the selfing plants being able to set seed in the absence of others of their kind and/or in the absence of pollinators and being able to mass produce adapted genotypes. This would have been advantageous in colonizing huge areas of land (most of northern North America) exposed following melting of the Wisconsin ice sheets less than 10 000 years ago (Dyke 2005). It may also be advantageous within Beringia as a consequence of the change from pollinator-rich willow (*Salix* spp.) scrub and tundra to

FIGURE 2. Distribution of *Cypripedium passerinum* in northwestern North America (dots) and location of plants with non-auto-pollinating column structure on Alsek River (circle). The unglaciated region of Beringia is darkly shaded (redrawn from Dyke 2005). The dot distribution of *C. passerinum* was copied from Cody (1996), Hultén (1968), Packer (1959), Porsild and Cody (1980), and Szczawinski (1959).

a pollinator-depauperate boreal forest that occurred between 9000 and 5000 ka kiloannum BP (Dyke 2005). As a result of the strong selection, self-pollinating morphotypes are presumed to have evolved from cross-pollinated ancestors in unglaciated territory, and these new selfers spread over the newly available or recently changed landscape. Many self-pollinating orchids have a non-self-pollinating relative that has a more restricted range in a region of more temperate climate and/or longer established habitat. Examples in North America include self-pollinating *Liparis loeselii* which is widespread north of the range of the non-self-pollinating *Liparis liliifolia*, and self-pollinating *Spiranthes ovalis* var. *erostellata* which is widespread north of the more restricted distribution of *Spiranthes ovalis* var. *ovalis* (see Catling 1990 for other examples).

The occurrence of a non-self-pollinating race of *Cypripedium passerinum* in the northwestern part of the range rather than the warmer southern or southeastern part of its range is at first contrary to expectation. However, in this example a relict outbreeding morphotype may have existed for hundreds of thousands of years in the unglaciated Beringian area of Alaska and western Yukon (Figure 2 and see Scudder 1997). It may have been from this source that morphotypes more committed to self-pollination spread southward and eastward following deglaciation 10 000 years ago. The present distribution of *Cypripedium passerinum* fits what Hultén refers to as "North American boreal plants radiating from Beringia." (Hultén 1937, see also Cody 1971 and Ritchie 2003). It is possible that the outbreeding ancestral morphotype of *Cypripedium passerinum* is a Beringian relict. In Beringian habitats that have existed for hundreds of thousands of years, and presumably include pollinators, cross-pollination was likely advantageous. *Cypripedium passerinum* presently occurs in *Alnus crispa* or *Betula glandulosa* shrubland habitats that are believed to have existed in Beringia during full glacial times (e.g., Hopkins 1982; Ritchie and Cwynar 1982; Cwynar 1990; Cwynar and Spear 1991; Lacourse and Gajewski 2000) when the rest of Canada was covered by ice up to a few km deep. *Cypripedium passerinum* also occurs in open aspen (*Populus*) and spruce (*Picea*) woodland. Both of these species evidently existed in isolated valley-bottom habitats within the Beringian steppe plateaus, although *Populus* pollen does not preserve well making its widespread but isolated occurrences more difficult to detect (Zazula et al. 2006; Zazula, personal communication). *Cypripedium passerinum* also occurs in parts of the north, to 68°N, where Beringian species are predominant. As it spread from Beringia across the rest of northern Canada into new, recently deglaciated territory, there

was likely a strong selection for self-pollination, this explaining the apparent predominance of self-pollinating morphotypes.

Twenty-Four-Hour Activity Budgets of Mule Deer, *Odocoileus hemionus*, in the Aspen Parkland of Eastcentral Alberta

GERALD W. KUZYK[1,2] and ROBERT J. HUDSON[1]

[1]Department of Renewable Resources, University of Alberta, Edmonton, Alberta T6G 2H1 Canada
[2]Present address: Ministry of Environment, Wildlife Science Section, P.O. Box 9338, Victoria, British Columbia V8W 9M1 Canada; e-mail: Gerald.Kuzyk@gov.bc.ca

Kuzyk, Gerald W., and Robert J. Hudson. 2007. Twenty-four-hour activity budgets of Mule Deer, *Odocoileus hemionus*, in the aspen parkland of eastcentral Alberta. Canadian Field-Naturalist 121(3): 299-302.

We documented seven 24-h activity budgets of two adult Mule Deer (*Odocoileus hemionus*) does without fawns in the Aspen Parkland of Alberta when the vegetation was green (June, July), maturing (September) and cured (October). They spent about 40% (mean = 42.3%) of each day foraging, somewhat more when vegetation was green (40-47%) and maturing (45%), and less time in October, when the vegetation was cured (38-39%). The percentage of time Mule Deer were bedded each day generally equaled or slightly exceeded (33-53%) that of foraging. Walking was a prevalent activity (3-24%), especially in autumn and little time was invested in other activities such as social interactions and grooming (1-4%). There were generally more feeding bouts (10-16/day) than bedding bouts (4-10/day) per day, and feeding bouts were shorter (37-68 minutes) than bedding bouts (69-133 minutes). Mule Deer displayed polycyclic feeding cycles with slight increases in feeding activity near dawn and dusk.

Key Words: Mule Deer, *Odocoileus hemionus*, activity, foraging, Alberta.

Mule Deer (*Odocoileus hemionus*) range over much of western North America, yet little is known about their foraging ecology on northern ranges (Kuzyk 2008), especially regarding their daily activities. Documenting how much time Mule Deer spend feeding during different stages of vegetation phenology provides insight into behavioral adaptations in seasonal northern environments. Browsing ruminants normally spend about 50% each day foraging, with feeding times varying with forage phenology, morphological and physiological characteristics such as mouth shape, gut capacity and food passage rate (du Toit and Yetman 2005). Activity budgets can be used to quantify daily foraging times and other major activities. One difficulty in conducting activity budgets is remaining close enough to a focal animal to accurately quantify activity patterns, especially during darkness. Using tame deer is one way to maintain consistent visual contact with a focal animal for a 24-h period (Collins and Urness 1983) and provides reliable results, as food intake in tame deer is deemed innate (Spalinger et al. 1997). Maintaining visual contact with tame deer also allows daily feeding cycles and duration of feeding bouts to be quantified.

The purpose of this study was to quantify activity budgets of Mule Deer on northern ranges when the vegetation was green (June and July), maturing (September) and cured (October). From allometric considerations (Mysterud 1998; du Toit and Yetman 2005), we predicted that Mule Deer would spend 50% of their daily activity budget foraging and foraging time would change with forage phenology. We predicted that Mule Deer would spend least time foraging in summer when vegetation was green and the most time in autumn when the vegetation had cured because required selectivity increases search time.

Methods

Our study animals were two unbred adult Mule Deer does which were hand-reared as fawns. The animals were four and six years old and weighed 59 and 60 kg, respectively, at the beginning of the study. These animals would allow researchers to remain within five meters of them, apparently without disturbing their normal activities. The deer were released into 3-7 hectare fenced enclosures (2.2 m high) in an Aspen Parkland habitat (Strong 1992) at the University of Alberta Ranch (53°N, 111°31'W) approximately 150 kilometers southeast of Edmonton, Alberta. Each deer was instrumented with a radiocollar (Telonics TGW-3570) and placed in a paddock with two other Mule Deer as part of a larger study (Kuzyk 2008). This study was approved by the University of Alberta Faculty Animal Policy and Welfare Committee (Protocol HUDS 2004–33B), following guidelines of the Canadian Council on Animal Care.

Scan sampling (Altmann 1974) was conducted on focal deer throughout one complete 24-h period and repeated seven times during the summer and autumn of 2004 and 2005 (Table 1). One Mule Deer (501H) was used for six of the sampling periods and was substituted for another Mule Deer (515K) to compare behaviors at the same season but different years (Table 1). Only one 24-h activity budget was conducted per sampling period. The activity budget was classed into predominant activities and recorded every 10 minutes (Collins and Urness 1983). One observer closely followed

the deer and used a stopwatch to time predominant activities within a 10-minute bout. An activity had to occur for 5 minutes or longer within a 10-minute time interval to be classed as predominant. Predominant activities were feeding, bedding, walking and other (social interactions, grooming). Feeding was defined as ingesting, chewing or intently searching (smelling plants) for food, while walking was defined as a deer moving without biting vegetation. Ruminating was associated with bedding. Each observer spent between 6 and 10 hours with the Mule Deer and overlapped shifts by approximately 15 minutes to minimize disturbance to the deer. At night, a flashlight was used to monitor the Mule Deer by concentrating the light beam on the posterior portion of the body to minimize disturbance.

Daily patterns of feeding and bedding were determined by the number and duration of bouts that were separated by at least 10 minutes (Pépin et al. 2006). Daily feeding cycles were evaluated by the proportion of time spent feeding each hour over a 24-hr period. The proportion of time spent feeding at dawn and dusk was determined by the mean amount of time spent feeding 1-3 hours before, 1 hour before and 1 hour after and 1-3 hours after sunrise and sunset (Colman et al. 2001). Descriptive analyses of activities are presented due to insufficient sample sizes for statistical comparisons.

Results

Mule Deer spent about 40% of each day foraging with slight increases when the vegetation was green and maturing (40-47%) and less time when the vegetation was cured (38-39%). Mule Deer spent between 33-53% of each day bedded (Table 1). Feeding bouts were generally shorter (37-68 min) than bedding bouts (69-133 min) and there were more feeding bouts (10-16/day) than bedding bouts (4-10/day) per day (Table 2). Feeding cycles were polycyclic (Figure 1) with increased feeding activity near sunrise and sunset (Figure 2).

Discussion

Our research documented and compared daily foraging activities of Mule Deer on a northern range when the vegetation was at three phenological states, and deer were at successive stages of their annual growth cycle. Our findings did not meet our prediction that Mule Deer would spend less time foraging in summer than in autumn. We assumed abundant forage quantity and quality would account for reduced foraging activity in summer, but early summer is the period when weight gain and appetite are greatest, despite the absence of milk production for fawns. Possibly Mule Deer were being very selective in forage quality in the summer period and spent more time consuming the

easily digestible forbs when they were readily available. In September, Mule Deer may have increased foraging times as the vegetation started to senesce and deer spent more time searching for green vegetation, especially forbs beneath the grass layer.

Mule Deer spent the least time foraging in October when the vegetation had cured. This may be due to Mule Deer adjusting their bite sizes (Kuzyk and Hudson 2006) to compensate for the lack of green vegetation. Mule Deer on northern ranges have high consumption rates (g/min) in October and can forage at rates that are near theoretical maximum by feeding on Canadian thistle (*Cirsium arvense*) (Kuzyk and Hudson 2006). Increased bite sizes in October could lead to a quicker gut fill compared to other seasons.

The percentage of time Mule Deer bedded each day equaled or exceeded that of the time spent foraging. High diurnal temperatures can reduce Mule Deer activity (Hayes and Krausman 1993), especially during midday (Ager et al. 2003), and could account for the difference. Beir and McCullough (1990) found that White-tailed Deer (*Odocoileus virginianus*) were relatively inactive in summer when feeding on abundant forage. Long bedding bouts may reflect requirements for rumination of coarse forage.

There was variation in behaviors between the two Mule Deer in October in different years. Time spent foraging was almost identical, whereas the time spent bedding contrasted greatly as the individual used in multiple trials (501H) spent 36.7% of the day bedding compared to 52.9% for the other individual (515K). Also, 501H spent substantially more time walking (24%) than did 515K (7%), which may be due to individual variations in behaviors.

Mule Deer had polycyclic feeding cycles which has been determined for some other northern ungulates (Colman et al. 2001). The cycles may be driven by rumen fill and time required for digestion (Pérez-Barbería and Gordon 1999), as these Mule Deer experienced little disturbance and few intra-specific interactions (Kuzyk and Hudson 2007). Mule Deer increased feeding activity near sunrise and sunset which is similar to the behavior of White-tailed Deer (Beir and McCullough 1990), as crepuscular activity is a common behavior for small ruminants to reduce predation risk (Pérez-Barbería and Gordon 1999). There appeared to be a more pronounced feeding peak at sunrise, possibly due to rapid daytime heating in summer and fall or increased insect harassment. Additional studies quantifying activity budgets of Mule Deer would help clarify determining factors of daily feeding cycles.

Acknowledgments

This study was supported by a strategic research grant through the Natural Sciences and Engineering Research Council of Canada and a University of Alberta Graduate Research Assistantship. We appreciate the field assistance of P. DeWitt, K. Kuzyk, A. Lockwood, N. Maleki, and S. Vinge and thank B. Irving and staff at the University of Alberta Ranch (Kinsella) for animal handling.

Patterson, Jesse E. H., Stephen J. Patterson, and Jay R. Malcolm. 2007. Cavity nest materials of Northern Flying Squirrels, *Glaucomys sabrinus*, and North American Red Squirrels, *Tamiasciurus hudsonicus*, in a secondary hardwood forest of southern Ontario. Canadian Field-Naturalist 121(3): 303-307.

Through deployment of artificial nest boxes, we examined the composition of cavity nest materials used by Northern Flying Squirrels (*Glaucomys sabrinus*) and North American Red Squirrels (*Tamiasciurus hudsonicus*) in a secondary hardwood forest of southern Ontario, Canada. We collected 32 nests of known species association and found that 85.7% of *G. sabrinus* nests and 77.8% of *T. hudsonicus* nests were constructed almost entirely of shredded bark from Eastern White Cedar (*Thuja occidentalis*). Mean nest depth across all samples was 12.2 cm and showed no significant difference between species or between spring and summer nests. We review the antiparasitic properties of *T. occidentalis* and suggest that the use of shredded cedar bark by *G. sabrinus* and *T. hudsonicus* to line nest cavities may be a behavioural adaptation, which reduces ectoparasite loads in the nest environment.

Key Words: Northern Flying Squirrel, *Glaucomys sabrinus*, North American Red Squirrel, *Tamiasciurus hudsonicus*, ectoparasites, nest box, nest material, nest-protection hypothesis, thermoregulation, Eastern White Cedar, *Thuja occidentalis*, Ontario.

Tree cavities are a critical resource for many tree squirrels in forest ecosystems, providing sites for raising young, avoiding predators, and improving thermoregulation (Collias 1964; Weigl 1978; Wiebe 2001). Tree cavities are generally most abundant in old growth forests where large diameter trees and well-decayed snags are commonplace (Holloway and Malcolm 2006; Holloway and Malcolm 2007). Cavities also may form in live trees where the entry of rot has been facilitated by disease, deformities, broken limbs or woodpecker excavations. Where tree cavities are not readily available, many tree squirrels use external nests (dreys) or subterranean nests, although evidence is emerging that tree cavities are preferentially selected when available (Bakker and Hastings 2002). Nest materials used in cavity nest construction may not only act to increase ambient temperature in the nest environment and provide comfort for nest occupants, but may also reduce ectoparasite loads and repel moisture in these dark, damp microclimates (Stapp et al. 1991; Hemmes et al. 2002.) However, despite their importance, tree cavities and cavity nests are rarely incorporated into studies of tree squirrels (Fokidis and Risch 2005).

The nocturnal Northern Flying Squirrel (*Glaucomys sabrinus*) and the diurnal North American Red Squirrel (*Tamiasciurus hudsonicus*) are both occasional cavity nesting, arboreal rodents common in temperate and boreal forests of North America. Both species are primarily associated with conifer-dominated forests, although in many areas of eastern North America they inhabit hardwood and mixed hardwood-conifer forests (Flyger and Gates 1982; Holloway and Malcolm 2006; Patterson 2008). Both *G. sabrinus* and *T. hudsonicus* have been found to use cavities in trees more intensively than external or subterranean shelters, especially for natal nests (Layne 1954; Bakker and Hastings 2002; Holloway and Malcolm 2007).

Nest materials used by arboreal squirrels have been found to vary geographically (Muul 1974). However, most reports describing nest materials employed by squirrels have been qualitative in nature and have focused on dreys. *Tamiasciurus hudsonicus* dreys have been noted to include grape bark, deciduous leaves, dried grasses, moss, feathers, fur and soft inner bark (Layne 1954). Similarly, dreys of *G. sabrinus* have been found to consist of dried grasses, shredded bark, mosses, twigs and lichens (Rust 1946; Mowrey and Zasada 1984). Cavity nests have been described quantitatively only once for *G. sabrinus* (Hayward and Rosentreter 1994). Using nest boxes, these authors found that *G. sabrinus* in the northern Rocky Mountains of central Idaho and western Montana primarily constructed cavity nests from arboreal lichens, especially of the genera *Bryoria* and *Letharia*. We are not aware of studies that have quantified cavity nest materials of *T. hudsonicus*; however, Hayward and Rosentreter (1994) suggest a preference for grasses and shredded bark. Published data on *G. sabrinus* and *T. hudsonicus* nest materials, and associated seasonal differences and depths, in the Great Lakes-St. Lawrence forest region of eastern North America do not exist. In general, the study of nest material use and function in mammals has

received very little attention by researchers and thus warrants investigation.

In order to gain a more complete understanding of the habitat requirements for *G. sabrinus* and *T. hudsonicus* in northern secondary hardwood forests, we characterize cavity nest materials used by these two species in a large network of nest boxes in southern Ontario, Canada. We hypothesized that *G. sabrinus* and *T. hudsonicus* would preferentially select nest materials that favoured cavity nest occupation (i.e., parasite reduction, moisture repellency). Nest depth measurements were investigated as a function of the type of nest material and season (spring and summer); we also assessed seasonal variation in nest material composition. We predicted that nest depths would exhibit interseasonal variability if nest construction was primarily to enhance thermoregulation, such that deeper nests would be constructed under colder temperature regimes. Given the prevalence of shredded cedar bark in the nests of both *G. sabrinus* and *T. hudsonicus,* we discuss the potential antiparasitic and thermoregulatory benefits of Eastern White Cedar (*Thuja occidentalis*) bark.

Study Area

The study was conducted in Bruce and Grey counties, Ontario, Canada (43°59' to 45°12'N, 80°22' to 81°39'W), which together encompass an area of about 22 000 km^2. Nest boxes were placed in trees growing at various elevations, ranging from approximately 200 m to 450 m above sea level. Approximately 22% of the landscape is currently composed of closed-canopy secondary forests, which are dominated by Sugar Maple (*Acer saccharum*), White Ash (*Fraxinus americana*) and American Beech (*Fagus grandifolia*). Other common tree species include Eastern White Cedar, Eastern Hemlock (*Tsuga canadensis*), aspen (*Populus tremuloides, P. grandidentata*) and White Birch (*Betula papyrifera*) (Patterson 2008). Small stands of Eastern White Pine (*Pinus strobus*) and spruce (*Picea glauca, P. mariana, P. rubens*) occur throughout the area, often in plantations.

Materials and Methods

A total of 266 nest boxes were installed between 2002 and 2004 as part of a larger study being conducted by SJP on *G. sabrinus*. Sampling effort varied among years due to logistical constraints. In 2002, 154 boxes were installed; an additional 36 boxes were installed in 2003 and the final 76 boxes were installed in 2004. All nest boxes were placed at heights of 3-4.5 m on trees that had a diameter at breast height >17 cm. Following Carey (2002), nest boxes were established at a density of three nest boxes/ha to allow for a balance between occupancy rates and monitoring effort. Three or more boxes were placed at each of 70 sites across the study region.

Boxes were constructed following Sonenshine et al. (1973), except for the door which was top mounted and could be flipped up to remove any animals and nest material. Our entrance hole was also of larger diameter (4 cm) to permit use by *G. sabrinus* and *T. hudsonicus,* but exclude Eastern Grey Squirrels (*Sciurus carolinensis*). All boxes were mounted to the tree trunk and any tree branches were removed from below the nest box.

All boxes were intensively checked twice per year during the day: once in the spring and once again in autumn. Spring checks were conducted between 12 May and 12 June following the onset of parturition, whereas autumn checks were conducted between 12 October and 12 November. Cursory visual nest box inspections were conducted monthly to monitor the condition of the boxes, but no sampling was done on these occasions. These visual inspections indicated that neither *G. sabrinus* nor *T. hudsonicus* used the nest boxes in late autumn and winter (early December – late February), presumably because individuals abandoned the nest boxes for larger, better insulated natural cavities or subnivean nests. Therefore, nests found at the spring inspection had been constructed between early March and the date of inspection in spring (hereafter termed "spring" nests), whereas those found at the autumn inspection had been constructed between the spring and autumn inspection dates (hereafter termed "summer" nests). Where nests were present and occupied at time of inspection, we recorded the location, number and reproductive condition of occupants and nest depth. Samples of nest material were collected from all nests for identification of materials. In cases where the nest box was not occupied at the time of inspection, the entire nest was removed. In cases where the nest box was occupied at the time of inspection (14% of the nests), a small sample of nest material was initially removed and the entire nest was subsequently removed during targeted monthly nest box examinations following the departure of nest occupants. We removed nest material not only to examine nest materials, but also because Hayward and Rosentreter (1994) observed that nest boxes were typically not occupied in successive years if used nest material was present. Nest depth was always determined during the initial investigation and measured *in situ* along the vertical dimension from the internal base of the nest box to the top of the nest. Nest volume was determined by multiplying the nest depth by the internal width and length dimensions of the nest box.

Results

Nest Box Occupation

Between 2002 and 2005, we found 224 occupied and unoccupied nests. Of these, 32 were occupied when checked (14 *G. sabrinus* and 18 *T. hudsonicus*). Females were found occupying the nest boxes in 12 cases for *G. sabrinus* and 14 cases for *T. hudsonicus*. Lone males were occasionally found occupying the nest boxes (two *G. sabrinus* and four *T. hudsonicus*).

Nest Materials of *G. sabrinus* and *T. hudsonicus*

Twelve of the 14 boxes occupied by *G. sabrinus* and 14 of the 18 boxes occupied by *T. hudsonicus* contained >90% shredded cedar bark by volume. One *G. sabrinus* nest was composed entirely of fibreglass insulation and another was composed of >80% shredded deciduous bark. Trace amounts of peat moss, dried grasses, cedar leaves and twigs also were found in occupied *G. sabrinus* nests. Two *T. hudsonicus* nests were composed entirely of dried grasses and two nests contained >80% deciduous leaves. Trace amounts of shredded plastic, bird feathers, animal fur, dried grasses and deciduous leaves also were found in occupied *T. hudsonicus* nests.

Nest materials did not appear to differ between seasons ($t = -1.892$, $P = 0.06$), with shredded cedar bark appearing as the most prominent nest material in both spring (84.5%) and summer (79.3%). Small sample sizes for male nests did not allow for robust comparisons between male and female nest materials.

Nest Depth

Mean depth of nests occupied by *G. sabrinus* was 12.1 cm (SD = 2.4, range = 6.7 to 15.3 cm) and for *T. hudsonicus* was 12.3 cm (SD = 2.1, range = 9.1 to 17.8 cm), although the difference was not statistically different ($t = 0.31$, $P = 0.76$). We found no statistical difference between spring (*G. sabrinus* mean = 11.9 cm; *T. hudsonicus* mean = 12.6 cm) and summer (*G. sabrinus* mean = 11.1 cm; *T. hudsonicus* mean = 12.7 cm) nest depths for either species for occupied nests (*G. sabrinus*: $t = 0.55$, $P = 0.30$; *T. hudsonicus*: $t = 0.17$, $P = 0.43$). Small sample sizes for male nests did not allow for robust comparisons between male and female nest depths.

Discussion

The prominence of cedar bark in *G. sabrinus* and *T. hudsonicus* nests may be explained by at least two, nonmutually exclusive, hypotheses: nest-protection and thermoregulation. The nest-protection hypothesis has received much attention from ornithologists to explain the use of green vegetation in avian nests. Initially suggested by Wimberger (1984) and tested by Clark and Mason (1985), the nest-protection hypothesis posits that animals exploit the antiparasitic properties of certain plant species that emit specific volatile compounds (Dawson 2004). All plants contain secondary metabolites that are used as a defense against disease and herbivory (Clark and Mason 1988) and, when these plants are used as nesting materials, certain compounds may reduce ectoparasite loads in the nest environment. Numerous studies have supported the nest-protection hypothesis in birds (Wimberger 1984; Rodgers et al. 1988; Fauth et al. 1991; Lafuma et al. 2001). The nest protection hypothesis has found support on at least one occasion for small mammals: Hemmes et al. (2002) reported that Dusky-footed Wood Rats (*Neotoma fuscipes*) placed California Bay (*Umbellularia californica*) leaves around their nest sites. Laboratory tests revealed that when incubated with torn *U. californica* leaves for 72 h, survival of flea larvae was reduced by 74% compared to controls. By using shredded Eastern White Cedar bark as a primary nest material, *G. sabrinus* and *T. hudsonicus* also may be limiting exposure to nest-borne ectoparasites. Phytochemical analysis of *T. occidentalis* bark has revealed 22 volatile compounds, including monoterpenes, fenchene, camphene, camphor, carvacol and paracymene (Shaw 1953; Witte et al. 1983; Yatagai et al. 1985; Keita et al. 2001), several of which have noted antiparasitic or insecticidal properties (Adams et al. 1988; Adams 1993; Keita et al. 2001).

Support for the nest protection hypothesis is bolstered by the use of lichens in nests of *G. sabrinus* found in western North America. Antiparasitic effects have been described for several species of lichen. Hayward and Rosentreter (1994) found that *G. sabrinus* selected lichens containing the secondary compounds norstictic acid, fumarprotocetraric acid, vulpinic acid and atranorin, all of which have been attributed with varying degrees of antiparasitic or antimicrobial effects (Giez et al. 1994; Tay et al. 2004; Yilmaz et al. 2004). These various studies support the possibility that the use of *T. occidentalis*, as well as several lichen species, by *G. sabrinus* and *T. hudsonicus* may be a behavioural adaptation for ectoparasite control in the nest environment. Further testing of the antiparasitic effects of *T. occidentalis* volatile oils and secondary compounds on known *G. sabrinus* and *T. hudsonicus* ectoparasites is required.

An alternative hypothesis is that shredded cedar bark may offer greater insulative properties than other available materials. Hayward and Rosentreter (1994) suggested the same hypothesis when characterizing the primary use of lichens as nest material by *G. sabrinus*. This hypothesis is based on the finding by Stapp et al. (1991) that nests composed of plant fibres allowed Southern Flying Squirrels (*Glaucomys volans*) to reduce their energy expenditure when experimentally subjected to cold temperatures. We are not aware of studies on the thermal properties of cedar bark, lichens or other nest materials found in this study. A common assumption is that nest materials with greater thermal properties are favoured, and/or that nest depth would peak, during colder periods. Contrastingly, we found that shredded cedar bark was used equally in spring and summer and that nest depth did not vary between the two seasons. This suggests that cedar bark may not be chosen solely for thermoregulatory purposes; however, we are unable to reject the thermoregulation hypothesis outright without further empirical testing.

We dismiss a third potential hypothesis that squirrels choose the most widely and readily available materials for use as nest substrate. Patterson (2008) found that deciduous trees accounted for approximately 80% of the tree composition in our study area by basal area,

while Eastern White Cedar accounted for less than 10% of the total forest composition on average, by basal area. Deciduous leaves and deciduous tree bark are therefore more greatly available than *T. occidentalis* bark in our study area. At some sites where cedar bark nest material was found to occur, Eastern White Cedar trees accounted for only 2% or less of the total tree composition (Patterson 2008). On one occasion during this study we observed a single female *G. sabrinus* travel over 500 m to the nearest *T. occidentalis* tree to acquire cedar bark for nest construction. Mosses, lichens, and grasses are also widely available throughout the study area (J. Patterson, unpublished data) and yet were rarely found as nest materials in this study.

Acknowledgments

We thank the Grey Sauble Conservation Authority, the Saugeen Valley Conservation Authority and the various private landowners who graciously made their land available for this study. We also would like to thank Thistlewood Timber Frame Homes in Markdale, Ontario, for generously donating the lumber used for the nest boxes. J. Bowman, D. Nagorsen and two anonymous reviewers provided helpful suggestions for the improvement of this manuscript. We appreciate the support and field assistance provided by H. Maddin and M. Patterson. This project was funded, in part, by the Natural Sciences and Engineering Research Council of Canada Undergraduate Student Research Award to JEHP.

Reed, John A., Deborah L. Lacroix, and Paul L. Flint. 2007. Depredation of Common Eider, *Somateria mollissima*, nests on a central Beaufort Sea barrier island: a case where no one wins. Canadian Field-Naturalist 121(3): 308-312.

Along the central Beaufort Sea, Pacific Common Eiders (*Somateria mollissima v-nigra*) nest on unvegetated, barrier islands; often near nesting Glaucous Gulls (*Larus hyperboreus*). Nest-site choice likely reflects a strategy of predator avoidance: nesting on islands to avoid mammalian predators and near territorial gulls to avoid other avian predators. We observed a nesting colony of Common Eiders from first nest initiation through nesting termination on Egg Island near Prudhoe Bay, Alaska (2002 – 2003). Resident gulls depredated many eider nests, mostly during initiation. All nests failed when an Arctic Fox (*Alopex lagopus*) visited the island and flushed hens from their nests, exposing the eggs to depredation by the fox and gulls (resident and non-resident). Common Eiders actively defended nests from gulls, but not from foxes. Likely all three species (i.e., eiders, gulls, and foxes) ultimately achieved negligible benefit from their nest-site selection or predatory activity: (a) island nesting provided no safety from mammalian predators for eiders or gulls, (b) for Common Eiders, nesting near gulls increased egg loss, (c) for Glaucous Gulls, nesting near colonial eiders may have reduced nest success by attracting the fox, and (d) for Arctic Foxes, the depredation was of questionable value, as most eggs were cached and probably not recoverable (due to damage from fall storms). Thus, the predator-prey interactions we observed appear to be a case where little or no fitness advantage was realized by any of the species involved.

Key Words: Arctic Fox, *Alopex lagopus*, Common Eider, *Somateria mollissima*, Glaucous Gull, *Larus hyperboreus*, nest depredation, predator-prey interaction, Beaufort Sea, Alaska.

Along the central Beaufort Sea, nest success of Pacific Common Eiders (*Somateria mollissima v-nigra*) is highly variable, with egg depredation by Glaucous Gulls (*Larus hyperboreus*) and Arctic Foxes (*Alopex lagopus*) being the primary cause of nest failure (Johnson and Herter 1989; Johnson 2000). Common Eider nest-site choice on coastal barrier islands is thought to reflect a strategy of predation avoidance. Typically, Common Eiders nest in colonies, often within the territory of nesting gulls (Noel et al. 2005). By nesting on islands, Common Eiders may avoid mammalian predators such as foxes (Johnson 2000; Noel et al. 2005). By nesting near gulls, eiders may benefit from territorial defense by gulls (Bourget 1973; Schamel 1977; Götmark and Åhlund 1988; Fournier and Hines 2001), but may incur additional risk if the resident gulls depredate their nests. If the depredation rate exceeds the gulls' protective benefit, then Common Eiders could be experiencing an unsustainable situation similar to the "ecological trap" described by Dwernychuk and Boag (1972).

As part of a larger study of Common Eider breeding ecology, we conducted an intensive observational study of nesting biology on Egg Island, near Prudhoe Bay, Alaska. Our primary objective was to replicate the study by Schamel (1974, 1977) and document the behavioral interactions among Common Eiders and nest predators with minimal researcher disturbance.

Methods

We selected Egg Island for this study because data from annual surveys showed relatively consistent concentrations of Common Eider nests (Noel et al. 2005) and a similar observational study of Common Eider reproduction had been conducted there in the 1970s (Schamel 1974, 1977). Egg Island is a small unvegetated island that is part of the chain of barrier islands that form Simpson Lagoon (Noel et al. 2005). Prior to Common Eider nest initiation in 2002 and 2003, we erected elevated observation blinds near the main colony. In 2002, we used two blinds with 30 m above-ground plywood access tunnels, and in 2003 we used one blind with a 25 m access tunnel. The blinds were 1.2 m × 1.2 m × 1.5 m plywood boxes raised 2.5 m above the ground. Observers accessed the island in small boats, using the tunnels to hide our approach. Boating was limited to a single landing and departure per day and there was no observer activity on Egg Island outside of the tunnels and blinds. Common Eiders were never observed to flush while we accessed the blinds. However, the entrance of one tunnel in 2002 was near three Glaucous Gull nests. These gulls often flushed as we approached, but remained near their nest-site and returned to the nest quickly after we entered the blind.

With few exceptions due to poor weather, we recorded daily nest observations during blocks of 4-6 × 1 h

observation sessions. We staggered our observation blocks to cover the entire 24-hour period, because, at the latitude of our study site, the sun does not set during the entire nesting period. We conducted observations from initiation of the first eider nest until incubation at all nests terminated each year. During observation sessions, we mapped all nests within view of the blinds and recorded the amount of time each nest was occupied. We recorded all interactions with predators and, each hour, we performed 15 min predator watches during which we counted all aerial and ground patrols by avian predators. We tallied these counts to create an index of avian predation pressure.

We considered a nest to be a site in which at least one egg was seen or a site that was occupied by a hen during observations for > 24 h. We considered incubation to have begun when a hen was seen on a nest full-time after at least three consecutive days of attendance. Nests were deemed failed when no eider was seen using the site on two consecutive days. Nests occupied > 24 h after an observed depredation event were counted as partial depredation, whereas nests abandoned shortly after depredation were considered to be completely depredated (i.e., entire clutch loss). To estimate inter-nest distances, we visited each nest site after all nesting birds left the island and recorded coordinates with a GPS unit. All means are provided ± SE.

Results

We conducted 126 h of observations on 16 days (15 June – 3 July) in 2002, and 140.5 h of observation on 23 days (19 June – 13 July) in 2003. We observed 45 Common Eider and 10 Glaucous Gull nests in 2002, and 37 Common Eider and 9 Glaucous Gull nests in 2003. Gull nest initiation preceded eider nest initiation by several days. The majority of Glaucous Gull nests were already in the incubation stage when observations began each year, whereas the median initiation dates for Common Eiders were 23 June and 25 June, in 2002 and 2003, respectively. In both years, eider and gull nesting periods were terminated prior to hatch when a single Arctic Fox accessed the island and destroyed all nests during the incubation stage.

Gull Predation

We conducted 328 avian predator patrol watches. Glaucous Gulls were the most common predator; other avian predators (jaegers, *Stercorarius* spp., and Ravens, *Corvus corax*) were seen on only seven occasions. The search rate by gulls appeared similar each year ($\bar{x}_{\text{patrols/h}} = 17.2 \pm 1.6$ in 2002, and 14.1 ± 1.0 in 2003), but the search technique changed between years. In 2002, 68.2% ± 3.0 of patrols were aerial, while in 2003 aerial patrols accounted for only 32.9% ± 2.7 of the total. Concurrently, the mean distance between eider nests and the nearest Glaucous Gull nest decreased significantly ($t_{67} = 3.58$, $P < 0.001$) from 75.8 m ± 4.3 in 2002 to 35.2 m ± 9.2 in 2003. This shift in Glaucous Gull patrols may reflect variation in the distance between Common Eider and Glaucous Gull nests between years.

Prior to the fox arrival in 2002, 42% (19 of 45) of attempted Common Eider nests had failed and, in 2003, 70% (26 of 37) had failed but the observation period lasted 10 days longer in 2003. The daily failure rates of 1.2 nests/day in 2002 and 1.3 nests/day in 2003 were similar. Glaucous Gull depredation was the likely cause of all of these failed nests. We directly observed Glaucous Gull depredation in 7 and 11 cases, in 2002 and 2003, respectively. Most nests were lost during the egg laying stage; however, some nests were also destroyed during incubation (4 in 2002, 10 in 2003). Proximity to gull nests appears to have been important in nest failure. Fifty percent and 75% of Common Eider nests < 30 m from gull nests failed in 2002 and 2003, respectively. In 2003, more nests ($n = 20$) were within 30 m of gull nests than in 2002 ($n = 4$). From the blinds, we were unable to see into nests, and thus could not quantify clutch size or proportional egg loss. Yet, in 2003 we did see 38 individual eider eggs eaten by gulls; of these, 14 were taken by Glaucous Gulls known to be nesting in the midst of the Common Eider colony (10 eggs were taken by a single pair of nesting Glaucous Gulls).

Partial predation was uncommon, as Glaucous Gulls typically removed all eggs once they gained access to a nest. We observed six cases of partial predation (4 Common Eider eggs, 2 Glaucous Gull eggs) across years. In one case, a Glaucous Gull pressured a pair of Common Eiders for 41 min before finally stealing an egg from beneath the hen. During this encounter, the hen never moved from the nest and did not indicate awareness of the egg loss. The attending drake actively attempted to defend the nest. In another instance, a Glaucous Gull pulled nest material from under an incubating hen, but was unable to remove any eggs. We never observed a Glaucous Gull displace a Common Eider from a nest.

Common Eiders took attendance breaks throughout the nesting period, averaging 8.2 ± 1.3 min/break based on 57 breaks of known length. Across years, Glaucous Gulls attempted to depredate nests during nearly one quarter (i.e., 21) of the 86 observed attendance breaks, and were successful in half of their attempts (11 of 21). Regularly, we observed Glaucous Gulls standing within 1 m of occupied Common Eider nests. On five of these occasions the incubating hens left their nests unattended; only two returned to successfully defend their nest.

Common Eiders showed three defense strategies against Glaucous Gulls in this study: (1) passively ignoring harassment and sitting tight on nests, (2) actively nipping/lunging at nearby gulls from occupied nests (35% of active behaviors), and (3) actively chasing gulls from their nest after leaving it unoccupied for an

attendance break (65% of active behaviors). The male Common Eider nest defense described earlier was not a singular event; rather, while attending females at nest sites, males often played an active role in defense. Male attendance of females during nest prospecting and initiation was high (for the three days prior to peak initiation in 2002 and 2003, 24% and 71% of active nests were attended by males) then tapered through early incubation. Across years, males were involved in 13 of 15 observed nest defense events prior to 29 June and 0 of 8 defenses thereafter.

Fox Predation

In both years, a single Arctic Fox gained access to Egg Island during the incubation period. On 3 July 2002 it arrived and departed across ice floes and on 13 July 2003 it swam at least one km to Egg Island from a nearby island and left by swimming toward the mainland (> 2 km away). In both cases, the fox was responsible (directly or indirectly) for the destruction of all nests that were active at the time of arrival. The entire fox visit to Egg Island was observed in 2002 (duration = 3 h 11 min) but not in 2003. When observers arrived in 2003 (after a 37 h absence due to weather conditions) the fox was still on the island, but all nests had been destroyed. There were 32 active nests (26 Common Eider, 6 Glaucous Gull) on the island when the fox arrived in 2002, and in 2003 there were 18 active nests (11 Common Eider, 7 Glaucous Gull) during the last observation prior to the fox visit.

When the fox arrived in 2002, there were approximately 30 non-resident Glaucous Gulls loafing on Egg Island in addition to the resident Glaucous Gulls from the six active nests. During observations in 2002, Glaucous Gulls with nearby nests attacked the fox, whereas the other gulls searched through the unprotected nests (both eider and gull) and ate the contents of all eggs encountered. Some gulls ate egg contents at the nests, but others carried eggs up to 20 m away before consuming them.

The fox observed in 2002 cached the vast majority of eggs that it encountered, eating only one gull egg, one eider egg, and the contents of a Snow Bunting (*Plectrophenax nivalis*) nest. It cached at least 34 eider and 4 gull eggs, taking on average 2.3 min to find an egg, cache it, and find another egg. Eggs were carried 20-100 m from the nest and buried 2-5 cm deep in areas of open sand or gravel. We do not have clutch size data from Egg Island; however, the mean Common Eider clutch size from neighboring islands in 2002 was 2.6 eggs/nest. Given this estimate, the fox took approximately 56% of the Common Eider eggs on the island, while the remaining eggs were eaten by Glaucous Gulls.

Resident Glaucous Gulls actively attacked and harassed the fox, but the fox was never seen to leave a site or egg as a result of an attack. Common Eiders never defended their nests from the fox; rather, they flushed from their nest when the fox approached to within 20 m.

Discussion

None of the three species observed in this study appeared to have gained fitness from the use of Egg Island or from interactions on the island. In fact, it appears that they all may have fallen into a situation similar to an "ecological trap". That is, each was enticed by initial conditions (or expectation of conditions) which could have confered a fitness benefit, but due to changes in those conditions, the final result was the loss of fitness.

Glaucous Gulls nested earlier than Common Eiders and may have chosen nest sites on Egg Island in anticipation of Common Eider nests as a potential source of prey or in an attempt to avoid mammalian predators. Regardless, Common Eiders, ultimately, established their nests near existing Glaucous Gull nests. Our results suggest that proximity to Glaucous Gull nests increased avian depredation risk for Common Eiders. Similar to the results of Schamel (1977), the majority (71%) of eider nests were depredated when located within 30 m of gull nests.

On the barrier islands of the central Beaufort Sea there is little vegetation, and the sparse driftwood provides minimal concealment for incubating birds (Noel et al. 2005). Female Common Eiders taking incubation breaks seem to be obvious to nearby gulls, as one-third of our observations of a Glaucous Gull predation event were apparently cued by the eider leaving for an incubation break. Although Common Eider incubation breaks were generally short and probably infrequent (Bolduc and Guillemette 2003; Swennen et al. 1993), our observations indicate that the detection of any break by a Glaucous Gull could lead to the loss of an entire clutch. Female Common Eiders generally fast through the entire nesting period (Korschgen 1977; Bolduc and Guillemette 2003; Swennen et al. 1993), but several authors have noted the physiological importance of drinking periodically throughout incubation (Bolduc and Guillemette 2003; Criscuolo et al. 2000). Thus, it appears that eider hens were forced to trade current reproductive effort for survival and future reproductive potential. It is notable that attending male Common Eiders probably did not increase nest detection substantially, as Common Eider hens were already visible to Glaucous Gulls nesting nearby, and males were, in fact, able to provide additional nest defense in several cases.

Predators, too, failed to gain a fitness benefit during this study. There was no successful Glaucous Gull reproduction in either year. As the fox and non-resident gulls were, most likely, attracted to Egg Island by the concentration of Common Eiders, it appears that Glaucous Gulls, too, fell into an "ecological trap." Common Eider nests were highly vulnerable to depredation by locally nesting Glaucous Gulls (a single nesting pair of Glaucous Gulls consumed over one quarter of all eggs we saw eaten in 2003), so it follows that Common Eider eggs were an important food

source for breeding Glaucous Gulls on Egg Island. Yet, when unprotected eggs were most available (i.e., during the fox visit), non-resident gulls consumed the majority of eggs (including gull eggs), while breeding gulls were occupied with defense of their own nests. Ultimately, these locally breeding Glaucous Gulls failed reproductively, in spite of the apparent benefit of nesting in proximity to Common Eider nests.

Ultimately, Arctic Foxes caused the complete nest loss for all birds in this study, yet the fitness gained by the foxes was likely minimal. The foxes cached almost all the eggs and departed the island shortly after all nests were destroyed. It is doubtful that the cached eggs were ever recovered. To return to the island later in the season to retrieve cached eggs, foxes would face a longer, more arduous, swim due to continued sea ice retreat. Further, the barrier islands of the central Beaufort Sea experience substantial wave-battering and redistribution of sand and gravel from storms during the ice-free period. Thus, it is unlikely that intact cached eggs could be recovered even if the foxes returned to the island later in the season or after freeze-up.

Our results demonstrate that successful Common Eider and Glaucous Gull reproduction in the central Beaufort Sea can occur only in years when foxes do not have access to the barrier islands and even then nesting success of eiders is likely to be low (Quinlan and Lehnhausen 1982). Island access by foxes is unpredictable and can occur during any stage of nesting. These particular foxes were probably non-breeders as they were roaming the islands in July when breeders would be attending mainland dens. The number of non-breeding foxes fluctuates year-to-year; however, in the oilfields around Prudhoe Bay the degree of fluctuation has been dampened (Burgess 2000) and the number of fox dens and the average litter size have increased (Ballard et al. 2000; Burgess 2000). For this eider-gull nesting association to have evolved, the historical access of foxes to island nesting colonies must have been relatively rare (Ahlèn and Andersson 1970). These associations cannot persist on the barrier islands of the central Beaufort Sea if nesting success is consistently driven to near zero by a changed system in which the frequency of Arctic Foxes access to the islands is increased.

Despite the total nest failure caused by foxes, our observations provide information regarding rates of nest depredation by gulls in the absence of human disturbance. Gulls destroyed a fairly high proportion of nests during the egg-laying period, and some of these failed-early nests (often characterized by minimal down or nest bowl delineation) would probably go undetected by researchers searching for nests weeks later during the incubation stage. This has important implications for studies of nesting effort and success involving incubation-stage nest searches, as a bias against the detection of failed nests would lead to biased estimates of these parameters. Overall, even in the absence of human disturbance, the nesting productivity of Common Eiders on the barrier islands of the central Beaufort Sea is low due to the impact of avian and mammalian predators.

Acknowledgments

We thank J. Arnold, C. Crews, A. Farris, S. Iverson, D. Koontz, T. Pearson, L. Skerratt, S. Sonsthagen, and S. Wallace for field assistance. Particular thanks go to R. Lanctot, K. Cairns, W. Cullor, J. Sarvis, W. Streever, and ERA Helicopters, Inc., for logistical support of this project. S. Are, A. Erskine, T. Fondell, H. Wilson, and two anomynous reviews provided helpful comments on earlier versions of the manuscript. Sheaffer, Susan E., Richard A. Malecki, Bryan L. Swift, John Dunn, and Kim Scribner. 2007. Management implications of molt migration by the Atlantic Flyway resident population of Canada Geese, *Branta canadensis*. Canadian Field-Naturalist 121(3): 313-320.

We used satellite-tracked transmitters in 2001 and 2003 to document the timing, location, and extent of molt migrations by female Canada Geese (*Branta canadensis*) affiliated with the Atlantic Flyway Resident Population (AFRP) of Canada Geese that breed in the temperate region of eastern North America. Twenty-seven adult females were captured during the nesting period in late May and fitted with a satellite transmitter mounted either on a plastic neck collar or backpack harness. Nests of 24 birds were destroyed late in incubation to prevent renesting and ensure nest failure; three females did not have nests. Twelve of the 27 birds (44%) made a northward migration to molt in northern Quebec, Canada: seven to the eastern coast of Hudson Bay (58°12'N, 76°60'W), three to lowland areas east of James Bay (53°30'N, 79°02'W), and two to interior locations south of Ungava Bay (55°54'N, 68°24'W). Molt migrants were present in northern Quebec from June to September, a period that coincides with breeding ground aerial surveys and banding operations conducted for Atlantic Population (AP) Canada Geese that breed in this same region of northern Quebec. With >1 million AFRP geese estimated in the Atlantic Flyway, the potential exists for substantial numbers of yearling, sub-adult, and nest-failed or non-breeding adults to molt migrate to northern breeding areas and bias efforts to survey and mark AP geese. Within AFRP breeding areas, many local flocks have reached nuisance levels. We hypothesized that by inducing molt migration in breeding adults, through destruction of nests late in incubation, we would lessen recruitment, reduce numbers of summer resident adults with young, and increase adult mortality from hunting. However, molt migration behavior was not uniform throughout our study area. Molt migrants were from rural areas in New York, Pennsylvania, and Vermont, whereas marked birds that did not make molt migrations were from more coastal regions of the flyway. The 14 birds that did not make a molt migration remained within 60 km of their banding site. A genetic comparison of these two groups revealed no detectable differences. We conclude that failure to undergo a molt migration is likely attributed to the historical origin of captive-reared birds of mixed subspecies that comprise AFRP flocks in the eastern regions of the flyway and the availability of quality local habitat, distinct from brood-rearing areas, for molting.

Key Words: *Branta canadensis*, Canada Geese, molt migration, temperate-nesting, Resident Population, Atlantic Flyway.

Canada Geese (*Branta canadensis*) often undergo a late spring migration, flying long distances from their breeding locations to more northerly areas, where they undergo an annual molt. A form of molt migration, these movements have been documented for Canada Geese from both subarctic-nesting populations, which typically breed in remote areas of northern Canada (Sterling and Dzubin 1967; Abraham et al. 1999), and temperate-nesting populations, that breed in southern Canada and the United States (Zicus 1981; Davis et al. 1985; Lawrence et al. 1998). Birds that undergo a molt migration are primarily nonbreeding subadults and unsuccessful breeding adults (Salomonsen 1968; Lawrence et al. 1998).

There are two subarctic-nesting populations (Atlantic Population [AP] and North Atlantic Population [NAP]) associated with the states of the Atlantic Flyway, whereas temperate-nesting geese are collectively recognized as the Atlantic Flyway Resident Population (AFRP; Atlantic Flyway Waterfowl Council 1999*). Because these populations are mostly indistinguishable when they mix in the field on migration routes and wintering locations, their population and harvest management depends on monitoring efforts directed at their population-specific breeding areas. For example, annual assessments of population size are dependent on spring aerial surveys of breeding areas. However, movement of molting groups of temperate-nesting geese from Michigan to subarctic breeding areas in northern Canada has been confirmed through monitoring with satellite-tracked transmitters (Mykut et al. 2004). If molt migrations by temperate-nesting geese occur while spring surveys are being conducted on northern breeding grounds, then population estimates for subarctic-nesting populations can be positively biased by the inclusion of molt migrants (Abraham et al. 1999).

Similarly, population-specific assessments of harvest rely on band recoveries obtained from birds marked on their breeding grounds as flightless adults and young. In recent years, recaptures on subarctic breeding grounds of previously banded adults and young from temperate-nesting areas (Abraham et al. 1999; Nichols et al. 2004) have raised concern over the potential bias in the banded samples of subarctic-nesting geese. Molt migrations of temperate-nesting geese to northern breeding areas can also increase competition for resources and potentially degrade brood-rearing habitat for subarctic-nesting geese. Previous studies have demonstrated that a large proportion (50% – 60%) of temperate-nesting flocks potentially undergo a molt migration (Zicus 1981; Lawrence et al. 1998). Given that estimated numbers of temperate-nesting geese currently exceed 1 million birds in each of the Mississippi and Atlantic flyways (United States [U. S.] Fish and Wildlife Service 2007*), the potential problems with survey efforts and impacts to habitat could be substantial.

Temperate-nesting Canada Geese also are of concern within their breeding range, where they often occur in areas with few natural predators. Because of their relatively high survival and stable reproductive rates, local flocks can rapidly reach nuisance levels in urban areas and rural areas with low harvest pressure. Given that some unsuccessful breeders undergo a molt migration, we reasoned that deliberate nest destruction late in the incubation period, to ensure nest failure, would induce these birds to molt migrate. This procedure has the potential to reduce annual recruitment of young into the population, lessen the number of adults and young residing in local areas during the summer, and expose this component of the population to hunting pressure in other regions when they return in the fall. Our objective was to assess both the efficacy of this technique and to monitor the resultant timing, locations, and extent of molt-migration movements as they relate to management of AFRP Canada Geese in the Atlantic Flyway.

Methods

In 2001, eight female Canada Geese were captured at four locations in New York during late May (Table 1). Nests of five birds were destroyed during the last 7-10 days of incubation; no nests were detected for three of the eight (Table 1). Each goose was fitted with a 30 g satellite-tracked transmitter (PTT Model 100, Microwave Telemetry, Inc., Columbia, Maryland; mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government) attached dorsally with a harness constructed of Teflon ribbon. Transmitters had specifications for ~480 hours of battery life and were programmed to transmit for an eight-hour period every four days. Expected battery life was about eight months.

We expanded the study in 2002 to include 19 nesting females captured under similar nesting conditions in New York (n = 4), Pennsylvania (n = 6), New Jersey (n = 4), Massachusetts (n = 2), Connecticut (n = 1), Vermont (n = 1), and Maine (n = 1). To simplify attachment procedures and reduce costs, we switched to transmitters mounted on plastic neck collars produced by Telonics, Inc. of Mesa, Arizona. Program features were similar to those used in 2001. Unfortunately, most of the transmitters deployed in 2002 did not provide sufficient signals to the satellites to produce usable locations. The 2002 transmitters were replaced by the manufacturer and 19 nesting females were marked in 2003: New York (n = 4), Pennsylvania (n = 4), New Jersey (n = 4), Massachusetts (n = 2), Connecticut (n = 2), Vermont (n = 1), Maine (n = 1), and Maryland (n = 1) (Table 1).

Data from the radio transmitters were obtained from the Argos satellite system of the French Space Agency via a preferential tariff agreement with the U. S. Department of Commerce's National Oceanic and Atmospheric Administration. Location estimates were classified by Argos based on their estimated accuracy and the number of transmissions received from a transmitter during a satellite overpass. Location classes 3, 2, and 1 had accuracy ratings within 1000 m. Accuracy for location class 0 was >1000 m, and location classes A and B did not receive enough transmissions during an overpass for accuracy to be estimated (Service Argos 1996*). However, Britton et al. (1999) demonstrated that poor locations (classes 0, A, and B) received from satellite transmitters (30 g) averaged 35 km from the true location of the transmitter. We therefore included all locations with a classification of 3, 2, 1, 0, A, or B, because the accuracy of these classes was sufficient to describe large-scale movements.

Argos estimated locations by measuring the Doppler shift of the received signals, which produces two pairs of latitude and longitude coordinates from an individual satellite overpass. Argos designates the location with the better frequency continuity as the most probable location (location 1), and the alternate location is designated as the image (location 2). Examination of our data occasionally indicated that sometimes location 2 was a more probable fix than location 1 based on the flight dynamics of Canada Geese. We developed a sorting routine similar to that of Britton et al. (1999) that sequentially examined the location pairs to identify locations that appeared most probable. The initial location for each bird was the site of banding. For each subsequent pair of locations, flight speed (distance/hr) was calculated from location 1 in the previous location pair to location 1 of the next location pair. If the bird had flown <65 km/hr to reach both locations 1 and 2, we selected location 1. If the bird had flown >65 km/hr to reach location 1, but <65 km/hr to reach location 2, we selected location 2. If both locations violated our 65 km/hr rule, we deleted both. We retained all locations with an accuracy classification of 3, 2, and 1. When an 8-hour transmission period contained only locations with a classification of 0, A, and B, we esti-

mated one location for that period as the centroid of the most probable latitude and longitude coordinates.

During the course of our study, we hypothesized that the differential propensity to undergo a molt migration could be related to genetic differences among geese from interior and coastal areas comprising our sample. In 2004, we attempted to test this by collecting blood samples from molting adult geese with young in rural areas of central New York (n = 15) and Pennsylvania (n = 15) and compared these with similarly collected samples from more coastal and urban/suburban areas of Long Island, New York (n = 5), New Jersey (n = 15), Massachusetts (n = 5), and Connecticut (n = 5). Genetic testing of microsatellite markers and mitochondrial DNA was done using methods described by Scribner et al. (2003a).

We used seven microsatellite loci that have previously been described for Canada Geese for other populations across North America (Scribner et al. 2003a, 2003b). Loci included TTU-CG-1, TTU-CG-5 (Cathey et al. 1998) and Bcaμ7, Bcaμ9, Bcaμ11, and Hhi1, (Buchhollz et al. 1998), and CRG (Baker, unpublished data). After electrophoresis on denaturing 6% acrylamide gels, PCR products were visualized using an FMBIO II laser scanner (Hitachi Software Engineering Co., Alameda, California). Genotypes were scored based on 20 base-pair standards and reference samples of known allelic size.

We obtained sequence information from a ≈ 385 base-pair (bp) fragment of the 5' end of the Canada Goose mitochondrial DNA control region using primers and conditions described in Pearce et al. (2000). Sequencing was performed using a SequiTherm Excel DNA sequencing kit (Epicentre, Inc.), following product protocols for use of fluorescently labeled primers. Sequences were aligned manually.

We estimated degree of differentiation in allele and haplotype frequency between Canada Geese sampled from coastal and interior regions using a Fisher's exact test in program GENEPOP and using F-statistics (Weir 1996) using the program F-STAT (Goudet 1995). Measures of inter-population variance in allele frequency were summarized as pair-wise estimates of population F_{st}. Significance of mean F_{st} values (across the seven loci) were determined by jack-knifing procedures (Weir 1996). Analyses of population differences in mtDNA haplotype frequency were conducted using an analysis of molecular variance (Excoffier et al. 1992).

Results

Of the eight birds marked in New York in 2001, seven made molt migrations to areas in Quebec, Canada: four traveled to the eastern coast of Hudson Bay (58°12'N, 76°60'W), two went to lowland areas east of James Bay (53°30'N, 79°02'W), and one moved to an interior location ~350 km southwest of Ungava Bay (56°06'N, 70°04'W) (Figure 1). Locations from four transmitters deployed in 2002 (two from Pennsylvania, one from New York, and one from Vermont) suggested that these birds also made a molt migration to northern Quebec; however, the data were not sufficient to identify migration timing or provide reliable locations.

NY = New York, CT = Connecticut, PA = Pennsylvania, MD = Maryland, ME = Maine, MA = Massachusetts, NJ = New Jersey, VT = Vermont

Only five of the 19 birds marked in 2003 made molt migrations to northern Quebec (three from Pennsylvania, one from New York, and one from Vermont). Three traveled to the eastern coast of Hudson Bay (58°12'N, 76°60'W), one went to eastern James Bay (53°54'N, 79°00'W), and one moved to an interior location south of Ungava Bay (57°00'N, 74°36'W) (Figure 1). The 14 females that did not make a molt migration exhibited little movement during June through early November; movement of these geese was limited to within 60 km of the banding site. All of the birds that did not make a molt migration were from more coastal regions of the flyway (Figure 2).

Molt migrations in both 2001 and 2003 occurred in June. Marked geese that molt migrated (n = 12) were located in the U.S. as late as 30 May – 20 June. They arrived at terminal locations in northern Quebec (Fig-

ure 1) between 9 and 26 June. Fall migration of these molt migrants occurred primarily in September. Birds were located in northern Quebec as late as 28 August – 29 September. They arrived in southern Canada or the U.S. between 6 September and 3 October (Figure 3). There was no distinguishable difference in timing of molt and fall migrations between marked geese in 2001 and 2003. Molt migrations ranged in distance from 564 – 1941 km (Table 1).

Genetic analysis of the two groups of geese showed no evidence across loci of significant differences in microsatellite allele frequency ($F = 0.005$, $P > 0.05$). Likewise, analysis of variance results for mtDNA haplotype frequencies also revealed no evidence of significant differences between the two groups ($\Phi = 0.00$, $P > 0.40$). When analyses were extended to include reference samples from the two subarctic-nesting Canada Goose populations (AP and NAP), we observed differences in allele frequencies among all three populations for both microsatellite loci and mtDNA haplotype ($P < 0.05$ for both markers).

Discussion

Our results provide convincing evidence of the movement of some molting AFRP geese to the northern breeding ground of AP geese at a critical time during the spring population monitoring and summer prehunting season banding periods. Zicus (1981) and Lawrence et al. (1998), working with temperate-breeding Canada Geese in Wisconsin and Illinois, each reported 50-60% of their spring population departing on molt migrations. Mykut (2002) satellite-tracked female Canada Geese in Michigan, whose nests were destroyed, as in this study, late in incubation. He found 62% ($n = 37$) in 2000 and 73% ($n = 52$) in 2001 of these birds molt-migrating to James and Hudson Bays in northern Canada. The literature is replete with other reports of long distance molt migrations in temperate-nesting geese.

The propensity to molt migrate, observed in nest-failed females from rural New York and Pennsylvania, but not for birds nesting in more coastal areas of the flyway, prompted us to suspect a possible genetic difference resulting from regional differences in the origin of these birds. Blandin and Heusmann (1974) reported that geese breeding in eastern Massachusetts were of mixed racial stock, nonmigratory in nature, and the progeny of decoy birds released in the late 1930s. Morphometric measurements of these birds (Pottie and Heusmann 1979) indicated a probable mixing of several sub-species, in which *B. c. maxima* (Giant Canada Goose) predominated. In contrast, geese in rural New York and Pennsylvania are primarily large Canada Geese of the *B. c. maxima* and *B. c. moffitti* (Great Basin Canada Goose) stock introduced after the 1950s to areas previously devoid of breeding geese. These birds may be more similar to mid-continent temperate-nesting populations of restored or reintroduced giant Canada Geese. Molt migration in giant Canada Geese is considered a common behavior (Abraham et al. 1999). We were able to detect genetic differences of sufficient magnitude to discern the AFRP geese we sampled from subarctic-nesting populations of geese occurring in the flyway (AP and NAP), but we did not detect genetic differences between the two regional cohorts sampled within the AFRP.

Two factors favoring movement of waterfowl to remote regions to molt are the reduced risk to survival and greater food availability (Hohman et al. 1992; Baldassarre and Bolen 2006). In Canada Geese, successful breeders also are often behaviorally dominant over nonbreeders (Raveling 1970), which may influence movement of the nonbreeding segment away from nesting areas. However, in New Jersey, Nichols et al. (2004) estimated that only 22-31% of resident Canada Geese migrated out of the state to molt. They suggested that birds in and near urban-suburban dominated landscapes may have many suitable molting sites consisting of large expanses of lush, fertilized lawns interspersed with water bodies and few predators. The gathering of nonbreeders into larger flocks to molt on or near breeding areas may also lessen stress associated with behavioral interactions of adults with young. Lawrence et al. (1998) also noted that in more recent times, with greater emphasis on hunting of temperate-nesting geese to manage their numbers, birds leaving the sanctuary of local breeding areas are more likely to be harvested.

The coastal region of our study, from which molt migration did not occur (Connecticut, Massachusetts, Maryland, and New Jersey), contains ~21% ($N = 245351$) of the AFRP spring population estimate (United States Fish and Wildlife Service 2007*) in the U.S. Geese in New York, Pennsylvania, and Vermont make up ~45% ($N = 514181$) and the coastal states of Delaware and Virginia, where geese were not sampled as part of this study, comprise ~14% ($N = 163655$). If we assume that 50% of the geese in New York and Pennsylvania are molt migrant non-breeders or unsuccessful breeders (Zicus 1981; Lawrence et al. 1998), then the potential exists for a substantial movement of geese (≥250 000) to subarctic breeding areas in northern Canada. This number is further increased by temperate-nesting birds moving into subarctic regions from the Mississippi Flyway.

The population estimate for AP geese in northern Quebec, where we suspect most AFRP birds molt migrate to, is ~1.2 million (Harvey and Rodrique 2007*). However, the authors caution that differences in survey timing and the abundance of molt migrants can clearly introduce substantial variability in the total population estimate. Similar conflicts are reported by Abraham et al. (1999) for Southern James Bay Population Canada Geese in northern Ontario. Spring surveys of AP geese are timed to cover the mid to late incubation period; generally the last two weeks in June. Arrival of AFRP

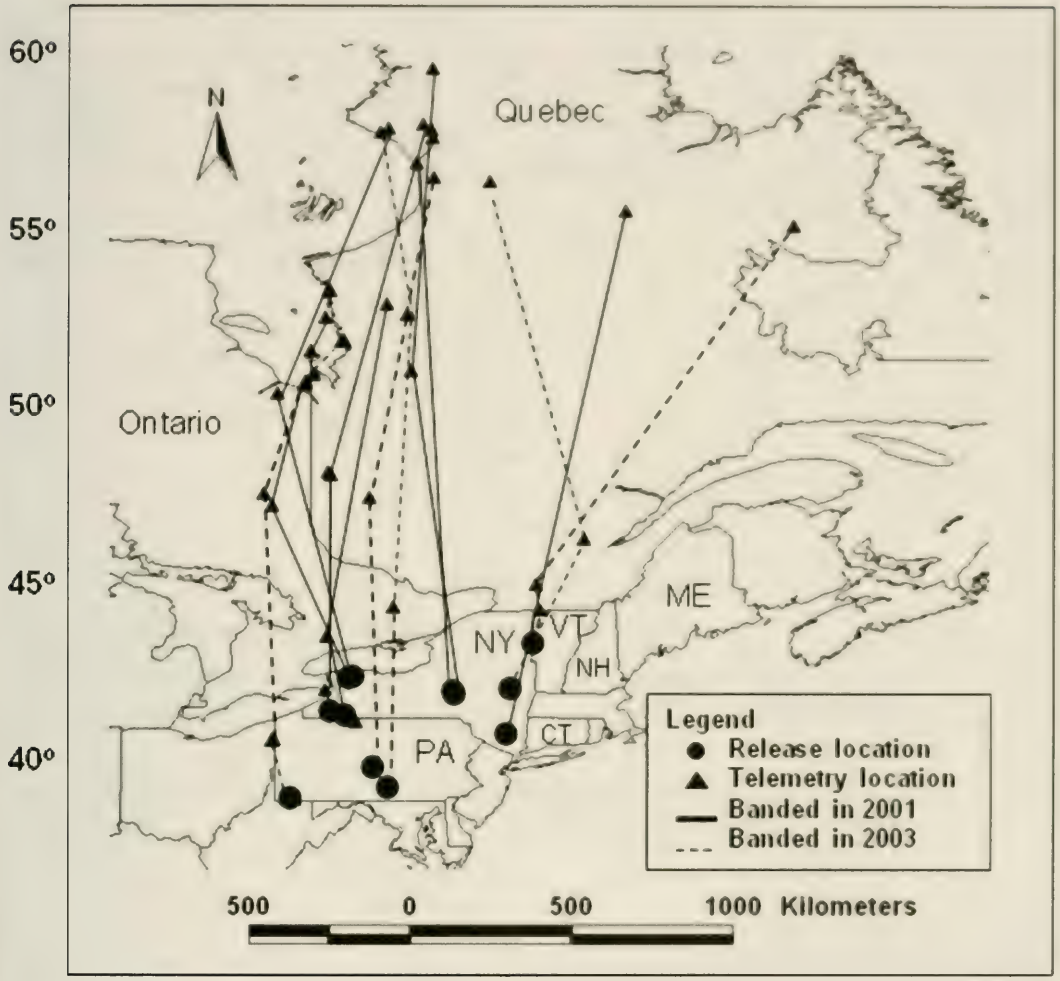

FIGURE 1. Locations of Atlantic Flyway Resident Population Canada Geese during spring molt migration in 2001 and 2003. Locations were identified using birds marked with satellite-tracked transmitters. Birds arrived at terminal molting areas in northern Quebec between 9 June and 16 June.

molt-migrants coincides very closely with the beginning of these surveys. Similarly, summer banding of AP geese, which usually takes place in late July – early August, also occurs when molt migrants are still on the AP breeding grounds. Given that molting large Canada Geese can require up to 40 days to obtain the 85% of primary feather development required to regain flight (Hanson 1965), geese arriving in mid-June have the potential still to be flightless when subarctic-breeding adults with young are being banded. This mixing of populations re-enforces the need to (1) monitor the status of subarctic-breeding populations using numbers of breeding pairs surveyed, rather than total counts involving groups of geese of unknown origin, and (2) band only flightless adults with young during the summer pre-season banding period to ensure a representative sample of subarctic-nesting populations of Canada Geese.

In the late 1980s, as an aid in the control of increasing numbers of temperate-nesting geese, the U.S. Fish and Wildlife Service endorsed the implementation of special hunting seasons in September and late-winter, when subarctic-nesting goose populations would be less likely affected (Heusmann et al. 1998). While effective in many rural areas, geese in urban and suburban environments often receive little exposure to hunter harvest (Smith et al. 1999). Efforts to control nuisance geese generally rely on non-lethal methods involving addling and oiling of eggs in nests (Christens et al. 1995) and harassment techniques to move birds from heavily used residential and industrial areas (Holevinski et al. 2007). Both methods provide only a moderate degree of relief, at best.

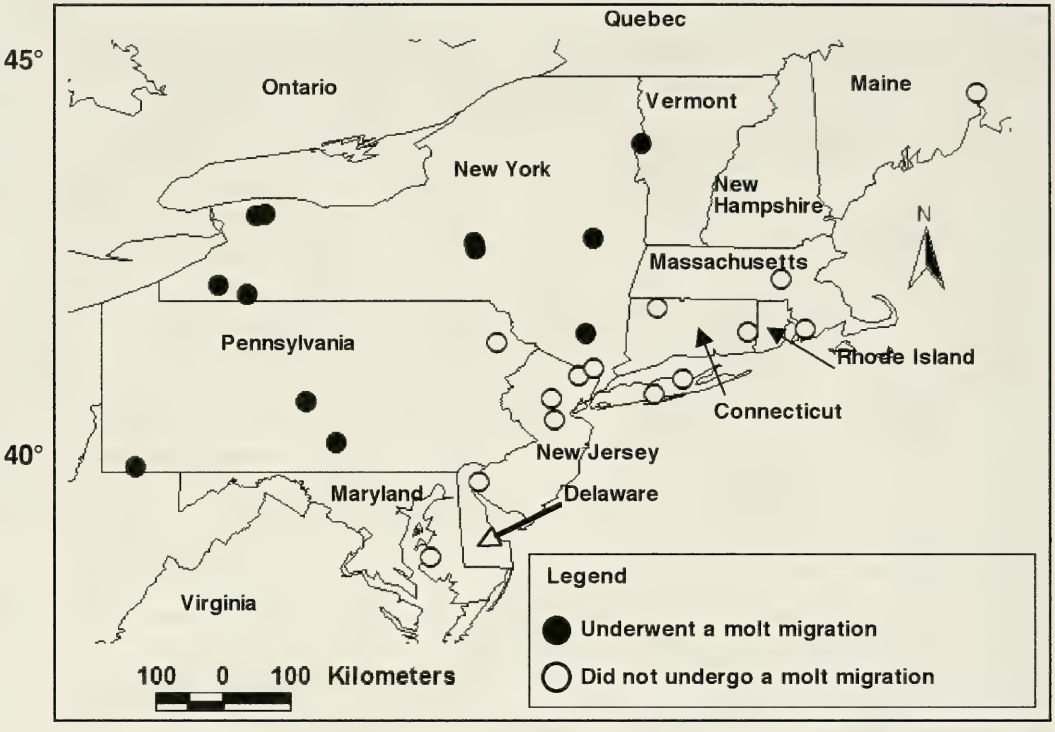

FIGURE 2. Banding locations of Atlantic Flyway Resident Population Canada Geese marked with satellite-tracked transmitters during May 2001 and 2003.

Many studies have demonstrated that altering survival of adult geese is much more effective in changing population size than altering recruitment rates (Trost et al. 1986; Schmutz et al. 1997). However, direct culling of molting birds continues to remain a socially unacceptable option for population control in many areas. One alternative, transplanting flightless adults with young from nuisance areas to rural areas prior to the fall hunting season, successfully reduced survival of adults in comparison to non-transported birds, but was both time consuming and costly (Holevinski et al. 2006). Inducing molt migration of adult breeding geese by destroying nests late in incubation, as demonstrated in this study, showed potential for both removal of birds from their breeding area during the spring and summer period and exposing them to hunting outside the region. However, our failure to demonstrate this in coastal areas, which have more prominent nuisance Canada goose issues, was problematic. We can only assume that the reason for this was attributed to the historical origin of captive-reared birds of mixed subspecies making up AFRP flocks in this part of the flyway and the availability of quality local molting habitat distinct from brood-rearing areas.

Dalén, Love, Anders Götherström, Tomas Meijer, and Beth Shapiro. 2007. Recovery of DNA from footprints in the snow. Canadian Field-Naturalist 121(3): 321-324.

The recovery of trace amounts of DNA has been demonstrated to be a reliable tool in conservation genetics and has become a key component of modern forensic casework. To date, genetic data have been successfully recovered from a variety of sources, including biological fluids, faeces, clothing, and even directly from fingerprints. However, to our knowledge and despite their widespread occurrence and clear potential as a source of DNA, genetic information has not previously been recovered directly from footprints. Here, we extract and amplify mitochondrial DNA from a snow footprint, <48-hours old, made by a Swedish Arctic Fox (*Alopex lagopus*). Our results demonstrate that it is possible to recover sufficient DNA from recent footprints to accurately type the source of the print, with implications for conservation biology and forensic science.

Key Words: Arctic Fox, *Alopex lagopus*, Red Fox, *Vulpes vulpes*, trace DNA, conservation biology, forensics.

Both conservation and forensic genetics rely on the ability to retrieve data from material containing only minute amounts of DNA. In forensic studies, key data are often generated from small amounts of biological tissue or liquids recovered from crime scenes (Bond 2007). Conservation geneticists are often interested in applying non-invasive sampling techniques in their research, many of which also target low copy-number biological sources such as hair or faeces (DeSalle and Amato 2004). Methods for recovering trace amounts of DNA have been fine-tuned over the last decade, resulting in the successful amplification of DNA from a variety of sources. For example, previous work has shown that it is possible to recover nuclear DNA from items of worn fabric, such as clothing and the insoles of shoes (Wickenheiser 2002; Bright and Petricevic 2004), and from other fabrics such as bedding (Petricevic, Bright, and Cockerton 2006). Hair shafts and faeces (Kohn and Wayne 1997) from humans, animals, and even ancient specimens (e.g., Higuchi et al. 1988; Gilbert et al. 2004; Pfeiffer et al. 2004; McNevin et al. 2005), fingernails and fingernail scrapings (e.g., Oz and Zamir 2000), and latent fingerprints (e.g., van Oorschot and Jones 1997; Alessandrini et al. 2003; Balogh et al. 2003) have also been shown to be good sources of both mitochondrial DNA (mtDNA) and nuclear DNA.

It is well known that DNA survival is affected by ambient temperature, with the greatest probability of survival occurring in locations with constant low temperatures (Smith et al. 2003). It is therefore conceivable that should biological material be deposited in ice or snow this frozen environment would provide ideal conditions for DNA survival. Potential sources of DNA in ice or snow include shed cells, hair, and biological fluids. However, previous attempts to isolate DNA from randomly selected patches of ice and snow have shown that DNA is rare in the general environment (Hansen and Willerslev 2002). Nonetheless, if it were possible to identify patches in which DNA is concentrated, the combination of cold preservation and the purity of the sample should make these patches an excellent source of genetic information.

The ability to amplify DNA from fingerprints has shown that a few shed skin cells are sufficient for genetic typing. Footprints made by people or animals should therefore be equally viable sources of DNA; however, the nature of the location of footprints (on the ground, mixed with myriad other genetic data) has made this hypothesis difficult to test. Footprints made in snow, however, are unlikely to be contaminated by other sources of DNA or chemical inhibitors. Here, we investigate whether it is possible to recover DNA directly from animal footprints made in snow, and discuss the potential of such an approach for forensic science and conservation biology.

Materials and Methods

Six samples from fresh (<48h old) fox tracks were collected in Jämtland County, Sweden, during the winter in 2006. Samples were taken from different tracks, so as to minimise the risk of sampling the same individual twice. Each imprint was carefully excavated from the snow using sterile equipment and put into 50 ml Falcon tubes. Three additional samples were taken from undisturbed snow, for use as negative controls. Due to the possibility of low DNA yields from footprints, and ensuing risk of contamination, the DNA extractions were done in a dedicated ancient DNA

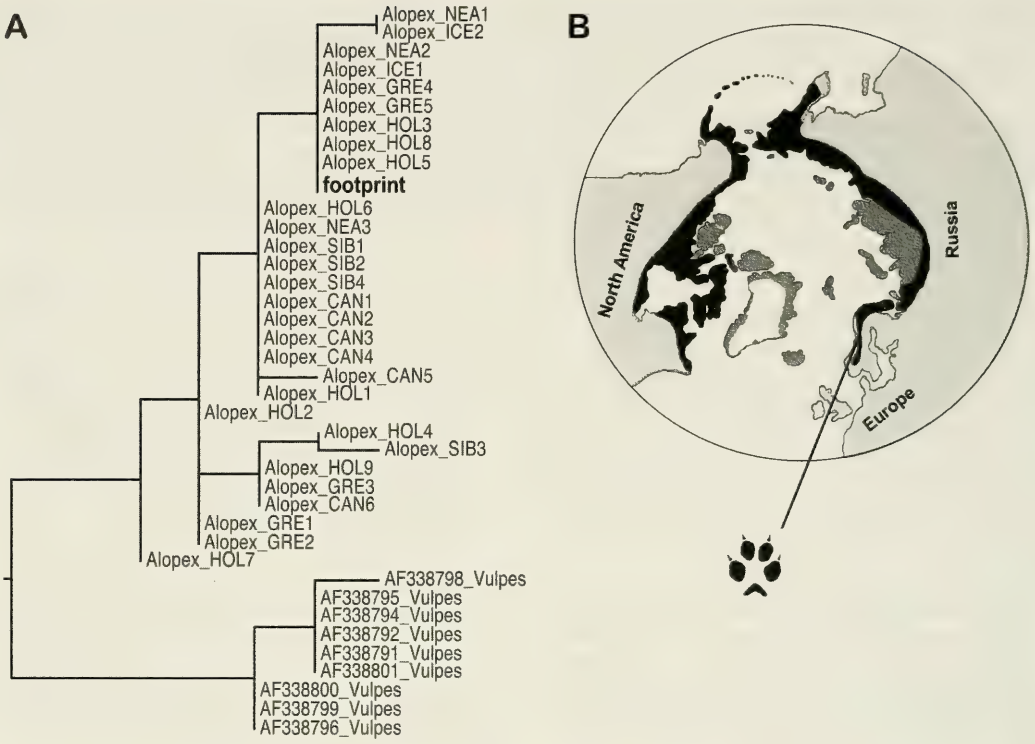

FIGURE 1. (A) Maximum liklihood tree describing the relationships between mitochondrial DNA sequences from Arctic Foxes, Red Foxes, and that recovered from the footprint in central Sweden. Details of the phylogenetic analysis and statistical support are given in the text. (B) Map showing the Holarctic distribution of the two species of fox. Lighter and dark grey shading indicates the distribution of the Red Fox and Arctic Fox, respectively, and black shading indicates where the two ranges overlap. The line indicates the location in Sweden from which the footprints were recovered.

facility in Madrid, Spain. The samples were concentrated using 15 ml Amicon filters (Millipore Massachusetts, USA) and extracted from the resulting filtrate following the protocol by Yang et al. (1998), as modified by Svensson et al. (2007). An approximately 150 base pair (bp) fragment of the mitochondrial control region was amplified using primers Pex3F and H3R (Dalén et al. 2007). Resulting PCR products were sequenced using the Big Dye Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems, California, USA) and analysed on an Applied Biosystems 3730xl sequencer following the manufacturer's instructions.

Previously published Arctic Fox (*Alopex lagopus*) and Red Fox (*Vulpes vulpes*) mitochondrial DNA sequences covering the length of the 150-bp amplifid fragment were collected from GenBank (accession numbers AF338791-AF338792, AF338794-AF338796, AF338 798-AF338801, AY321120-AY321148) and aligned by eye. A Maximum Likelihood (ML) phylogenetic analysis was performed using the program PAUP v4.10b (Swofford 1999). An HKY model of nucleotide substitution was assumed, so as to allow for different rates of transitions and transversions along the sequences. Starting trees were generated by neighbor-joining (NJ), from which subsitution parameters were estimated and fixed. Heuristic searches were then performed using the estimated substitution parameters and SPR branch swapping. Substitution parameters were then re-estimated from the most likely trees and the analysis was repeated. Figure 1 shows the resulting ML tree describing the relationship of the sequence amplified from the footprint with Arctic and Red foxes. The two clades are separated by bootstrap (100 full heuristic runs, with starting trees generated by NJ and NNI branch swapping) support values of 96%.

Results

Mitochondrial DNA was recovered from one of the six footprints from which snow was collected. While it has been shown recently that DNA can be recovered from faecal and hair samples collected along animal

tracks (Ulizio et al. 2006), this is the first report of DNA being recovered directly from the tracks themselves. Identification of species from tracks presents an important resource for conservation and management of rare species. In this case, both Arctic and Red foxes inhabit the Swedish mountain tundra, and the footprint could thus have derived from either of the two species. However, the resulting mtDNA sequence showed that the footprint originated from an Arctic Fox (Figure 1) and was identical to one of the three mtDNA haplotypes that exist today in Sweden (Dalén et al. 2005).

Discussion

While the overall success of this initial study was small, it is worthwhile to note that, in this case, only one footprint was sampled from each track. If this method were to be applied in a forensic or conservation genetics context, it would be reasonable to sample several footprints from the same track, significantly increasing the potential for DNA recovery. While this approach would increase the volume of snow or other substrate from which the biological material must be recovered, modern filtration devices such as those employed in this study make it feasible to concentrate large volumes in relatively little time.

The ability to recover DNA from footprints has implications for many areas of research that rely on the ability to amplify low copy number DNA. For example, DNA from footprints could be used to identify individual carnivores that prey on livestock, or to link animal prints found at a crime scene to a specific individual. In conservation genetics, this method makes it feasible to follow individual movements across a landscape, and to directly establish the dimensions of individual home ranges. Perhaps most importantly, the amplification of DNA from footprints could serve as an additional source of non-invasive sampling, complementing conventional materials such as faeces (Höss et al. 1992), hair (Taberlet et al. 1993) and urine (Valiere and Taberlet 2000), and potentially avoiding many of the problems with inhibition that are associated with these sources of DNA.

Price, Michael H. H., and Clare E. Aries. 2007. A River Otter's, *Lontra canadensis*, capture of a Double-crested Cormorant *Phalacrocorax auritus*, in British Columbia's Gulf Island Waters. Canadian Field-Naturalist 121(3): 325-326.

Direct and apparent predation events by River Otters (*Lontra canadensis*) on birds have been recorded on marine islands and freshwater lakes. We add to this the first known observation of a River Otter capturing a marine bird on the ocean.

Key Words: River Otter, *Lontra canadensis*, diet, birds, foraging, conservation, coastal, islands, British Columbia

The River Otter (*Lontra canadensis*) is a largely piscivorous carnivore inhabiting riparian areas, coastal shorelines, and archipelagos of North America (Cowan and Guiguet 1965). Their diets have been well described along inland river systems and lakes (Sheldon and Toll 1964; Knudsen and Hale 1968; Reid et al. 1994), yet little is known about their ecology in marine communities. Nevertheless, fishes are their primary food in all habitats (Lagler and Ostenson 1942; Stenson et al. 1984; Bowyer et al. 1994). Birds are considered rare and sporadic food items (Toweill 1974; Stenson et al. 1984).

Early reports of bird remains in the stomachs or faeces of River Otters suggested that they scavenged carcasses (Lagler and Ostenson 1942; Sheldon and Toll 1964). Years later, it was postulated that River Otters probably consume wounded or incidentally killed birds hunted by humans (Toweill 1974). In coastal British Columbia, Washington, and Alaska, however, researchers have recently described predation events by River Otters on nesting marine birds (Hayward et al. 1975; Foottit and Butler 1977; Verbeek and Morgan 1978; Quinlan 1983; Speich and Pitman 1984; Duffy 1995). We herein describe a River Otter's successful aquatic capture of a Double-crested Cormorant (*Phalacrocorax auritus*) in marine waters.

At approximately 1130 hours on 18 February 2005, a family of four River Otters [one adult – three juveniles] swam in an unnamed cove adjacent to Swartz Bay, Vancouver Island (48°42'N, 123°25'W). The sky was overcast, and the sea and winds were calm. At this time, we also observed a mixed raft of approximately 120 Double-crested and Pelagic (*P. pelagicus*) cormorants and Pacific Loons (*Gavia pacifica*) situated 400 meters from the River Otters to the north. The birds drifted east with the current, roughly 100 meters south of Piers Island. They consistently dived and surfaced, presumably feeding on small fishes [Pacific Sandlance (*Ammodytes hexapterus*) or Pacific Herring (*Clupea pallasii*)].

The four River Otters swam directly towards the raft with their heads above water. When within 50 meters, all Otters dived in succession; apparently the foraging birds failed to detect their approach, as they continued to dive and surface. Less than two minutes later, a lone River Otter began swimming south to the unnamed cove with its head above water, towing a large object in its mouth. It dived, and re-surfaced less than 3 meters from our viewing platform with a gasping Double-crested Cormorant held by its throat. The River Otter then swam beneath a shoreline cabin, directly adjacent to a known den-site, and presumably fed upon its prey. We failed to observe the juvenile River Otters from that point on, and saw no evidence of them joining the adult to consume the cormorant. We also saw no physical evidence [i.e., carcass or feathers] after the event.

Observations of River Otters preying on birds are rare and almost exclusively observed on land or freshwater. For example, River Otters have ambushed nesting Glaucous-winged Gulls (*Larus glaucescens*), Aleutian Terns (*Sterna aleutica*) (Hayward et al. 1975; Foottit and Butler 1977; Verbeek and Morgan 1978; Duffy 1995), and Slavonian Grebes (*Podiceps auritus*) (Perkins et al. 2005), and preyed on incubating Storm-petrels [(*Oceanodroma furcata* and *O. leucorhoa*)] by digging them out of nesting burrows (Quinlan 1983). River Otters have also been observed preying on moulting American Widgeon (*Anas americana*) and Green-

winged Teal (*A. crecca*) on a freshwater lake in Alberta (Reid et al. 1994), and a Common Gallinule (*Gallinula chloropus*) on a slurry pond in Florida (Meyerriecks 1963). To our knowledge, this is the first observation of a River Otter preying on a bird on the ocean.

Acknowledgments

We thank the Coast Salish peoples for the use of their traditional territory, the Price family for use of their research cabin, and C.T. Darimont and two anonymous reviewers for improving the manuscript.

Chubbs, Tony E., and Frank R. Phillips. 2007. Winter occurrences of Ivory Gulls, *Pagophila eburnea*, in inland Labrador. Canadian Field-Naturalist 121(3): 327-328.

Ivory Gulls were observed during winter on three occasions up to 325 km inland from open coastal water, feeding on Caribou carcasses in inland Labrador. Other recent observations in central Labrador are also noted.

Key Words: Ivory Gulls, *Pagophila eburnea*, range, distribution, Labrador.

The Ivory Gull (*Pagophila eburnea*) is a plump, medium-sized gull (40-43 cm long; 108-120 cm wing span), about 10% larger and longer-winged than the Black-legged Kittiwake (*Rissa tridactyla*), with sexes alike and plumage entirely white in adults (Haney and MacDonald 1995). Ivory Gulls are High Arctic birds that have a circumpolar distribution ranging across northern Canada, Greenland, and arctic western Europe (Haney and MacDonald 1995; Gilchrist et al. 2005). The known Canadian population breeds in remote locations on Ellesmere, Devon, Seymour, northwestern Baffin and Perley islands, Nunavut (Todd 1963; Haney and MacDonald 1995; Thomas and MacDonald 1987; Stenhouse et al. 2004; Gilchrist and Mallory 2005).

Ivory Gulls, locally referred to as "Ice Partridges" (Peters and Burleigh 1951) or "Ice-Gulls" (Tuck 1971), are uncommon winter visitors in coastal Labrador and northern Newfoundland (Todd 1963). They are rarely found far from drifting pack ice offshore in winter near the southern pack ice between Canada and Greenland (Haney and MacDonald 1995; Stenhouse et al. 2004). Ivory Gulls appear along the northeast coast of Newfoundland and Labrador in December, usually well offshore, but they are most abundant in March when they concentrate on Harp Seal (*Pagophilus groenlandicus*) whelping areas in the pack Ice (Tuck 1967, 1971). Historic inshore observations of Ivory Gulls in Newfoundland and Labrador have occurred along the northeast coast of insular Newfoundland between December and March (Tuck 1971) with fewer records along the Labrador coast (Todd 1963). The largest numbers of Ivory Gulls recently recorded in our region have been in southeastern Labrador and northern Newfoundland following strong northeast gales (P. Linegar, personal communication). Peters and Burleigh (1951) indicated that there were a number of reports of the "Ice Partridge" from interior localities in Newfoundland and one specifically from Badger, but those sightings were not confirmed. Several adult Ivory Gulls have been banded at sea off Cape Chidley, Labrador (Thomas and MacDonald 1987), and a band was recovered in 1940 at Port Hope Simpson, Labrador (52°30'N, 56°10'W) that was banded in Franz-Joseph Archipelago (North of Russia) six years previously (Tuck 1967, 1971). Occasionally, there have been anecdotal observations of Ivory Gulls at North West River, Labrador, during winter, where the water remains open (P. Linegar personal communication). A recent observation at North West River was of a single immature Ivory Gull on 16 March 2006 (J. Thomas, Department of Natural Resources, personal communication). An adult and an immature Ivory Gull were also observed on 10 and 17 February 2007 at Dry Island (53°42.00'N, 59°59.50'W) near North West River (S. Russell, personal communication).

The Ivory Gull is designated as Endangered in Newfoundland and Labrador under the province's Endangered Species Act (NL ESA Regulation 57/2, 2002*) and in Canada under the federal Species at Risk Act (SARA Schedule 1) (COSEWIC, April 2006*). Recent aerial breeding colony surveys in the eastern Canadian Arctic revealed an 85% decline in numbers of breeding Ivory Gulls since the early 1980s (Gilchrist and Mallory 2005; Gilchrist et al. 2005).

Our observations were made while travelling along the Trans-Labrador Highway between Happy Valley-Goose Bay and Churchill Falls in central Labrador. This area lies within the Lake Melville-High Boreal Forest ecoregion and is dominated by Black Spruce (*Picea mariana*) with lesser amounts of Trembling Aspen (*Populus tremuloides*), White Birch (*Betula papyrifera*), Balsam Fir (*Abies balsamea*) and White Spruce (*P. glauca*) in river valleys (Meades 1990*). This region has the most moderate climate in Labrador with mean average daily temperatures ranging from −14 to −18°C in February and +13°C in July. Average annual precipitation is 1100 mm with an average snowfall accumulation of 4 m (Meades 1990*).

On 8 March 2003, F. R. Phillips and F. Taylor observed an adult Ivory Gull along the Trans-Labrador Highway approximately 5 km west of Metchin River (53°26'N, 63°18'W). The Ivory Gull was feeding on Caribou (*Rangifer tarandus*) remains left by hunters of

the migratory George River Caribou herd. The observation was located approximately 325 km west of the nearest permanently open coastal water at Rigolet (54°11'N, 58°27'W), and nearly 400 km inland from the edge of the coastal ice pack.

On 23 March 2006 we observed an adult Ivory Gull near the same location as the sighting recorded in 2003. This Ivory Gull was at a campsite adjacent to the Trans-Labrador Highway, 10 km west of Metchin River (53°26'N, 63°21'W) where approximately 15 Innu hunters had recently harvested 58 caribou. The Caribou carcasses, laid on the snow, were intact with the hide, head and legs attached with only the entrails removed. The Ivory Gull was feeding on the exposed flesh and offal of the Caribou adjacent to the road. The hunters indicated that the Ivory Gull had been present and feeding on scraps of Caribou meat for several days, alternating feeding sites between the road and the Churchill River, where the animals were harvested. On 26 March 2006, F. R. P. returned to the Innu camp but did not observe the gull. The hunters indicated that they had last observed the Ivory Gull on 24 March 2006.

On the morning of 26 March 2006, T. E. C. observed an adult Ivory Gull adjacent to his home in the community of Happy Valley-Goose Bay (53°18.92'N, 60°22.95'W) feeding on scraps of Caribou meat from a hunt the previous week. This location is approximately 195 km east of our sighting at Metchin River, three days earlier, and was possibly the same bird. We placed several large pieces of Caribou meat on the snow to feed the Ivory Gull and to encourage it to stay for further observation and photographs. At approximately 1500 hrs on 27 March 2006, an adult Glaucous Gull (*Larus hyperboreus*) joined the Ivory Gull and both fed on the Caribou meat. Both Gulls appeared to have departed on the evening of 27 March 2006 and were not observed again.

To our knowledge, our sightings are the first confirmed inland observations of Ivory Gulls recorded for insular Newfoundland or Labrador. These observations of Ivory Gulls in central Labrador may have been influenced by the recent southern extension of the winter range of the George River Caribou herd, which has occurred during the last two decades (Chubbs and Phillips 2005). Caribou from the George River herd have been recorded as far south as 52°10'N in central regions and may have facilitated the inland range expansion of other scavengers such as Coyotes (*Canis latrans*) into Labrador (Chubbs and Phillips 2005). With the Canadian Arctic breeding population of Ivory Gulls possibly in peril, and little information on their life history outside their breeding grounds, our inland observations add to the knowledge of this species' feeding habits and migration stopovers in Labrador that may provide some insight into the recent decline of this species in Canada or aid in the recovery of the population.

Acknowledgments

P. Linegar, G. J. Robertson and the late N. P. P. Simon commented on earlier drafts of the manuscript. We thank A. J. Erskine and an anonymous reviewer for their helpful comments. J. Thomas and S. Russell provided us with details of their observations. Jonathan and Kayla Chubbs correctly identified and alerted us to the presence of the Glaucous Gull. Funding for this publication was provided through the Department of Natural Resources.

Northern Goshawk, *Accipiter gentilis*, Exploits a Beagle Hound, *Canis familiaris*, as a "Beater" to Catch a Snowshoe Hare, *Lepus americanus*

JOHN T. NEVILLE

Wildlife Division, Department of Environment and Conservation, P.O. Box 2007, Corner Brook, Newfoundland and Labrador A2H 7S1 Canada

Neville, John T. 2007. Northern Goshawk, *Accipiter gentilis*, exploits a beagle hound, *Canis familiaris*, as a "beater" to catch a Snowshoe Hare, *Lepus americanus*. Canadian Field Naturalist 121(3): 329-330.

During a winter Snowshoe Hare (*Lepus americanus*) hunt with a beagle hound (*Canis familiaris*), I observed an adult Northern Goshawk (*Accipiter gentilis*) exploiting the running, barking hound as a "beater" and use strategic locations for attacks. The hawk made three attacks on a hare being pursued by the hound, and subsequently caught and killed it. To my knowledge, this report represents the first record of a Northern Goshawk using this behavior to capture prey.

Key Words: Northern Goshawk, *Accipiter gentilis*, Snowshoe Hare, *Lepus americanus*, beagle, *Canis familiaris*, beater, hunting, Newfoundland.

In eastern boreal forests, Spruce Grouse (*Dendragapus canadensis*), Ruffed Grouse (*Bonasa umbellus*), Red Squirrel (*Tamiasciurus hudsonicus*), and Snowshoe Hare (*Lepus americanus*) comprise major components of Northern Goshawk (*Accipiter gentilis*) diets (Johnsgard 1990: pages 177-182). Goshawks winter throughout their breeding range when these prey species are abundant; however Goshawks in the northern parts of their range may move further south when populations of Ruffed Grouse and especially Snowshoe Hares crash (Palmer 1988; Johnsgard 1990). In my described observation area, hares were abundant, squirrel numbers low, and both grouse species, as well as alternative prey items, very low in abundance (personal observation).

The observations described occurred in western Newfoundland (49°05'N, 57°31'W) on 4 December 2004. The area consists of approximately 70% mixed Balsam Fir (*Abies balsamea*) Black Spruce (*Picea marina*) in various-aged stands and 30% forest openings consisting of small bogs, blowdowns and alder (*Alnus* sp.) swales. Approximately 10 cm of snow had accumulated on bare ground over the previous 10 days.

During a Snowshoe Hare hunt with a beagle hound I observed unusual hunting behavior by an adult female Northern Goshawk (sex and age judged by size and plumage; Palmer 1988). The hawk exploited the running, barking dog as a "beater", and positioned itself into opportunistic attack locations where prey would likely be flushed ahead of the oncoming hound. The hawk regularly repositioned itself and selected tree-top perches (Kenward 1982) ahead of the dog in locations where it could scan the snow surface. Over approximately 20 minutes I witnessed three attacks on a hare actively pursued by my hound, the last resulting in the hare being caught and killed. With the aid of binoculars, I was able to observe the hawk's head and its fixation on snow surfaces ahead of the barking hound. I noted the hawk relocate itself 10 times during the described hunt.

The first attack occurred after the hawk had positioned itself on a tree-top perch above a 10 m-wide alder swale which offered enhanced viewing of the snow surface from above. As the barking hound progressed towards the perched hawk, the hare suddenly appeared in the alder swale and the hawk swooped down and attempted to catch it. However, dense alders hindered the bird, and the hare evaded capture. A second capture attempt occurred in similar fashion as the hare ran along the edge of a small bog. The hare re-entered dense cover before the attacking hawk approached to within about 8 m. Both of these capture attempts occurred approximately 40 m from my location. The final attack occurred roughly 60 m from my location in a 10 m by 15 m opening in the canopy. I did not see the attack but heard the hare emit a distress cry about 50 m ahead of the barking dog indicating that it had been caught. After approximately 1 minute the hound reached the attack location where its steady barking changed to intense growling indicating that the dog was then in the presence of the hawk. I advanced toward the kill site when from a distance of less than 5 m an adult Goshawk flew off the snow surface carrying an intact limp hare in its talons. The bird struggled in flight due to the mass of the hare and it was assumed that my sudden appearance had caused the bird to flee with its prey. The snow revealed indications of the attack: hare tracks, wing tip impressions, hare fur, blood and an obvious struggle site while backtracking verified that it was the hare under pursuit of my hound. Due to the quality of trailing by the hound, the hare's running ability and the apparent normal size of the hare, it is believed that it was in good condition. In addition, hares that I harvested that day and on following hunts in the same area were in excellent condition. These scenes occurred in fairly dense spruce/fir forest with the likelihood that additional attacks, without my detection, had occurred.

On 11 and 18 December 2004 during hare hunts in the described area, an adult Goshawk was observed

several times in the vicinity of the barking hound which was trailing a hare; one unsuccessful attack on a hare trailed by the hound was noted. At no time during these events did I observe the hawk attempt to strike the dog. It was also noted that Goshawks had walked along and followed hare trails on the snow surface (also cited in Palmer 1988), indicating a strong reliance upon hares in that area.

The effectiveness of exploiting beaters has been demonstrated in several species. Cattle Egrets (*Bubulcus ibis*) exploit cattle as "beaters" to flush insects and small mammals (Welty and Baptista 1988: page 422), and by doing so were more efficient than when foraging alone (Dinsmore 1973; Grubb 1976). Both Merlins (*Falco columbarius*) and Peregrine Falcons (*Falco peregrinus*) have followed Northern Harriers (*Circus cyaneus*) (Dickson 1984 in Palmer 1988); and Rough-legged Hawks (*Buteo lagopus*) have been observed following Arctic Fox (*Alopex lagopus*) to catch disturbed voles and lemmings (Welty and Baptista 1988). Reynolds (1965) suggested that beater associations may be regular, as with the Cattle Egret, or may represent an individual capacity to take advantage of a favorable situation. The latter better describes my observations, which likely originated out of curiosity as the Goshawk investigated the dog's barking and was rewarded with prey capture opportunities. As far as I can determine, this is the first report of a Northern Goshawk or any *Accipiter* sp. utilizing "beating" behavior to aid in prey capture.

Acknowledgments

I thank R. Perry and R. Otto for helpful suggestions or an earlier draft, and the helpful comments of two anonymous reviewers.

Giant Beaver, *Castoroides ohioensis*, Remains in Canada and an Overlooked Report from Ontario

C. RICHARD HARINGTON

Canadian Museum of Nature (Paleobiology), P.O. Box 3443, Station D, Ottawa, Ontario K1P 6P4 Canada

Harington, C. Richard. 2007. Giant Beaver, *Castoroides ohioensis*, remains in Canada and an overlooked report from Ontario. Canadian Field-Naturalist 121(3): 330-333.

The Giant Beaver (*Castoroides ohioensis*) was the largest ice age rodent in North America, reaching about the size of a Black Bear (*Ursus americanus*). In Canada, fossils of this species are commonly found in the Old Crow Basin, Yukon, and single specimens are known from Toronto, Ontario and Indian Island, New Brunswick. A hitherto overlooked 1891 record of a Giant Beaver skull from near Highgate, Ontario is the earliest for Canada.

Key Words: Giant Beaver, *Castoroides ohioensis*, Pleistocene, Highgate, Ontario, earliest Canadian record, paleoenvironment.

The Giant Beaver (*Castoroides ohioensis*) was the largest rodent in North America during the ice age (Quaternary – approximately the last 2 million years) (Kurtén and Anderson 1980). The great morphological similarity between Giant Beaver and modern Beaver (*Castor canadensis*) leaves no doubt that the two animals were much alike in appearance and were adapted to similar surroundings (Figure 1).

But there was one remarkable difference – size! Adults reached a length of nearly 2.5 m, the size of a Black Bear (*Ursus americanus*), and may have weighed as much as 200 kg (compared to a 1 m-long modern Beaver weighing about 30 kg) (Kurtén and Anderson 1980). However, Reynolds (2002), treating statistically a comprehensive sample, estimates Giant Beavers had a body mass of only 60 to 100 kg while assuming a length of 1.5 m [this ignores the nearly 2.5 m length of the skeleton displayed in Chicago's Field Museum of Natural History and the 2.2 m length for the Earlham College skeleton, which represents an immature individual (Barbour 1931, Figure 109)]. Using a regression she established for all rodents, Hopkins (2008) calculated a mass of 67 kg for *Castoroides*, which corresponds to Reynolds' estimate. Average weights of adult female Black Bears range from 40 to 70 kg and for adult males from 60 to 140 kg with body lengths of 1 to 2 m

FIGURE 1. Locations of Giant Beaver (*Castoroides ohioensis*) fossil sites in Canada: 1. Old Crow Basin, Yukon Territory; 2. Highgate, Ontario; 3. Toronto, Ontario; 4. Indian Island, New Brunswick. Insert shows two Giant Beavers (with fox for scale) in the foreground and Woolly Mammoths (*Mammuthus primigenius*) in the background. Reduced black and white image of a painting by George Teichmann (C.R. Harington and N. Rybczynski, scientific advisors).

(Pelton 1982), so Reynolds' estimate is still within the range for Black Bears. Other differences include a relatively narrow tail, cheek teeth with S-shaped enamel patterns on the grinding surfaces, and cutting teeth (incisors) about 15 cm long with prominently ridged outer surfaces (Harington 1996).

A primitive beaver (smaller than the modern beaver) called *Dipoides* that occupied Eurasia and North America during the late Tertiary (some 5 million years ago – indeed members of this genus occupied beaver ponds in the vicinity of Strathcona Fiord, Ellesmere Island, about 4 million years ago, Tedford and Harington (2003), and the Hand Hills, Alberta perhaps even earlier (Owen and Burns 2006) evidently gave rise to *Procastoroides*, a large beaver about two-thirds the size of the Giant Beaver. That beaver probably evolved into the Giant Beaver some 3 million years ago.

Castoroides ranged from Florida to the Yukon and from New Brunswick to Nebraska, but it has not been found outside of North America. Giant Beavers seem to have flourished in the region south of the Great Lakes toward the close of the last glaciation, about 10 000 years ago, and became extinct about that time (Harington 1996).

In Canada, Giant Beaver fossils have been found in great abundance in the Old Crow Basin of the northern Yukon (Harington 1977, 1978), and a single incisor was collected from the Don Formation in Toronto (Coleman 1933; Harington 1978) – fossils from both places probably extending back to at least last (Sangamonian) interglacial time some 130 000 years ago.

An isolated Giant Beaver incisor tooth was recovered from Indian Island, New Brunswick, near the mouth of the Bay of Fundy. It may have been deposited on a storm beach from near-shore deposits (Miller et al. 2000) (Figure 1).

It has recently come to my attention (personal communication, P. F. Karrow 2006) that a much earlier report from near Highgate, Ontario (approximately 42°30'N, 81°49'W) had been overlooked (e.g. Hay 1923; Harington 1996, 2003). J. H. Panton (Professor of Natural History and Geology, Ontario Agricultural College, Guelph, Ontario) on page 4 of an 1891 booklet titled *The Mastodon and Mammoth in Ontario*..., noted: "Associated with the remains of the [Highgate] Mastodon, a skull was found which the writer has identified to be that of an animal allied to the beaver, but this animal must have been fully six feet [about 2 m] in length, instead of two or three [about 0.61 or 0.91 m] like the Beaver of the present. One of its gnawing [incisor] teeth in the lower jaw is eight inches [20.3 cm]." I think that this description is sufficient to provide a veritable record of the Giant Beaver. Presumably this report was overlooked because of the relative rarity of Panton's (1891) published report – the only original copy known to me is in the rare book room of the Dufferin County Museum at Guelph, and because the specimen has not appeared in a major public collection. Unfortunately, I have yet to track down the actual specimen. It is not with the remains of the Highgate Mastodon (personal communication, J. Hoganson 2006).

The Highgate report is the earliest from Canada. The first recorded Giant Beaver remains were found in a peat swamp near Nashport, Ohio, and were described, but not named, by S.P. Hildreth (1837). The geologist J. W. Foster called the specimen *Castoroides ohioensis* in a publication a year later (Cahn 1932).

Giant Beavers, being well-adapted to swimming, seem to have preferred lakes and ponds bordered by swamps as their habitat because their remains have been found in ancient swamp deposits so often (Harington 1996). American Mastodons (*Mammut americanum*) evidently occupied similar habitat in open spruce forests. Indeed, at Boney Spring, Missouri, eight mastodon cheek teeth show tooth marks probably made by the lower incisors of *Castoroides* (Saunders 1977). It is worth noting that pollen analysis of sediment recovered from a hole in the sternum of the Highgate Mastodon (with which the Giant Beaver skull was associated) indicate that both mastodon and Giant Beaver occupied a boreal forest dominated by spruce probably between about 12 000 and 10 300 years ago (Hoganson 2006). Presumably this pollen analysis was carried out by McAndrews (1994, page 183) who indicates that his "recent analysis of mud" from the Highgate Mastodon shows that it belongs to pollen subzone 1b, which in his Figure 10.2 dates between about 11 800 and 10 000 BP [radiocarbon years before present (taken as 1950)].

Acknowledgments

I am indebted to the vigilance of my colleague Paul F. Karrow for noting Panton's (1891) record of the Giant Beaver skull from the vicinity of Highgate, Ontario, and thank John Hoganson for searching for the Highgate Giant Beaver skull in collections of the North Dakota Heritage Centre, Bismarck, where the Highgate Mastodon is kept. I thank two anonymous reviewers for valuable comments that helped to improve this paper.

Jacques, Christopher N., William E. Ishmael, Timothy R. Van Deelen, and Robert E. Rolley. 2007. A late born White-tailed Deer, *Odocoileus virginianus*, fawn in southcentral Wisconsin. Canadian Field-Naturalist 121(3): 333-335.

Published reports of peak breeding and parturition dates for White-tailed Deer (*Odocoileus virginianus*) indicate that deer in northern regions typically breed during November and give birth during late May and early June. However, we report a late born White-tailed Deer fawn killed by a vehicle between 12-13 March 2007 in south central Wisconsin. Morphology measurements and body weight indicated the individual was 63-76 days old, was born between 26 December 2006 and 8 January 2007, and was conceived between 14-27 June 2006. To our knowledge, this observation represents the latest documented breeding activity in northern deer populations.

Key Words: White-tailed Deer, *Odocoileus virginianus*, parturition, breeding, conception, Wisconsin.

Seasonally polyestrous breeding activities of northern White-tailed Deer (*Odocoileus virginianus*) are clearly synchronized by photoperiod (Verme and Ullrey 1984; Verme et al. 1987). However, timing of peak breeding activities and parturition can be affected by nutrition and deer herd demographics (Demarais et al. 2000). Low quality nutrition can prolong breeding and fawning activities, while high quality nutrition can shift peak breeding and fawning periods to earlier dates (Verme and Ullrey 1984).

Breeding dates vary throughout the range of the White-tailed Deer and may occur throughout the year in Central America or within short (2-3 weeks) time periods in northern deer populations (Dahlberg and Guettinger 1956; Moore and White 1971; Verme 1977; Clark 1981; Webb and Nellis 1981; Ozoga and Verme 1984). Similarly, gestation for deer varies from 196 to 213 days (Cheatum and Morton 1946; Haugen and Davenport 1950; Verme 1965, 1969), with peak parturition occurring in late May to early June in most northern deer populations (Verme et al. 1987; Brinkman 2003; Burris 2005).

Although rarely documented, occurrences of late breeding activity have been reported in northern deer populations. Throughout southcentral and northern Minnesota, previous investigations have reported conception dates in captive and free-ranging deer populations between 3 March and 9 April (Erickson 1952; Kerr and Peterson 1988; DePerno and Anderson 2000). However, we were unable to find documentation in the scientific literature of breeding activity occurring during June in northern deer populations. Our purpose was to report an occurrence of a late-born fawn and subsequent evidence of late breeding activity by White-tailed Deer in southcentral Wisconsin.

On 14 March 2007 a vehicle-killed spotted male fawn was retrieved from State Highway 23 near the village of Plain in Franklin Township, Sauk County, Wisconsin (43°16'30"N, 90°03'00"W). Because Highway 23 is frequently traveled by WEI, we are certain this fawn was killed between 12-13 March 2007. At the time of carcass retrieval, recorded body weight was 17.7 kg (39.2 lbs); however, the hindquarters were slightly scavenged. Because the amount of tissue removed by scavengers was minimal (≤ 1 kg), the estimated body weight of this fawn was 18.7 kg (41 lbs).

Normally, fawns from well-fed adult females average 3-4 kg (6.6 to 8.8 lbs) at birth (Verme and Ullrey 1984; Nelson and Woolf 1985; Verme 1989) and typically gain 0.20 to 0.24 kg (0.44 to 0.53 lbs) per day (Robbins and Moen 1975; Verme and Ullrey 1984). Thus, we assumed the fawn weighed approximately

3.5 kg (7.7 lbs) at birth and gained approximately 15.2 kg (33.5 lbs) between its birth and death. Using body measurements and estimated weight gains, we back-dated from the date of collection, suggesting the fawn was 63-76 days old and was born between 26 December 2006 and 8 January 2007. Assuming a gestation period of between 196 and 213 days (Haugen and Davenport 1950; Verme 1965, 1969), conception likely occurred between 14 and 27 June 2006. Also, physical examination indicated the fawn was in good physical condition with obvious white spotting on a relatively coarse hair coat. Admittedly, we used typical daily weight gains previously reported for fawns born during late spring or early summer (i.e., when nutritious forage is abundant) to estimate age and breeding and conception dates. Given the estimated birth date, it is possible that energy acquisition was limited and impeded growth in this individual due to reduced availability of nutritious food resources and limited milk production by the lactating mother during winter months. Consequently, breeding activity and the subsequent birth date may have occurred earlier than our estimates.

Reasons for late conception may be associated with nutritional limitations or winter weather conditions (DePerno and Anderson 2000). Although unlikely in the farmland region of southern Wisconsin, local nutritional limitations may exist. Verme (1965) noted that adult female deer on low quality diets initiated breeding activities several weeks later than individuals on higher quality diets. Van Deelen et al. (2007) reported a female deer from southern Wisconsin carrying five fetuses and McCaffery et al. (1998) noted that fetal rates among yearling and adult female deer in southern Wisconsin varied from 1.7 to 2.0 fetuses per pregnancy, indicating that high quality food resources are available throughout the farmland region of southern Wisconsin.

Late conception may be associated with mild winter weather conditions and deer breeding age. Because age of the breeding female was unknown, we were unable to determine the influence of breeding age. However, Raedeke et al. (2002) noted lower reproductive success in older-aged (i.e., ≥ 7 years of age) Elk (*Cervus elaphus*) while Rosatte and Neuhold (2006) suggested that age of a cow Elk (i.e., 11 years) may have contributed to her inability to meet annual energy requirements for normal reproduction and subsequent late conception and parturition dates during their study. Alternatively, DePerno and Anderson (2000) suggested that mild winter conditions may have extended estrous in a female deer fawn in southern Minnesota, partly explaining their observation of a late-born fawn. Verme and Ullrey (1984) suggested that yearling female deer achieved estrous later than older aged adults while Cheatum and Morton (1946) and Clark (1981) noted that fawns were bred one month later than adults. Also, female deer evidently experience recurrent estrous cycles (Plotka et al. 1977). For example, Cheatum and Morton (1946) suggested that females were capable of cycling into January, while Knox et al. (1988) reported two to seven estrous cycles in adult female deer and a potential breeding season of 172 days. It is possible that an older-aged female deer may have been unable to meet annual energy requirements for normal reproduction, which contributed to late conception and parturition observed in the present study. However, Woodford and McCaffery (2006) concluded that mild winter conditions during 2005 did not contribute to excessive mortality or depressed spring fawn production, and that deep snow conditions were limited throughout northern Wisconsin and absent by April when deer were most vulnerable to winter effects. To this end, it is also possible that a young White-tailed Deer reached sexual maturity during December 2005 and experienced multiple (6-8) estrous cycles before successfully breeding in mid to late June 2006 and consequently giving birth in late December 2006 or early January 2007.

Despite this uncertainty, we suggest that favorable winter conditions and distribution of farmlands throughout southern Wisconsin likely enable deer to maximize growth and reproductive effort at younger age classes, thus contributing to atypical breeding and parturition activities. Moreover, Rosatte and Neuhold (2006) suggested supplemental feeding may have enhanced survival of a late-born Elk calf by providing sufficient energy for the lactating cow to continue milk production during winter months. We further suggest that abundant food resources throughout the southern farmlands minimized potential growth impediments of this fawn by providing sufficient energy for the lactating mother to continue milk production during the winter season, thereby minimizing potential biases in our estimates of age, birth date, and conception dates.

Nonetheless, the sporadic observation of late-born fawns throughout the farmland regions of Wisconsin highlights the need for a greater understanding of the underlying factors that potentially contribute to late breeding activities by White-tailed Deer throughout the Midwest and Great Lakes states. It may be that by monitoring occurrence of late breeding activities that wildlife biologists may be able to identify additional factors affecting deer population dynamics.

Acknowledgments

We thank A. Kraemer and W. Wehrwein for assistance with specimen collection, and L. Ishmael for assistance with skeletal measurements. We appreciate helpful comments from T. W. Grovenburg, J. A. Jenks, K. R. McCaffery, and two anonymous reviewers on earlier drafts of our manuscript.

ZOOLOGY

Evolution and Biogeography of Australasian Vertebrates

Edited by J. R. Merrick, M. Archer, G. M. Hickey, and M. S. Y. Lee. 2006. Australian Scientific Publishing Ltd., P. O. Box 68, Oatlands, NSW 2117, Australia. xxviii + 942 pages. 230.00 AUD Cloth, 170.00 AUD. Paper.

This massive tome, covering the current state of knowledge on how and why the Australasian vertebrate fauna came to be what and where it is today, is absolutely absorbing. There is a massive amount of content, supplemented by numerous illustrations of continental movements, possible movement corridors, fossil and extant organisms, phylogenetic trees, and reconstructions of extinct organisms and ecosystems. Furthermore, much of the writing, although detailed, is in an accessible and sometimes humorous form.

The book is subdivided into 38 chapters, each written by experts on their particular subject matter. These chapters are grouped into seven broad categories, five of them covering the major traditional vertebrate taxonomic subdivisions: fishes, amphibians, reptiles, birds, and mammals. The other two subdivisions provide introductory context (an introduction to systematics, the geological history of the Australasian region, historical and current climatic influences on evolution and dispersal, and the links between the biotas of New Guinea, Indonesia, New Zealand, and Australia) and a final section entitled "Accelerated Change – the Regional Future", dealing with modern techniques in molecular systematics, tracking of marine movements of Australasian pinnipeds, and the importance of conservation planning for the preservation of the unique biota of the region. The introductory set of chapters provides critically important background information for understanding the relationships of the various land masses that make up Australasia, how these land masses were arranged within the southern supercontinent Gondwana prior to its fragmentation in the Jurassic, the influence of rising and lowering sea levels during geological history, ancient climates and glaciation, and a plethora of other environmental attributes that have been instrumental drivers in the evolution and movements of vertebrates in this part of the world.

Because the focus of the book is on evolution and dispersal, there is heavy emphasis on the fossil record and on phylogenetic reconstruction. In virtually all chapters, there is a review of the fossil record, including early hypotheses of origins of the given taxonomic group, as well as the influence of recent discoveries of fossils, as well as of modern molecular and other systematic techniques, on revising those earlier hypotheses. Thus, these chapters provide not only a summary of what is now known or hypothesized, but also a historical perspective on how the concepts developed and changed. There is interesting information in these chapters for both the specialist and the generalist, and also for those interested in the history of science. I did find the introductory chapter on systematics to be somewhat dogmatic, downplaying older approaches and advocating phylogenetic taxonomy, when I believe that most systematists now realize that even the older approaches have something to offer and their results can be integrated into the more modern approaches. Nevertheless, on balance, all of the chapters dealing with the systematics and evolution of the various vertebrate taxa are enjoyable to read and packed with information.

The authors clearly had fun writing these chapters, with many of them having a very engaging style. To give you an idea of some of the interesting chapter titles and passages in the book, here is a small sample: "Eons of Fishy Fossils" [Chapter 7], "Furry Egg-layers: Monotreme Relationships and Radiations" [Chapter 26], "Humans among Primates" [Chapter 34], referring to *Deinosuchus*, the largest crocodilian ever to exist, at 15 m in length "This generalist crocodilian could have taken on its contemporary, *Tyrannosaurus rex*, and won" [Chapter 18], referring to a fossil lizard "*Huehuecuetzpalli* ... from the early Cretaceous of Mexico, surely one of the most frightening names in all of palaeontology ..." [Chapter 19], and regarding marsupial origins "A far more complete fossil record will be required before we can confidently finger any particular taxon as the "original" marsupial. Whether North America or Asia is ultimately honoured as the marsupial "homeland", a curious twist to the story is that Gondwana, specifically Australia, might be the point of origin of placen-

tals." Scattered throughout these chapters, there also are important messages regarding conservation approaches and philosophy. In Chapter 23, dealing with island biogeography and the patterns of distribution of birds in Australasia, the author makes the point that conservation-oriented management must be directed at the entire landscape, not just the reserves. In various chapters, there are interesting thoughts on the selection of conservation reserves through the use of genetic characteristics of target populations, and the value of corridors to the movement of organisms across the landscape.

There is so much of interest and value in this book that it is difficult to summarize all of it. Suffice to say that this book contains a great deal of detail, presented in an interesting way, and that anyone interested in the evolution and biogeography of vertebrates in Australasia, or in evolution generally, will find something of value to them in this book. I recommend it highly.

A Wildlife Guide to Chile

By S. Chester. 2008. Princeton University Press 41 William Street, Princeton, New Jersey, 08540-5237 USA. 392 pages, 19.95 USD Paper.

This is a compact guide with a wide coverage. Not only does it cover birds and mammals, but includes reptiles, amphibians, butterflies, moths, marine life and flora. In addition there are descriptions of the Chilean landscape and a where-to-watch section. While it does not cover all wildlife, it does portray those you are likely to see in a typical trip. You get all this for less than 20 USD - a real bargain.

I was puzzled by the illustrations until I read they were a composite of scanned photos using Adobe Photoshop and a Cintiq monitor. The result is a photograph-like illustration arranged in the same format as a painted version. This works very well as the depictions are clear without the spurious shadows and odd shading that often plague pure photographs. This manipulation has allowed the author to show creatures at different angles, highlighting special field marks.

The sections covering birds, mammals, reptiles and amphibians follow the usual field guide format. The names are given in English, Spanish and Latin, with a listing of other names where appropriate. There follows a description of the key characteristics. This is essential as not all plumages are illustrated. So you have to read to know that a female Vermillion Flycatcher is radically different from the male. There are no range maps, but ranges are written and you need to refer to the country maps at the front of the book.

The plants are presented somewhat differently. The author has them organised into eight zones and she describes and illustrates a dozen or so key species in each zone. Some, like Opuntia, are presented at the genus level only. In total the book covers less than 100 species or about 2% of Chile's plants. For example, there are three orchids out of the fifty species listed for Chile.

Similarly, about one third of the frogs and only four snakes are illustrated. This is not as Spartan as it sounds. On a typical trip I usually see a few of the commonest species of frogs and I average seeing one snake for every 10 days in the field. Similar comments can be made about the butterflies and moths.

The author has added numerous sections on basic natural history [e.g. Life of a frog or butterfly] throughout the text. While these are informative and fun, I am not sure they should be in a guide. Typically you want to compromise between expanding coverage and reducing weight. Also they tend to be rather curt and overly definitive. For example, the short explanation on the characteristics of butterflies and moths says moths fly by night. Most, but not all do.

The regional coverage includes mainland Chile and Easter Island, Desventurades Islands, Juan Fernandez Archipelago and the Chilean Antarctic Territory. The text includes location, a little history, a physical description and coverage of the key species [especially endemics]. In particular there is a short, but interesting, coverage of Antarctica.

I believe this would be very useful as a guide in the field. The coverage is good for mammals and birds and is adequate for plants and the other animals. The illustrations show the key characteristics as well as any other method. Take, for example, the three stocky skuas, Chilean, Brown and South Polar; the text and plates do as good a job as can be expected on these difficult species. While it does not contain as many juvenile, female and flight illustrations for the small birds as Jaramillo's book [*Birds of Chile*. By A. Jamarillo. 2003. Princeton University Press, New Jersey], for the other sections it is really good. The large birds, such as albatrosses, hawks, and shorebirds are typically shown in flight. I would prefer to have depictions of, say, female siskins so I would take this and Jamarillo's book on any trip to Chile. For the Chilean Territories, however, this guide is a must.

Ecology & Evolution in the Tropics: A Herpetological Perspective

Edited by Maureen A. Donnelly, Brian I. Crother, Craig Guyer, Marvalee H. Wake, and Mary E. White. 2005. University of Chicago Press, Chicago, Illinois. x + 675 pages. 45 USD.

This volume contains most of the papers presented in a symposium held as part of the 2000 joint meeting in La Paz, Baja California, Mexico, of the three major herpetological professional groups in North America: The American Society of Ichthyologists and Herpetologists, the Society for the Study of Amphibians and Reptiles, and the Herpetologist's League. The symposium was organized as a tribute to the submission of the manuscript *The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas* (ultimately published in 2002, University of Chicago Press) by Jay Mathers Savage, and the latter's lifetime accomplishments in promoting long-term study of tropical diversity.

The contents are divided somewhat awkwardly but equally (9 chapters each) between (I) Evolution and Biogeography and (II) Ecology, Biogeography and Faunal Studies. The content is heavily weighted (13 of the 18 contributions) on tropical American species, not surprising, perhaps, considering Central and South America's richness in species and diversity. These American studies range from molecular phylogeny of caecilians, diversity of Costa Rican salamanders, an endemic Honduran frog, chromosomal variation in a group of southern Central American frogs, secondary sexual characters in tropical frogs, selection and male reproductive success in a neotropical frog, co-occurrence of hylid frogs in a temporary wetland, frog-eating anurans in the Paraguayan Chaco, biogeography of the anole genus *Norops* and of bothropoid pitvipers, and herpetofaunal analyses of the Rincon Area in Costa Rica, a Guyanan rainforest, and the Guayana highlands. The one Old World contribution is a long-term frog monitoring in Papua New Guinea, The four primarily overview contributions on a wider geographic scale are on phylogenetic taxonomy as a replacement for the Linnean system, on snake phylogeny based on Ribosomal DNA and morphology, elapid relationships, and theories of snake mimicry.

There are 27 contributors, many well known in the herpetological literature, others less so (in order of appearance): Arnold G. Kluge, Marvelee H. Wake, Gabriela Para-Olea, Judy P. Y. Sheen, David B. Wake, W. Ronald Heyer, Rafael O. de Sa, Sarah Muller, Shyh-Hwang Chen, Sharon B. Emerson, Mary E. White, Maria Kelly-Smith, Brian I. Crother, Joseph B. Slowinski, Robin Lawson, Harry W. Green, Roy W. McDiarmid, Karen R. Lips, Craig Guyer, Maureen A. Donnelly, Norman J. Scott Jr., A. Luz Acquino, David P. Bickford, Kirsten E. Nicholson, Steven D. Werman, Roy W. McDiarmid (again), Jay M. Savage, Maureen A. Donnelly (again), Magan H. Chen, Graham G. Watkins, Roy W. McDiarmid (again) and Maureen A. Donnelly (again).

This is not a comprehensive anthology of tropical diversity of amphibians and reptiles but rather selective glimpses from a random assortment of studies. Even as such it samples effectively the range of research into these in the southern climes and their importance in perspective of the variation of these groups in the world. The baseline studies presented are of particular importance in this era of unprecedented habitat destruction and climatic change after a period of relative stability against the background of well publicised observations of amphibian declines and the more poorly studied condition in reptiles.

Fossil Ecosystems of North America: A Guide to the Sites and Their Extraordinary Biotas

By John R. Nudds and Paul A. Selden. 2008. The University of Chicago Press, Chicago. 288 pages, 39 USD Paper.

Fossil Ecosystems of North America is a science book, travel guide, mystery story, and historical saga in one package — a must-read for any naturalist with an interest in fossils, evolution, and geological time. Written by paleontologists John R. Nudds, University of Manchester, and Paul A. Selden, University of Kansas, it is a North American sequel to the 2004 *Evolution of Fossil Ecosystems*, in which the authors focused on 14 renowned fossil sites around the world.

Their new book features just as many sites, all located in North America, including three Canadian locations, one site which spans the Canada-United States border, and another in the Dominican Republic. Each site is covered by one chapter, with sub-sections devoted to its evolutionary context, its discovery and subsequent research, its stratigraphic setting, biota, and paleoecolgy, and comparisons with other similar sites. An appendix, written in true travel guide fashion, provides details on exploring the fossil locations and visiting related museums.

The Canadian sites, interestingly, contain evidence of the oldest biota. They include northern Ontario's Gunflint Chert, Newfoundland's Mistaken Point, and, probably Canada's best known fossil site, the Burgess Shale in British Columbia, also a UNESCO World Heritage Site.

The Gunflint Chert in northern Ontario, discovered in 1953 by geologist Stanley Tyler, has recently been dated at a staggering 1878 million years, which places it in the Paleoproterozoic era. It helps tell the story of

life without oxygen on the planet, of a time when only bacteria lived here, in rich and unusual diversity.

The evidence of early microbial ecosystems found at the Gunflint Chert includes filamentous, spherical, and star-shaped bacteria, as well as the curious and graceful umbrella-shaped *Kakabekia* bacteria, with its spheroidal bulb, slender stipe, and umbrella-like crown. All the fossils in the book are depicted in a combination of photographs and drawings.

The fossils at Mistaken Point on Newfoundland's Avalon Peninsula were discovered in 1967 by Shiva Balak Misra, an Indian graduate student studying at Memorial University. They help fill a critical gap in the history of life on Earth: the span between the microbial ecosystems of the Precambrian era, and the animal ecosystems of the Phanerozoic.

Mistaken Point biota range from disc-like *Aspidella*, to frond-shaped *Charnia* and bush-shaped *Bradgatia*. One of the most unusual shapes is *Triforillonia*, with its three-lobed body and rounded lobes radiating from a central rosette, possibly a holdfast or polyp-like organism. The particularly rich array of fossils preserved at Mistaken Point — a census population of thousands of individuals — offers valuable snapshots of living communities at the moment they were smothered by volcanic ash.

Fossil Ecosystems of North America is a fascinating book, easy-to-read, with highly comprehensible scientific explanations, extensive details, and helpful maps, photographs and drawings. It is, essentially, a riveting mystery story about life on this planet, filled with cataclysmic events, extinctions, takeovers, and human quests for clues and explanations, often involving conflict and heated debate. At another level, *Fossil Ecosystems of North America* is a science book for students and an interested lay readership. At yet another level, it is an unusual and informative "time travel" guide. Three books in one — a valuable addition to the bookshelves of any naturalist curious about deep time.

Headless Males Make Great Lovers and Other Unusual Natural Histories

By Marty Crump. 2005. University of Chicago Press, Chicago, Illinois, USA. 199 pages. 25.00 USD Cloth, 14.00 USD Paper.

Marty [Martha] Crump, herpetologist, author of *In Search of the Golden Frog* (University of Chicago Press) and *Amphibians, Reptiles, and Their Conservation*, has compiled a remarkable collection of capsule glimpses of diverse natural history behaviour. Five section headings set the text style: Ain't Love Grand, The Mamas and the Papas, Eat to Live and Live to Eat, Don't Tread on Me, Ya Don't Say, but the serious reader should not be put off by this flippant approach — its aim is merely to grab the attention of readers who would not normally pick up a natural history book. The science is authoritative and reliable.

The detailed documentation of the scientific literature, on which the text is based, is contained in a 10-page concluding section arranged by topic with similarly innovative headings: Rampant Machismo, Come Up and See My Etchings, Sneakers and Deceivers, Survival of the Pampered, Nests Aren't Just for the Birds, Babies on Board, A Pouch Full of Miracles, Stomping for Worms, A Team Effort: How (Some) Ants Get Food, Chameleons of the Sea, Tears of Blood, Casting the Insides Outside, Spit 'n' Spray, Living Flashlights, Rapturous and Rapacious Reptiles, Smelling is Understanding, Love Potion Number Nine, It Pays to be Neighborly. This is followed by a seven-page index of organisms in the text.

This is a book ideally suited for idle moments or bedtime reading, the entries are as short and punchy as the section headings. The multitude of observations are gleaned and summarized from an amazingly vast diversity of research by ethologists and naturalists around the world. The title comes from the generally well-known mating of certain spiders where the female decapitates the male while he is still in the process of copulation. But the text covers a vast array of other behaviours, such as the stomping of Wood Turtles to bring the earthworms cherished as food to the surface. It is a remarkable testament to the seemingly endless variety of life styles and unique behavioural innovations present in the animal world, and is highly recommended to all naturalists for both education and amusement. The text is enlivened by sketches by Alan Crump.

State of North America's Birds of Prey

By Keith L. Bildstein, Jeff P. Smith, Ernesto Ruelas Inzunza, and Richard R. Veit. Nuttall Ornithological Club and The American Ornithologists' Union, Series in Ornithology (3) 2008. Softcover. 466 pages, 98 figures, 42 tables, 6-page glossary.

This is the third volume in a promising and commendable new series of ornithological publications, each appreciably larger than the AOU Monographs of long standing.

The book begins with a succinct history of raptor conservation by senior author Keith Bildstein. He tells the history of bounties as a method of raptor control. Between 1917 and 1952, Alaska paid bounties ranging from 50 cents to two dollars on over 128 000 Bald

Eagles, in spite of the bird being the American national emblem. Bounties were an expensive method of controlling predators; for example, farmers in Pennsylvania may have saved only one dollar's worth of chickens for each $1205 in bounties paid by the state.

Most members of the public viewed hawks and owls as enemies to be shot on sight. "The only good hawk is a dead hawk," people would rationalize. In Pennsylvania, so-called sportsmen thronged to specific sites along the margin of Hawk Mountain to engage in wholesale killing of most species of raptor that flew by.

Those who believe that a single person can do little to change conservation practices will be impressed by the story of Rosalie Edge, who purchased a portion of Hawk Mountain that included the shooting sites. She then hired a warden to police the land. Against intense local opposition, the land was posted and hunters were deprived of the best place in all Pennsylvania to shoot the state-bountied Northern Goshawk. Because of Rosalie's vision and determination, Hawk Mountain has become a major educational and conservation center, increasing in importance each year.

This book lists each of the growing number of raptor monitoring sites, more than one hundred, where keen volunteers flock to help. The greatest effort is given to the fall migration. The "Veracruz River of Raptors" has posted numbers as high as 5.26 million in a single fall migration. There, the top four species are the Turkey Vulture, just shy of 2 million, Broad-winged Hawk at 1.92 million, Swainson's Hawks up to 915 000 and Mississippi Kites an impressive 155 000. A million Turkey Vultures have also been counted at Kekoldi in Costa Rica.

This book is replete with maps, graphs and tables. Seven excellent maps, for example, together demonstrate the impressive band recoveries for Sharp-shinned Hawks. Movements of many other raptors, however, are less well known and knowledge of their population levels is limited.

Raptor monitoring in Canada receives appropriate attention. Since hawks only come together in increasing numbers as they move south, they do not coalesce into large flocks in some parts of Canada. An exception are the 107 000 Broad-winged Hawks counted during the 1996 fall migration at Holiday Beach near Windsor, Ontario. There are three sites in Quebec where over 1 000 of one raptor species may be counted in a single day. Ontario has ten sites, including Hawk Cliff, and there are two each in Manitoba and British Columbia. In Alberta, at Windy Point, manned since 1967, over one thousand each of Sharp-shinned Hawks and Golden Eagles may be counted passing by. At nearby Mount Lorette, the Golden Eagle count can reach the neighbourhood of 4700. Canadian contributors to the book include David Hussell, a pioneer in developing the Raptor Population Index, a new counting method that aims for more consistency in raptor counting. Erica Dunn is the lead author for the Watchsite Methods chapter.

While insect-eating and ground-nesting birds continue to decline across North America, there is more good news than bad from the raptor front. While Northern Harrier and American Kestrel are diminishing at many sites, Swainson's Hawks, Bald Eagles, Peregrine Falcons and Turkey Vultures are generally increasing. The ground-nesting harrier is at risk from many predators, but it makes less sense that the kestrel, with relatively safer nest sites in boxes and cavities, should also be in decline. The impact of habitat changes, weather and food availability is being studied for many species.

There are minor defects in this compendium. There is a misleading absence of "Diurnal" before "Birds of Prey" in the title. Owls are not included, although the four-year cyclical irruptions of the Great Gray Owl and Northern Hawk-Owl can be dramatic. We are told in one sentence that irruptive migrations of the Northern Goshawk "occur periodically in years of low prey availability" but we are not told that this is part of a general 10-year cycle involving hare, lynx and Great Horned Owls. In the section on types of migration, "irruptive migration" should have been added to "loop," "altitudinal" and "leap-frog" migrations. The book lacks a detailed index.

Despite these minor flaws, this book belongs in the library of every raptor enthusiast and in every university and college library. Some chapters warrant reading in their entirety and others are excellent reference material. Anyone with the slightest interest in the rapidly growing field of hawk monitoring should read the salient chapters, and become aware of the contents of the others.

Owls of the United States and Canada: A Complete Guide to Their Biology and Behavior

By Wayne Lynch. 2008. University of British Columbia Press, 6344 Memorial Road, Vancouver, British Columbia V6T 1Z2. 242 pages 39.95 CAD Cloth.

Wayne Lynch is an accomplished photographer and writer, I had no expectations that his newest book would represent anything less than the standard for which he is known.

The list of "things I would do differently" is quite small, but worth mentioning. The title, *A complete guide...* strikes me as being somewhat pompous... we know so much about owls that offering up a single tome as being somehow *complete* is a bit much. Then there's the tank of information yet to be discovered! Secondly, I'd be willing to bet that the vast

majority of research that was done by the original biologists was reported in metric. However, all of that was converted to imperial, rounded off and reported as such; parenthetically, the imperial values were reconverted and oft-reported as inappropriately-accurate metric values again, which muddles the original values and makes the reading stumbly. Both the birding and ornithological literature have long used a convention of capitalizing bird names; this avoids some potential confusion when, for instance, referring to "the Northern Hawk Owl" (the species) versus "the northern hawk owl" (the hawk owl found more northerly than others). I find newspapers reticent to adopt this standard, but there's no reason for this book to have done so. Those well-read in bird literature will do mental hiccups frequently while reading this book.

Chapters often start with a journal entry or description of an individual encounter with owls that beautifully sets up the chapter's theme. By doing this, Lynch maintains a personal connection with readers, which then encourages them to continue reading the more-matter-of-fact, but still very well-written material later.

There is a nice 10-page identification guide to the owls, with range maps and a synopsis of information such as habitat preferences, life span, diet and status. Although the text is good, the maps are deceptive. Unlike most field guides, the maps here use only one colour to report the species' ranges. And if you didn't know any better, you'd think the Snowy Owl bred everywhere in Canada, and into the northern tier of the United States (which it doesn't). Johnsgard's book on North American Owls does more justice to the ranges.

The rest of the book is written topic-by-topic, much like Duncan's *Owls of the World*. Other owl books, like Mikkola's *Owls of Europe*, take a more species-by-species account, with a few introductory chapters on topics like food, anatomy, movements, etc. I don't think one format can be said to be better than the other in general, each excels for different reasons. The approach adopted by Lynch makes for a more coffee-table friendly book; different species can be depicted in any one chapter, making comparisons among, for instance, insectivores to carnivores, readily apparent.

Throughout the book are sidebars containing synopses of topics related to the chapters' contents. I've always liked this approach as it allows for information that is otherwise not readily incorporable to be presented. In this book, the topics range from the pH scale (used to discuss digestion) to brooding behaviour.

Finally...the photographs. Dr. Lynch is perhaps best-known for his stunning photography. There are some awe-inspiring habitat shots, and double-page spreads that leave the reader with a sense that "I must visit that place." The shots of the owls themselves rate with the best I've ever seen and include depictions of some behaviours that are not frequently seen. Not to diminish the writing at all, but the photographs really make this book what it is.

Owls of North America

By Frances Backhouse. 2008. Firefly Books Ltd, 66 Leek Crescent, Richmond Hill Ontario L4B 1H1. 215 pages, 34.95 CAD Cloth.

Owls of North America, by Canadian writer Frances Backhouse, is a beautiful book — literally. The first thing I did when it came into my possession was to look at the photographs. A Great Horned Owl silhouetted against a sunset. A close-up of the same species' primary flight feathers. An Elf Owl delivering a cricket to its cactus nest. The large eyespots on the back of a Northern Pygmy-Owl's head. Great Gray Owls engaging in mutual preening. A young Long-eared Owl hanging upside down from a twig. A Short-Eared Owl stretching its leg as a warm-up to hunting.

I would have been thrilled with the book for the photographs alone. When I started reading, it got even better. Eight chapters discuss topics covering a wide range: owl and human relations, owl family groupings, life trajectories, feeding habits, communication, adaptations for nocturnal life, and more. Almost 80 pages are devoted to relatively comprehensive species profiles that provide photographs, maps, and details on appearance, voice, activity, roosting, distribution, habitat, feeding, breeding, migration, and conservation. A glossary and bibliography complete the information offerings.

The book brought alive owl species I was only vaguely aware of. The Elf Owl of the southwest, the world's smallest owl, which feeds mainly on insects. The Flammulated Owl of the west, also an insect-eater, with ventriloqual abilities that make singers difficult to locate. The Vermiculated Screech-Owl of Mexico, Central and South America, which sings like a toad.

The book also deepened my understanding of owls which are more familiar to me. The Great Horned Owl, that consumes a greater diversity of prey — from grasshoppers to great blue herons — than any other North American owl. The Great Gray Owl, which is benefiting from nesting platforms; one study revealed that nesting success was higher on platforms than natural nest sites.

The Eastern Screech Owl which, in Texas, brings live Texas blind snakes to its nest to eat the soft-bodied larvae of insects attracted to pellets, fecal matter, uneaten food, and occasional dead nestling accumulated in the cavity. The Burrowing Owl, which produces a sound remarkably like a rattlesnake's rattling buzz — a sound that may have evolved to deter predators such as badgers and weasels from entering nest holes. It has also, the author writes with a twist of humour, "definitely proven effective on occasion in discouraging ornithologists from reaching blindly into burrows."

Owls, the book clearly communicates, are fascinating earth residents with unique skills and adaptations that equip them for important ecological roles. As such, they deserve admiration, respect, and help in reversing the habitat loss from which virtually all owl species suffer.

The Tree of Life: A Phylogenetic Classification

By Guillaume Lecointre and Herve Le Guyader. 2006. The Belknap Press of Harvard University Press, Cambridge, Massachusetts. 560 pages. 39.95.USD.

Here is a textbook to usher in the 21st Century based on the use of cladistics and the steadily increasing data from molecular biology. These have been gradually changing systematic biology over the past 30 years. It may not be the last word in this dynamic field but it certainly is in the current mainstream. It presents a genealogical approach to classification of the diversity of all life on earth through the phylogenetic analysis increasingly promoted by many researchers as the successor to the Linnean System. The latter was outlined for plants in 1735 and for all organisms in 1758 and thereafter long universally adopted and taught throughout the world. The Linnean system accepted the concepts of its time — divine creation and the Great Chain of Being, each individually created group of organisms, from single celled to human, conceived of as progressively "higher" with *Homo sapiens* as the culmination. After a hundred years, in 1858, Charles Darwin outlined descent with modification by natural selection which showed how evolution could occur. Shortly after, in 1866, Ernst Haeckel coined the term phylogeny but it was nearly a hundred years later before Willi Hennig outlined the comprehensive application of an objective cladistics approach (phylogenetic systematics) published in German in 1950 and in English in 1966.

The Tree of Life outlines major groupings for the present estimated 1 749 577 described and currently recognized organisms. After a preface and introduction there are 15 chapters. The initial one on "Life" is followed by Eubacteria, Archaea, Eukaryotes, Chlorobionta, Embryophyta, Metazoa, Protostomia, Mollusca, Eurarthopoda, Deuterostomia, Sarcopterygii, Mammalia, Primates, Actinopterygii. Some group names are familiar from traditional classifications, some will be new and strange to most naturalists. Abolished are familiar classification categories (Kingdom, Class, Order, Family) to be replaced by diagrams (dendrograms) depicting relationships. Also vanished are what are now regarded as mixed groupings such as reptiles and fish.

Each chapter is subdivided and a chart presented of the relationships of the included forms discussed. Each grouping has line drawings of example organisms and features, a brief general description of included forms and sections on ecology, some unique derived features, and examples of included forms. A sidebar gives number of species, oldest known fossils, and current distribution.

The book concludes with 13 Appendices of "trees" showing the cladistic view of relatedness, and including "Where are they" giving the new positions of major traditional groups of both one-celled and multicelled life, Sequenced Genomes (listing organisms for which the genome is entirely sequenced or almost so as of January 2006), a one-page General Bibliography, a Glossary of 70 entries from Alignment to UPGMA (Unweighted Pair Group Method Using Arithmetic Average), Index of Common Names and Index of Latin Names.

The intent of the volume is to move this phylogenetic approach to classification out of its currently restricted academic position and bring it into the mainstream to replace the traditional teaching now rendered archaic, at least in the view of the presenters. The authors are well suited to the task, throughly immersed in the modern concepts and teaching. Lecointre is Professor and Research Scientist at the Museum National d'Histoire Naturelle and Le Guyader is Professor of Evolutionary Biology at the University of Pierre and Marie Curie, both in Paris, France. The book was originally published as *Classification phylogenetique du vivant* (third edition, Editions Belin, Paris, 2006) and translated by Karen McCoy. It is illustrated by Dominique Visset.

FRANCIS R. COOK

Emeritus Curator and Researcher, Canadian Museum of Nature, P.O. Box 3443, Station D, Ottawa, Ontario K1P 6P4 Canada

Biology of the Snapping Turtle (*Chelydra serpentina*)

Edited by A. C. Steyermark, M. S. Finkler, and R. J. Brooks. 2008. The Johns Hopkins University Press, 2715 North Charles Street, Baltimore, Maryland 21218-4363. x + 225 pages 75 USD.

The *Biology of the Snapping Turtle* consists of 17 review papers on various aspects of the life history of one of the most recognizable turtles of North America. Part 1, Taxonomy and Systematics, consists of four chapters covering the systematics of the family Chelydridae, the fossil history of the family, the anatomy of the skull, and molecular insights into the systematics of the family. Part 2, Physiology, Energetics, and Growth, consists of seven chapters covering such disparate topics as respiration, reproductive physiology, thermal ecology, energetics, embryology, overwintering adaptations and growth patterns. The final section of the book, Life History and Ecology, consists of six chapters on nesting ecology, water relations of the eggs, sex determination, physiology of hatchlings, population biology and geographic variation in life history traits.

Although many of the chapters are strictly review papers, a number of the authors have included previously unpublished data from their own work or the work of others. For example, H. Bradley Shaffer and his co-authors include their analysis of the genetic variation across the currently recognized four subspecies of Snapping Turtle. Their results are consistent with earlier less extensive work: first of all, there is no molecular evidence to support the recognition of the Florida Snapping Turtle *C. s. osceola*) as a distinct taxa; second of all, the Central American Snapping Turtle *C. s. rossignonii*) and the South American Snapping Turtle *C. s. acutirostris*) both appear to be separate evolutionary lineages and should be viewed as separate species.

While many of the papers in this volume are tightly focussed on the Snapping Turtle, a number of the papers could just as easily have appeared in a volume on the biology of turtles in general. For example, Gordon Ultsch and Scott Reese's paper on overwintering is a thorough review of the literature on turtle physiology with regards to hibernation.

Overall, the quality of the papers is high. One of the highlights of the book is the chapter on nesting ecology written by researchers involved in three long-term studies of Snapping Turtles at Algonquin Park, Ontario; the Edwin S. George Reserve, Michigan; and the Savannah River Site, North Carolina. There are also a few careless mistakes in the book that more careful editing could have caught. The Wood Turtle (*Glyptemys insculpta*) and the Bog Turtle (*G. muhlenbergii*) are still placed in the genus *Clemmys* in the text and in the index. There is also more overlap in material than is required. Growth of the embryo is discussed in both the chapter on the embryo and the chapter on growth. The relationship between clutch size and body size is thoroughly charted in the chapter on nesting ecology, discussed in the chapter on population biology and re-visited in the chapter on geographic variation. The editors are also strangely silent. There is no introduction from them explaining the origin or rationale for the volume or any kind of concluding chapter synthesizing the themes of the volume. Nonetheless, anyone with a technical interest in the biology of turtles (not just Snapping Turtles) will find this an extremely valuable reference work.

DAVID SEBURN

Seburn Ecological Services, 2710 Clarenda Street, Ottawa, Ontario K2B 7S5 Canada

Wildlife of North America: A Naturalist's Lifelist

By Whit Bronaugh. 2006. University Press of Florida, Gainesville, Florida, USA. 565 pages. 29.95 USD.

This is a bold and daring compilation that few would have the courage to undertake and present. It is a contribution to the attempt to promote systematic record keeping by the vast number of casual or non-academic naturalists. The volume is essentially a checklist of all native and introduced mammals, birds, reptiles, amphibians, freshwater fishes, butterflies, dragonflies and damselflies recorded to date for North America. These groups include relatively large and often conspicuous animals for which a naturalist can identify a significant number of species on sight.

It is based on the latest (at the time of publication) authoritative listing for each group with the full realization that work is ongoing for all group names and species recognition is constantly changing with each new study that produces new knowledge that necessitates revisions. Despite this, probably enough stability has been reached in each included group that names used here will still be able to at least be equated with those that will be current in another decade or two hence.

The contents include a Preface (the author's purpose and how he came to compile the book and his acknowledgments), a Checklist of North American Orders and Families for the included groups, A List of Symbols (indicating species extinct and since when), an Introduction to the main text, How to Use this Book, Biodiversity and Zoogeography of North America (with maps of number of species in each province and state) and Extinct Species. The bulk of the book follows (pages 83 to 430) listing English and scientific name for each species by family and blank spaces for user remarks such as first observation date, place or other data considered relevant. The

are additional blank entry spaces at the end of each group section for addition of species defined after the publication of this book. The book concludes with an Appendix of recent taxonomic and nomenclatural changes which depart from standard field guides (pages 431-478), Works Cited (pages 469-478), Index to Scientific Names (479-528), and Index to Common Names (pages 529-565). The last two are particularly valuable for equating a name used in older field guides to the name recognized currently.

What this is not is a field book. It is far too large and bulky to be carried on outings. It is a book for post-expedition entries. It is devoid of keys or text on identifications, these are left to consultation of the many guides listed in the references. But even naturalists who may purchase the book with the best of, but later unrealised, intentions, will find it a valued quick reference for their library for its analysis of North America distribution patterns, comparative species totals, and post-Pleistocene zoogeography, among many other considerations, all carefully compiled from recent authoritative sources.

Whit Bronaugh now lives in Oregon and makes a living as a nature writer and photographer, but he grew up among the carefully manicured horse farms of central Kentucky and did not really discover nature until a university field course in Africa. He has remained in awe of the diversity of animal life ever since and, as an initial lifelist of birds expanded to include other groups, the concept to this book was generated initially to fill his own needs. His other work has appeared in popular periodicals such as *Wildlife Conservation*, *National Geographic*, *Natural History*, and *Smithsonian*. His photography presented here is restricted to a few small black-and-white reproductions in the book itself and colour ones on the attractive dust jacket.

FRANCIS R. COOK

Emeritus Curator and Researcher, Canadian Museum of Nature, P.O. Box 3443, Station D, Ottawa, Ontario K1P 6P4 Canada

BOTANY

Grasses of Colorado

By Robert B. Shaw. 2008. University Press of Colorado, 5589 Arapahoe Avenue, Suite 206C, Boulder, Colorado 80303 USA. *xi* + 647 pages. 75 USD Cloth.

The grasses constitute one of the most important families of flowering plants in the world, both economically and ecologically. They are extremely diverse and generally comprise about one-tenth of the vascular flora in many parts of North America. They are dominant in many ecosystems, including several of the most extensive ecosystems in Colorado. *Grasses of Colorado* provides a thorough, up-to-date treatment of the 335 species of grasses known to occur outside of cultivation in the state. The book is arranged in several sections. The introductory section deals mostly with utilitarian aspects of grasses, including food and forage, soil conservation, turf and ornamental uses, and harmful grasses. The ecological significance of grasses receives rather limited discussion, despite the prominent role of the family in the state's major ecosystems. Following the introduction is a section on the physiography and ecoregions of Colorado which is informative and useful in understanding the distribution patterns of the grasses in the state. Maps outlining the major landforms, river systems, mountain ranges, and ecological subdivisions assist considerably in understanding these patterns. This section is followed by a chapter on grass morphology which contains good illustrations that cover most of the important features that are used in grass identification. These illustrations are particularly helpful when coupled with the illustrations of each species that are interspersed in the main taxonomic, descriptive part of the book.

The bulk of the book is comprised of the taxonomic treatments, including keys, descriptions of subfamilies, tribes, genera, and species, illustrations, and range maps depicting counties of occurrence. The species descriptions are quite detailed, including the important floral and vegetative characteristics. A concerted effort has been made to ensure that all descriptions are parallel, not just between species within a genus, but across all genera. Each species treatment also contains information on major synonyms, common names, origin (native vs. alien), a general habitat description, and a section for comments on status in the state, taxonomic issues, and similar species. The accompanying illustrations are reproduced with permission from the two grass volumes of the *Flora of North America* (Barkworth et al. 2003, 2007). These generally are excellent and, when used in conjunction with the keys and descriptions, should enable successful identification. On occasion, I found the comment subsection in the species treatments to be redundant (same information repeated for several species within a genus), but more often than not, there was useful supplementary information there.

In general, Shaw follows the taxonomic concepts espoused by other grass experts, as reflected in the *Flora of North America*. However, there are a few departures, such as the segregation of *Melica* into two genera, *Melica* and *Bromelica*, the segregation of *Bromus* into four genera, *Anisantha*, *Bromopsis*, *Bromus*, and *Ceratochloa*, corresponding to the sections of *Bromus* in most other North American treatments, and the separation of *Critesion* from *Hordeum*. Most of the rest of the taxonomic treatment will be familiar

to those who follow grass taxonomy, including the segregations and realignments of species within genera in the tribe Stipeae.

The content of the book generally is of high quality, and, as much as is possible with a group of plants that has its own set of descriptive terminology, the text and keys are readable with jargon minimized. There are occasional inconsistencies in the text; for example, in the treatment of *Digitaria sanguinalis*, under Origin, the species is said to be native, but in the Comments section, it is stated to be "a European species now established as a global weed." I detected relatively few proof-reading errors (e.g., synonym not italicized, punctuation misplaced, rare spelling errors), and these do not detract substantively from the book.

This book provides a welcome updated treatment of the grasses of Colorado. In spite of the fact that there is a recent North American taxonomic treatment of the family, there will always be a need for regional and local treatments, especially for large and diverse families such as this. The book should prove to be useful for the identification of grasses in several adjacent states, including much of the upper Midwest, from Montana to North Dakota and south to Kansas. It should also be useful in the southern portions of the Prairie Provinces.

WILLIAM J. CRINS

Ontario Ministry of Natural Resources, Ontario Parks, 300 Water St., Peterborough, Ontario K9J 8M5 Canada

The Macrolichens of New England

By James W. Hinds and Patricia L. Hinds. 2007. Memoirs of the New York Botanical Garden Volume 96. New York Botanical Garden Press, Bronx, New York. 608 pages, 65.00 USD Cloth.

The most recent publication on lichens from the New York Botanical Garden is the first detailed treatment of New England macrolichens. Before the reader even opens *The Macrolichens of New England* the 14 beautiful photos on the front and back covers give the sense that it is something special. This much-awaited guide, drawing on 35 years of collected photos and knowledge of the lichenologist team of James and Patricia Hinds, describes and illustrates the lichen flora from a very unique region rich in lichen flora. The Hinds share with the reader a plethora of information ranging from specific species treatments to general lichen biology so it appeals to the serious professional and novice alike.

A quick key index inside the front cover provides the reader with direct access to a group or classification of their choice; a useful tool allowing this book to be used strictly as a field guide. The front sections should not to be overlooked as they provide, in much the same way as I. M. Brodo, S. D. Sharnoff, and S. Sharnoff (2001) *Lichens of North America*, 70 pages of useful information that will inform and help the reader to explore the world of lichenology. These early chapters provide essays on anatomy, ecology, lichen conservation and population trends, and identification. The general key section follows the background (approximately 30 pages) which will direct you into the genus descriptions (some 400 pages). The extensive references cited, glossary, two appendixes, and index, organized by Latin name, round out the book.

A total of 502 species is covered, including 308 with colour photos. Some of these species are extremely rare, not typically described in literature of this type. Included are species found in adjacent localities, which could occur in the region of study. Microlichens are briefly discussed in the introductory chapters but are not treated with the same detail as the macrolichens. Many of the species discussed have coastal affinities, with many others found inland, making this book a great resource for readers interested in species across the entire continent.

For the most part the photos are stunning, and beautiful, capturing key identification features needed for the reader to compare species observed or collected with the photos in the book and make accurate and correct identifications. Capturing the entire depth of field in macro photography is a common problem and generally the authors do a great job. Some of the images, however, suffer from poor depth of field sharpness and have blurred or fuzzy portions. (i.e., figures 111, 165, 272). There are many more stunning and beautiful images with great depth of field than with out. Species described without an image include a reference, when available, to another source where a photo was provided.

Two omissions of occurrence records should be noted. One was on page 51. When describing the rarity of *Leptogium rivulare* the authors suggest that the most recently known collections occurred in the early 1970s (Southern Ontario); however, collections of this species occurred in the early 2000s (Southern Ontario 2002 and Manitoba in 2003) and more recently in Southern Ontario in 2007 (not published). The second was a reference to the distribution of *Xanthoria parietina*, page 525, which is described as restricted to oceanic coastal areas. In general this is true but recent inland discoveries, including records in Southern Ontario (2002 and 2006); have been documented.

Using photographs only for identification can result in a misidentified specimen. In *The Macrolichens of New England* the blend of text and images will enable the user to avoid this error. There are incredible photos of very rare lichens not typically seen by the average lichenologist. The paired photo examples of various species showing the upper and lower surface (*Peltigera* sp.), wet thallus versus dry thallus (i.e., *Placidium arboretum*, *Physconia detersa*, and *Pyxine sorediata*), and macro versus micro features (i.e., *Leptogium*, *Sterocaulon, Usnea*) make this book incredibly valuable because some of these species can only be separated by comparing these features.

The book is 7 ½ inches wide 10 ¼ inches long and 1 ⅛ inches deep. It weighs approximately 2.0 kg. Although the book is by no means light, it is a more manageable field guide than Brodo et al, which is roughly twice the size and weight, making this book a more welcome field companion. I have toted both into backwoods locations and appreciated the size and weight difference. It has a hard durable cover with a small ruler drawn on the last page that could be used for field measurements. If taken into the field, however, the glossy covers will inevitably get scratched as there is no slip cover to protect it.

The authors tout this book as the "the most comprehensive work of its kind" and they deliver. This book, like Brodo et al., will be an instant classic. Those who read this book will have no choice but to be drawn into the world of these fascinating organisms.

Wild Plants of Eastern Canada

By Marilyn Walker. 2008. Nimbus Publishing Ltd., P.O. Box 9166, Halifax, Nova Scotia B3K 5M8. 202 pages, 24.95 CAD.

Wild Plants of Eastern Canada was not what I expected. I was looking forward to another wild plant field guide, a cross-referencing source, a book offering additional details and visuals to aid in identifying those hard-to-pin-down native asters and goldenrods. That's not what *Wild Plants of Eastern Canada* is about.

My first reaction to the book was, consequently, mild annoyance – which developed into growing curiosity, then pleasant surprise the further I read. *Wild Plants of Eastern Canada* turns out to be more than a wild plant identification guide. Divided into three parts – (1) "Plants and People of the Northeast", (2) "Field Guide", (3) "Recipes" – the book is a human and natural history, an identification tool (of sorts), and a recipe book.

Part 2, the "Field Guide", takes up the most pages. It contains extensive information on each plant profiled, including scientific and "other" names, general information about the plant family, habitat details, a physical description of the plant, and, depending on the species, sections on usable parts, common uses, medicinal properties, and garden-related particulars. The accompanying black-and-white photographs are helpful, while the leaf prints add a subtle artistic touch.

The recipes covering almost 40 pages in Part 3 of *Wild Plants of Eastern Canada* are intriguing. They range from "classics" such as teas and bannock, to preparations using petals, buds, roots, and berries. I have not yet had the opportunity to test any of them, but I am looking forward to trying out goldenrod crepes, dandelion leaf sandwiches, and clover butter.

Part 1 of the book I found the most interesting and most trying. It was there, not far into the section, that I discovered the book's most frustrating limitation: its geographical scope. I had assumed the "Eastern Canada" part of the book's title to refer to the usual territory stretching from the Atlantic Ocean to the western end of Ontario. Yet *Wild Plants of Eastern Canada* ends up covering the Maritime provinces only — not a bad thing if that is what the reader is expecting. But as a Quebec resident, I was hoping my region was included in the book.

The rest of the information in Part 1 comes as a pleasant surprise. Rich in historical and anthropological detail, it provides a succinct and comprehensive overview of Atlantic Canada's paleoenvironment, European settlement, and Aboriginal history and culture, including First Nations traditional plant knowledge.

I found the first sub-section, "Like Plants, Like People" the most intriguing. There, the author writes: "Like people, plants are great colonizers. They wander about, singly or in "herds", trying out new conditions until they find somewhere to settle in. If the environment is not suitable, they go elsewhere out of necessity, or perhaps out of the same sense of adventure that inspired human migration" — an intriguing, and for me appealing, perspective.

My main gripe with the book is its main title. *Wild Plants of Eastern Canada* is misleading, and the extra text on the front and back covers does not provide any clues regarding the geographical scope of the book. Yet for individuals able to get their hands on it, the smaller typeface on the front cover — "Identifying, Harvesting and Using", "Includes recipes & medicinal uses" — provides helpful hints regarding the book's content.

Wild Plants of Eastern Canada is a welcome addition to the wild plants section of my bookshelves, despite its limitations and frustrations.

Sods, Soil, and Spades: The Acadians at Grand Pre and their Dykeland Legacy

By J. Sherman Bleakney. 2005. McGill-Queens Press, Montreal, Quebec, and Kingston, Ontario. *xxxii* + 221 pages. 14.95 CAD.

Sherman Bleakney is widely known in Canada as a zoologist of remarkeably diverse interests and publications. As curator of amphibians, reptiles and fish at the National Museum of Canada from 1952 to 1958 his expeditions from the Maritimes to Alberta doubled the national herpetology collection to 14 000 specimens. He published a ground-breaking analysis of the distribution of amphibians and reptiles in Eastern Canada (Bleakney 1958) based on his 1956 Ph.D. thesis from McGill University supervised by legendary Max Dunbar, the first Ph.D. in herpetology at a Canadian university (Cook 2007). In 1958 he returned to Nova Scotia where he had been raised, and to Acadia University where he had obtained his B.S.c and M.Sc., to teach zoology and where he has remained until and past retirement. Although initially his herpetological contributions continued there, particularly on both freshwater and marine turtles, he became increasingly immersed in publishing on fishes and invertebrates of the marine ecosytem of the Minas Basin, culminating in a book on nudibranchs (Bleakney 1996).

Since 1994 he has further broadened his environmental perspective and turned his critical trained eye and literary skills and enthusium to the dykes originally built by the French settlers (Acadians) along the Minas Basin at the head of the Bay of Fundy in Nova Scotia. The result is a fascinatingly detailed and throughly documented history and construction analysis, with sections on the geology, post-glacial events, and fauna of an area which boasts the world's highest tides and the land reclaimed and protected from them. For this he has been able to draw on written and oral accounts and has paid particular tribute not only to the builders but also to those who left an accurate record of techniques of dyking brought from the low countries of Europe and adapted to the local conditions.

Alliance of Natural History Museums of Canada Annual Meeting and Awards

On 24 and 25 September 2007 the Alliance of Natural History Museums held its annual meeting in Ottawa. The ANNHMC is a network of Natural History Museums created in 2003 to enhance collaborative work in the areas of research, collections development, and education about the natural environment. The 12 founding members (from west to east) are the Royal British Columbia Museum, Royal Alberta Museum, Royal Tyrell Museum of Palaeontology, Royal Saskatchewan Museum, Manitoba Museum, Canadian Museum of Nature, Montreal's Nature Museums (Biodome, Insectarium, Botanical Gardens and Planetarium), New Brunswick Museum, Nova Scotia Museum of Natural History, and the Rooms, Newfoundland and Labrador. The Royal Ontrario Museum joined in the summer of 2007.

"By sharing knowledge and resources among member museums, we can impove our efforts in opening up the world of Canada's rich natural history to Canadians and educating them about important environmental issues" explained Johanne Landry, President of the ANHMc and Director of the Insectarium (part of Montreal Nature Museums). We have a stragegic plan in place and have completed a survey of our combined collections. This meeting was an important opportunity for our representatives coast to coast to come together and identify our next steps." Together, the member museums safeguard more than 19 million catalogued specimens of plants, animals, minerals and fossils collected over 150 years that are the record of Canada's natural history through time.

At a reception 25 September on Parliament Hill in Ottawa the Alliance welcomed the Royal Ontario Musuem as a new member and presented a new award, the Gold Leaf Award for significant contribution to the study of natural history in Canada to Dr. Francis R. Cook, researcher emeritus at the Canadian Museum of Nature and editor of the Canadian Field-Naturalist, and posthuously to the late Dr. Bruce Naylor, former director of the Royal Tyrell Museum of Paleontology and founding ANHMC president. The award has been renamed for Dr. Naylor.

Minutes of the 128th Annual Business Meeting of The Ottawa Field-Naturalists' Club 9 January 2007

Place and time: Canadian Museum of Nature, Ottawa, Ontario, 7:30 pm
Chairperson: Mike Murphy, President
Attendance: Twenty-six persons attended the meeting.

Attendees spent the first half-hour reviewing the minutes of the previous meeting, the Treasurer's report and the Report of Council. The meeting was called to order at 7:35 pm with some opening remarks from the President.

1. Minutes of the Previous Meeting

1. Under Report of the Nominating Committee; D. Kitching should be listed under "Members at Large"
2. Under Presentation of Awards for the 2005 OFNC Photo Contest, "The Grand Prize winner received a digital camera and photo printer donated by Galaxy Camera"
3. Grand Prize winner: Dave Sangster

It was moved by Henry Steger and seconded by Ann MacKenzie that the minutes be accepted.

(Motion Carried)

2. Business Arising from the Minutes

There was no business arising from the Minutes.

3. Communications Relating to the Annual Business Meeting

There were no communications relating to the Annual Business Meeting.

4. Treasurer's Report Frank Pope

Frank Pope reviewed the financial report for the year ending 30 September 2006, noting that the Club's net assets have increased by approximately $2000. Listed under "Other revenue" was the balance of a bequest from the estate of Mildred Groh ($23 717).

Frank answered questions from the audience with regards to the increased publishing costs of the CFN. He explained that this was due to the publishing of 4 issues in 2006 versus the 2 issues published in 2005. Several audience members spoke about electronic publishing as being the way of the future for scientific journals, and one which the CFN should actively consider.

Moved by Frank Pope and seconded by Ken Allison that the Financial Report be accepted as amended.

(Motion Carried)

5. Committee Reports

Mike Murphy asked for questions and comments on the Committee reports which had been distributed to the attendees. He thanked the committee chairs and committee members for their work over the past year.

Moved by Gillian Marston and seconded by Diane Lepage, that the reports be accepted.

(Motion Carried)

6. Nomination of the Auditor

Moved by Frank Pope and seconded by Ann MacKenzie, that Janet Gehr continue as Auditor for another year.

(Motion Carried)

7. Report of the Nominating Committee Eleanor Zurbrigg for Fenja Brodo

President	Mike Murphy
Vice President	Ken Allison
Secretary	Susan Laurie-Bourque
Treasurer	Frank Pope
Past President	Gary McNulty
Business Manager	Bill Cody
Editor CFN	Francis Cook
Editor T&L	Karen McLachlan-Hamilton

Committee Chairs

Birds	Chris Traynor
Computers	Dan Millar
Conservation	Stan Rosenbaum
E&P	Gillian Marston
E&L	Fenja Brodo
Finance	Ann MacKenzie
FWG	David Hobden
Membership	Henry Steger
Publications	Ron Bedford
ON Rep	Eleanor Zurbrigg

Members at large

Julia Cipriani
Diane Kitching
Annie Belair
Diane Lepage

Chairs not on Council

Awards	Ernie Brodo
Macoun	Rob Lee
Nominations	Fenja Brodo

Retiring from the council: Susan Howell, Justin Peter

New on the council: Annie Belair

Moved by Eleanor Zurbrigg and seconded by Frank Pope, that the slate of nominations for the 2007 Council be accepted.

(Motion Carried)

8. New Business

There was no new business.

There was a comment from a Club member on the need to involve the younger generation of Club members in Club activities. Ways of bringing these members together at the monthly Club meetings such as the use of name tags and formal introductions were discussed.

9. The OFNC Website; a virtual tour by our Webmaster Sandra Garland

The OFNC has a wonderful, informative website maintained by Sandra Garland. Sandra gave us a tour of the Website with aid of a laptop and digital projector. She informed us that the website was started 10 years ago by the E&P committee. Since then the site has grown to become the information rich resource for Club members and the public at large that it is today. Web statistics reveal that the site is actively used and accessed regularly.

Mike Murphy thanked Sandra for her excellent work and for her entertaining and informative presentation.

10. Adjournment

Moved by David Hobden and seconded by Diane Lepage that the meeting be adjourned at 9:35 pm.

(Motion Carried)

SUSAN LAURIE-BOURQUE
Recording Secretary

The Ottawa Field-Naturalists' Club Committee Reports for 2006

Birds Committee

The Birds Committee, in conjunction with the Club des Ornithologues de l'Outaouais, compiled the 2005 Christmas Bird Count. The fall bird count was held in October 2006 and was a successful event. This year marked the 10th anniversary of the Peregrine Falcon Watch. Commemorative hats were produced to mark the occasion. One male was successfully fledged. The Bird Records Sub-committee continues to review records of rare birds and has made Rare Bird Report forms available on the Club's web site. This year's Seed-a-Thon was successful in raising over $600.00 for Club feeders. A new feeder was built for the OFNC by the National Capital Commission and was installed at the Mer Bleu. The Committee continues to operate the Ottawa Bird Status Line and the Rare Bird Alert.

CHRIS TRAYNOR
Chair, Birds Committee

OFNC Computer Management Committee

The Computer Management Committee did not meet during 2006.

MICHAEL MURPHY
OFNC President

Education and Publicity

Kiosks, Displays and Other Events

The committee created another set of display panels for the large display using the Watershed as the theme. Committee members participated with displays at the Ottawa-Carleton Elementary Teachers' Federation Publishers' Display, National Wildlife Week's Wildlife Festival, several Environment Week events (National Resources Canada, Agriculture and Agri-food Canada, Citizenship & Immigration and National Defense), the Sierra Club 'People & the Planet' conference, and the OFNC Soiree.

Once again the OFNC participated in the Ottawa Science Fair sponsoring 3 prizes for projects co-judged by Jeff Sleevington and Ed & Pub committee member Kathy Conlan.

The committee also arranged speakers for outside groups. Several digital photo presentations were also made by committee members.

OFNC Membership Drive

The portable kiosks were used for approximately 8 outings for a successful fall club membership drive.

Digital Library

The committee continued to enhance the OFNC's 'digital photo library and catalogue' scanning many of the slides from the slide library.

OFNC Nature Photography Contest

The Committee initiated a 2nd Annual Photography Contest (to run until September 2007) to encourage discovery of nature and further enhance the club's digital library. This contest is open to the general public.

Brochures

The committee continued to distribute the club brochure to area libraries and nature shops.

Club T-Shirt

Committee member Laura Penney designed a beautiful new OFNC T-Shirt and 300 shirts of various sizes were printed for sale.

GILLIAN MARSTON
Chair, Education & Publicity Committee

Excursions and Lectures Committee

This Committee took great pleasure in arranging (and attending) 36 trips, ten monthly meetings (including the ABM) and the Soirée. We had one bus trip to Montreal (Biodome, etc.); the rest were by car pool leaving from either Lincoln Fields or Elmvale Acres. The monthly meetings from September to December were held at the Neatby Building, Agriculture and Agri-food Canada because the CMN was undergoing renovations. These facilities were quite satisfactory. We had 11 birding trips, 2 insect trips, 1 on plants, 1 on fungi, lichens and ferns, 1 on glaciation and the landscape, and 17 general natural history outings. Trips a little further afield (wetlands near Spencerville and snowshoeing in Algonquin Park) were very popular as were two mid-week events (early morning birding and a museum visit).

The Soirée was well-attended because many former Macoun Club members were specially invited.

FENJA BRODO
Chair, Excursions & Lectures Committee

OFNC Executive Committee

The Executive Committee met once to review issues and consider strategic alternatives during 2006.

MICHAEL MURPHY
Chair, Executive Committee

Finance Committee

The Finance Committee met three times during the year. Highlights include:

The Committee recommended, effective for the 2006-07 year, an increase in individual membership from $28.00 to $33.00 and an increase in family membership from $30.00 to $36.00. A subscription to CFN will be similarly increased.

Finance Committee considered a request from the Ottawa Riverkeepers to fund the printing of the first River Report for the Ottawa River. The report supports the objectives of the Club. Council agreed with the recommendation to provide $10,000 from the Groh bequest for this purpose.

A proposed budget for 2006-07 was developed and submitted to Council. A deficit of $13,400 was forecast for the Club and a deficit of $8,000 was forecast for the *Canadian Field-Naturalist*. Finance Committee emphasized the need to raise additional funds since these deficits cannot continue.

ANN MACKENZIE
Chair, Finance Committee

Fletcher Wildlife Garden

The Fletcher Wildlife Garden has completed another successful year. Wildlife continues to make good use of it and several new species have been added to our lists. The Management Committee met eleven times during the year. The 12th meeting was an end of season volunteer appreciation attended by about 30 people.

On March 24th in Toronto FWG was presented with the Ontario Association of Landscape Architects' 2006 Certificate of Merit for Service to the Environment. This award was later featured at Agriculture and Agri-food Canada's volunteer appreciation event.

Volunteers contributed over 3000 hours, mainly on Friday and Sunday mornings or Wednesday evenings. This year in addition to work in the Backyard Garden there was extensive work to extend the Butterfly Meadow, with plantings of native perennials, trees and shrubs. Sections of split rail fencing and rock piles were also added. Flowers were planted in the Ash Woods by a Pathfinder (Girl Guides) group.

Our struggle with invasive species continues. Garlic mustard and buckthorn are fairly well under control, but not eliminated. Pale swallow-wort is more difficult to remove without damage to other plants. We are reduced to measures to prevent overgrowth and seed production in critical areas while we wait for biocontrol methods. A group of Ontario Stewardship Rangers and a group from Nepean High School visited to help with invasive control.

About 30 people attended our International Migratory Bird Day event in May and a similar number visited during the Central Experimental Farm Open House. Our display was at the Wildlife Festival and at Agriculture and Agri-food Canada for Environment Week. FWG was used for 4 OFNC excursions, and by one school class and a field trip for the Monarch Teachers' Network. Talks were presented to three outside groups.

Our fund-raising this year proved quite successful. The annual Plant Sale raised almost $3000. A grant from Human Resources and Skills Development Canada allowed us to employ a summer student for 10 weeks. She operated the Interpretation Centre, worked with visitors, prepared materials for displays and the Backyard Garden and made and recorded wildlife observations. Once a week she provided activities for a children's day camp from Carleton University. The TD Friends of the Environment Foundation funded the printing of a brochure and contributed to remodeling of the map sign by the parking area. At third grant from the Evergreen Foundation. in the form of a gift card for Home Depot, also helped with the sign and the Butterfly Meadow work.

Our web site (http://www.ofnc.ca/fletcher.php) has been improved with news of recent events and observations and a plant database.

DAVID HOBDEN
Chair, Fletcher Wildlife Garden Committee

Macoun Club Committee

The Committee met once, and otherwise coordinated the weekly and monthly planning by telephone and e-mail. Committee members supervised or gave presentations at 17 indoor meetings, and led 16 field trips.

For the second year running, the Macoun Club was without a high-school aged group (our Seniors). Almost all recruiting efforts now are focused on building a strong Junior group that, growing up in Macoun Club, should eventually re-establish the Seniors.

As the year drew to a close, we were advised by our co-sponsor, the Canadian Museum of Nature, that it would not be able to provide any meeting space during the remainder of the renovation period at the Victoria Memorial Museum Building (to 2009). The Museum has, however, warehoused the Macoun Club's collections and file cabinets, and expressed a willingness to assist in other ways.

Issue No. 60 of the Macoun Club's annual publication, *The Little Bear*, was put together by a young member and his family. It was distributed to members at the annual party in June.

ROBERT E. LEE
Chair, Macoun Field Club

Membership Committee

The distribution of the membership for 2006 is shown in the table (on next page), with the corresponding numbers for 2005 in brackets. "Others" represent, for the greatest part, affiliate organizations that receive complimentary copies of the Club's publications. Local membership (within 50 km of Parliament Hill) was 684 and 680 in 2005 and 2006, respectively. The reduction of 11 in total membership is a continuation of this trend in recent years and presents a challenge to the Club.

This year, the Club lost a long time member, John Cameron, who joined the Club in 1970. In particular, his contribution to the Education and Publicity Committee must be acknowledged.

HENRY STEGER
Chair, Membership Committee

Publications Committee

The Publications Committee met three times in 2006, one of these in conjunction with the Finance Committee.

Four issues of *The Canadian Field-Naturalist* were published in 2006: Volume 118(4) and Volume 119(1,2,3). These

	CANADIAN		USA		OTHER		TOTAL	
Individual	401	(408)	16	(18)	5	(5)	422	(431)
Family	332	(331)	1	(2)	2	(1)	335	(334)
Sustaining	9	(11)	0	(0)	0	(0)	9	(11)
T and L	6	(6)	0	(0)	0	(0)	6	(6)
Honorary	25	(26)	0	(0)	0	(0)	25	(26)
Life	42	(41)	6	(6)	1	(1)	49	(48)
Other	30	(31)	1	(1)	1	(1)	32	(33)
Total	845	(854)	24	(27)	9	(8)	878	(889)

four issues contained 666 pages; 60 articles; 28 notes; 56 book reviews; 115 new titles; 2 commemorative tributes; 20 pages of News and Comments; 4 pages of miscellany; and a 28 page index. No funds were drawn from the Manning Memorial Fund. Re: electronic publishing, the OFNC web-site now carries the table of contents; all of the abstracts of articles and notes; and the News and Comments from each issue, as well as the annual indices. The committee feels that this is as far as we should go in this regard for the foreseeable future. Publishing costs are still a matter of concern.

Volume 40 of *Trail & Landscape* was published in four issues containing 226 pages. Issue 4 contains the 5-year index for Volumes 36 – 40. Preparation of the second 20-year index is underway. Costs have risen because of the loss of the Canadian Heritage subsidy for mailing.

Respectfully submitted,

RONALD E. BEDFORD
Chairman, Publications Committee

Auditor's Report

To The Members of THE OTTAWA FIELD NATURALISTS' CLUB

I have audited the statement of financial position of THE OTTAWA FIELD-NATURALISTS' CLUB as at September 30, 2006, the statement of changes in net assets, the statement of operations, and the statement of cash flows for the year then ended. These financial statements are the responsibility of the organization's management. My responsibility is to express an opinion on these financial statements based on my audit.

Except as explained in the following paragraph, I conducted my audit in accordance with Canadian generally accepted auditing standards. Those standards require that I plan and perform an audit to obtain reasonable assurance whether the financial statements are free of material misstatement. An audit includes examining, on a test basis, evidence supporting the amounts and disclosures in the financial statements. An audit also includes assessing the accounting principles used and significant estimates made by management, as well as evaluating the overall financial statement presentation.

In common with many non-profit organizations, THE OTTAWA FIELD-NATURALISTS' CLUB derives some of its revenue from donations and fund-raising activities. These revenues are not readily susceptible to complete audit verification. Accordingly, my verification of these revenues was limited to the amounts recorded in the records of THE OTTAWA FIELD-NATURALISTS' CLUB, and I was not able to determine whether any adjustments to the recorded amounts might be necessary.

In my opinion, except for the effects of adjustments, if any, which I might have determined to be necessary had I been able to satisfy myself concerning the completeness of the revenue referred to in the preceding paragraph, these financial statements present fairly, in all material respects, the financial position of the organization as at September 30, 2006, and the results of its operations and cash flows for the year then ended in accordance with Canadian generally accepted accounting principles.

JANET M. GEHR

5. Statement of Changes in Net Assets

a) Unrestricted other revenue includes the balance of a bequest of $23,717 from the Estate of Mildred Groh.

b) Unristricted other expenses: a donation to enable the publication of the River Keepers' River Report.

c) Seedathon Expenses: birdseed for club feeders, $1314.

6. Publication Liability

An annual membership fee or subscription entitles the member/subscriber to four issues of *The Canadian Field-Naturalist* based on a calander year. As the year end of the Club is September 30, the Club incurs a liability for publishing the fourth issue of each publication.

At this time, however, the publication of *The Canadian Field-Naturalist* is running late. At September 30, 2006, the Club owes members/subscribers issue number 3 and 4 of 2005 and three issues of 2006. Although most of the work preparing these publications is done by volunteers, the Club must pay for printing and mailing. Based upon recent costs, it is estimated that the Club has a liability of $68,000 for the outstanding issues. This amount will be reduced by page charges to the authors in the amount of 40% of the printing costs.

The Ottawa Field-Naturalists' Club Summary of Significant Accounting Policies

September 30, 2006

1 Nature of Business

The organization is non-profit and incorporated under the laws of Ontario (1884). The organization promotes the appreciation, preservation, and conservation of Canada's natural heritage. It encourages investigation and publishes the results of the research in all fields of natural history and diffuses information on these fields as widely as possible. It also supports and cooperates with other organizations engaging in preserving, maintaining or restoring environments of high quality for living things.

2. Financial Instruments

The organization's financial instruments consist of cash, accounts receivable, marketable securities, and accounts payable. Unless otherwise noted, it is the management's opinion that the organization is not exposed to significant interest, currency, or credit risks arising from these financial instruments. The fair value of these instruments approximate their carrying values, unless otherwise noted.

3. Capital Assets

Capital assets in excess of $4,000 cost are recorded as assets at cost and amortized on a straight-line basis. These assets have been fully amortized.

4. Revenue Recognition

Revenue is recognized when earned for donations and fund-raising when received.

5. Foreign Currency

Transactions during the year in U.S. dollars have been converted in the accounts to Canadian dollars at the exchange rate effective at the date of the transaction. All monetary assets in U.S. dollars at year end have been converted to Canadian dollars at the rate effective on Sept. 30, 2006.

Gains or losses resulting therefrom are included in revenue or expenses.

Advice for Contributors to *The Canadian Field-Naturalist*

Content

The Canadian Field-Naturalist is a medium for the publication of scientific papers by amateur and professional naturalists or field biologists reporting observations and results of investigations in any field of natural history provided that they are original, significant, and relevant to Canada. All readers and other potential contributors are invited to submit for consideration their manuscripts meeting these criteria. The journal also publishes natural history news and comment items if judged by the Editor to be of interest to readers and subscribers, and book reviews. Please correspond with the Book Review Editor concerning suitability of manuscripts for this section. For further information consult: A Publication Policy for the Ottawa Field-Naturalists' Club, 1983. *The Canadian Field-Naturalist* 97(2): 231-234. Potential contributors who are neither members of *The Ottawa Field-Naturalists' Club* nor subscribers to *The Canadian Field-Naturalist* are encouraged to support the journal by becoming either members or subscribers.

Manuscripts

Please submit by post **to the Editor,** in either English or French, **three** complete manuscripts **written in the journal style.** Manuscripts may also be submitted (one copy) by e-mail. The research reported should be original. It is recommended that authors ask qualified persons to appraise the paper before it is submitted. All authors should have read and approved it. Institutional or contract approval for the publication of the data must have been obtained by the authors. Also authors are expected to have complied with all pertinent legislation regarding the study, disturbance, or collection of animals, plants or minerals. The place where voucher specimens have been deposited, and their catalogue numbers, should be given. Latitude and longitude should be included for all individual localities where collections or observations have been made.

Manuscripts should be printed on standard-size paper, **doublespaced throughout,** generous margins to allow for copy marking, and **each page numbered.** For Articles and Notes provide a bibliographic (citation) strip, an abstract, and a list of key words. Generally, words should not be abbreviated but use SI symbols for units of measure. The names of authors of scientific names may be omitted except in taxonomic manuscripts or other papers involving nomenclatural problems. "Standard" common names (with initial letters capitalized) should be used at least once for all species of higher animals and plants; all should also be identified by scientific name.

The names of journals in the Literature Cited should be written out in full. Unpublished reports and web documents should not be cited here but placed in a separate Documents Cited section. List the captions for figures numbered in arabic numerals and typed together on a separate page. Present the tables each titled, numbered consecutively in arabic numerals, and placed on a separate page. Mark in the margin of the text the places for the figures and tables.

Check recent issues (particularly Literature Cited) for journal format. Either "Canadian" or "American" spellings are acceptable in English but should be consistent within one manuscript. **The Oxford English Dictionary, Webster's New International Dictionary** and le **Grand Larousse Encyclopédique** are the authorities for spelling.

Illustrations

Photographs should have a glossy finish and show sharp contrasts. Electronic versions should be high resolution. Prepare line drawings with India ink on good quality paper and letter (don't type) descriptive matter. Photographic reproduction of line drawings should be **no larger than a standard page.** Write author's name, title of paper, and figure number on the lower left corner or on the back of each illustration.

Reviewing Policy

Manuscripts submitted to *The Canadian Field-Naturalist* are normally sent for evaluation to an Associate Editor (who reviews it or asks another qualified person to do so), and at least one other reviewer, who is a specialist in the field, chosen by the Editor. Authors are encouraged to suggest names of suitable referees. Reviewers are asked to give a general appraisal of the manuscript followed by specific comments and constructive recommendations. Almost all manuscripts accepted for publication have undergone revision—sometimes extensive revision and reappraisal. **The Editor makes the final decision** on whether a manuscript is acceptable for publication, and in so doing aims to maintain the scientific quality, content, overall high standards and consistency of style, of the journal.

Special Charges — Please take note

Authors **must share in the cost of publication** by paying $90 for each page, plus $30 for each illustration (any size up to a full page), and up to $90 per page for tables (depending on size). Authors may also be charged for their changes in proofs. Reproduction of color photos is extremely expensive; price quotations may be obtained from the Editor.

Limited journal funds are available to help offset publication charges to authors without grants or institutional support. Requests for financial assistance should be made to the Editor when the manuscript is submitted.

Reprints

An order form for the purchase of reprints or pdf will accompany the galley proofs sent to the authors. Invoices for publication costs will be sent when the submission is published.

Newbury, Tina L., Neal P. P. Simon, and Tony E. Chubbs. 2007. Moose, *Alces alces*, winter browse use in central Labrador. Canadian Field-Naturalist 121(4): 359-363.

To determine the effect of forestry practices on the availability of winter Moose forage, we recorded Moose browse along four 250 m transects in each of five forest regeneration ages. Browse use was greater on 20- and 30-year-old regenerating stands as compared with recently clearcut stands (5 and 10 years old) or mature forest (> 150 years old). Willow (*Salix* sp.) followed by White Birch (*Betula papyrifera*) had the highest proportion of browsing by Moose.

Key Words: Moose, *Alces alces,* browse, logging, Labrador.

Since the early 1950s, Moose (*Alces alces*) have expanded into Labrador, independent of introductions on the Labrador coast (Mercer and Kitchen 1969; Dalton 1986*; Chubbs and Schaefer 1997). Conversions of mature forests into early and mid-successional seres are partly responsible for Moose increases in most of North America (Bergerud and Manuel 1968; Collins and Helm 1997; Rempel et al. 1997) since Moose tend to be associated with mid-successional forests (Bergerud and Manuel 1968; Telfer 1974; Pierce and Peek 1984; Collins and Helm 1997; McCracken et al. 1997; McLaren et al. 2000). It is unlikely that the first expansion of Moose into Labrador resulted from forest cutting; most cutting is limited to discrete areas isolated from the historical distribution of Moose in eastern Canada and logging largely began in the late 1960s (FMDPT 2003*) after Moose had become established in Labrador (Chubbs and Schaefer 1997). However, anticipated increases in logging in Labrador (FMDPT 2003*) will likely increase the amount of forest in successional stages favorable to Moose, possibly increasing Moose densities.

Moose favor areas of highest forest productivity, preferring 5- to 15-year-old regenerating stands where vegetation reaches heights of 3 m and is thus available above snow (Dodds 1960; Bergerud and Manuel 1968; Telfer 1974; McLaren et al. 2000). The mosaic of food and cover produced by logging can benefit Moose. High quality food is important for storing winter fat and provides females with the nutrients required for rearing young (Leptich and Gilbert 1989), while thermal cover is important for energy conservation (Schwab and Pitt 1991). Early and mid-aged clearcuts are favorable to Moose relative to forested stands in part due to more total browse (Telfer 1974; Schwab et al. 1987; Collins and Helm 1997) and because wind exposure reduces snow depths (Schwab et al. 1987). Early regenerating and pre-commercially thinned Balsam Fir (*Abies balsamea*) stands may also attract Moose, depending on site type (Thompson et al. 1992; McLaren et al. 2000).

There is considerable geographical and seasonal variation in Moose diets, yet coarse patterns exist (Peek 1974). In boreal forests during winter, Moose make high use of White Birch (*Betula papyrifera*), Mountain Maple (*Acer spicatum*), and Balsam Fir saplings, willow (*Salix* sp.), and with lesser amounts of Red-osier Dogwood (*Cornus stolonifera*), Pin Cherry (*Prunus pennsylvanica*), Mountain Ash (*Sorbus americana*), and *Viburnum* spp. (Dodds 1960; Bergerud and Manuel 1968; Peek 1974; Proulx and Joyal 1981; McLaren et al. 2000). Leaves and annual growth stems of the above species are dominant spring and summer forage. Additional summer foods include plants such as Yellow Water Lily (*Nuphar microphyllum*), horsetail (*Equisetum* sp.), fireweed (*Epilobium* spp), and sedges (*Carex* spp.) (Dodds 1960; Irwin 1985).

To determine the effects of forest harvesting on Moose browse, we documented Moose browsing across regenerating clearcuts of four ages (5 to 30 years old) and mature, uncut forests.

Study Area

The study was conducted from 28 June to 10 August 2004 within 40 km of Happy Valley-Goose Bay (53°19'N, 60°25'W), Newfoundland and Labrador, Canada (Figure 1). Sites were located in the High Boreal Forest Ecoregion of Labrador (Meades 1990*); this region contains the most productive forests for commercial timber in Labrador (Wilton1959; Lopoukhine et al. 1975). The moderately rolling terrain is dominated by Black Spruce (*Picea mariana*) and Feather Moss (*Pleurozium schreberi*) forest at the higher elevations and Balsam Fir/Black Spruce/White Birch forest at slightly lower elevations (Lopoukhine et al. 1975). This area experiences a mean annual temperature of -0.5°C (mean monthly range: -18.1 to 15.4°C) and precipitation amounts of 949 mm, half of which falls as snow (Environment Canada Climate Normals: http://www.msc-smc.ec.gc.ca; viewed 27 September 2004). Snow remains on the ground from October through June. Approximately 12% of this study area was commercially harvested from the late 1960s to 2004 (FMDPT 2003*). The area is accessible to hunters and the most recent density estimates reported 0.168 Moose/km^2 in 1994 (Chubbs and Schaefer 1997).

Methods

We established twenty 250 m-long transects in different stands, with four transects representing four clearcut ages (approximately 30, 20, 10, and <5 years following cutting) and uncut mature (>150 years old) forest. We selected stands ranging from 30 to 700 ha and those within the same age group were chosen as far apart as possible (≥ 700 m) while still being accessible. Prior to harvest, stands were dominated by Black Spruce and classified as commercial, i.e., supporting > 100 m^3 of timber per ha with canopy height ranging from 9.5 to 18.5 m tall and crown closure ranging from 50 to 75%. Our mature forest transects reflected this variation and all sites had regenerated. Transects in harvested stands started at commercial mature forest edges and were oriented to avoid all other stand edges, roads and patches of remnant forest.

Transects consisted of evenly spaced plots at 50 m intervals. Each plot consisted of five 4.5 m^2 circular subplots: one central and the remaining four in the cardinal directions 10 m from the centre. Within each subplot, plant species, number of stems and occurrence of Moose browsing were recorded.

Results

Most browsing occurred in the 20- and 30-year-old stands, with willow being the most proportionately, 0.50 and 0.80, respectively, browsed species. Willow accounted for only 0.8% of total stems but represented 16.5% of the total stems browsed across 20- and 30-year-old stands. The second most proportionately browsed species was White Birch (0.33 and 0.48 in 20- and 30-year-old stands, respectively). Considerably smaller proportions of Mountain Alder (*Alnus crispa*), Balsam Fir and Black Spruce were browsed. There was virtually no browsing in clearcuts < 15 years old and forests > 150 years old.

Discussion

Throughout their range and between seasons, species browsed by Moose varies, but tends to be dominated by willow when available (Peek 1974; McCracken et al. 1997; Collins 1999). Similarly, we found that willow was the most proportionately browsed species in Labrador. Our second most proportionately browsed species, White Birch, was also a prominent Moose browse throughout Canada (Dodds 1960; Peek 1974). However, in contrast to other regions (Dodds 1960; Bergerud and Manuel 1968; Thompson et al. 1992) proportionately little Balsam Fir was browsed in our study. Balsam Fir is generally a winter food (Dodds 1960) and may be selected only when deciduous species are unavailable or where Moose densities are high (McLaren et al. 2000). Moose are reported absent from apparently suitable habitat in Labrador and are possibly limited by Wolf (*Canus lupus*) predation, illegal hunting, and snow depths (Trimper et al. 1996). Although snow depth could limit food supply (Schwab et al. 1987), it also increases expended energy (Schwab and Pitt 1991). Illegal hunting, Wolf predation and energy costs of snow depth may depress Moose populations enough that they can forage on the preferred willow and White Birch rather than resorting to Balsam Fir.

Our finding of more Moose browsing in 20- and 30-year-old stands is similar to other studies that found greater amounts of browse and Moose densities in regenerating clearcuts (Telfer 1974; Schwab et al. 1987; Leptich and Gilbert 1989; Collins and Helm 1997; Thompson et al. 1999; McLaren et al. 2000). However, our peaks in Moose browsing occurred 10 – 15 years later than suggested by Dodds (1960) and Telfer (1974), likely due to the slower regeneration rate in our study area than in more southerly Moose ranges. Our results suggest that increases in forest cutting may increase Moose densities by enhancing browse production. However, the lack of browsing on less preferred species (e.g., Balsam Fir) indicates Moose are probably not limited by winter browse and therefore Moose may not increase as rapidly as in other areas. Although we found few browsed stems outside 20 – 30 year old clearcuts, Moose may use these areas to graze on herbs during summer and fall. Browse surveys alone may not be enough to quantify Moose diets – fecal and rumen analyses and foraging observations would help to better determine seasonal Moose forage preferences (McCracken et al. 1997).

Increased Moose densities resulting from logging may enhance recreational and sustenance activities; e.g., viewing and hunting. However, increased Moose densities are believed to increase Woodland Caribou

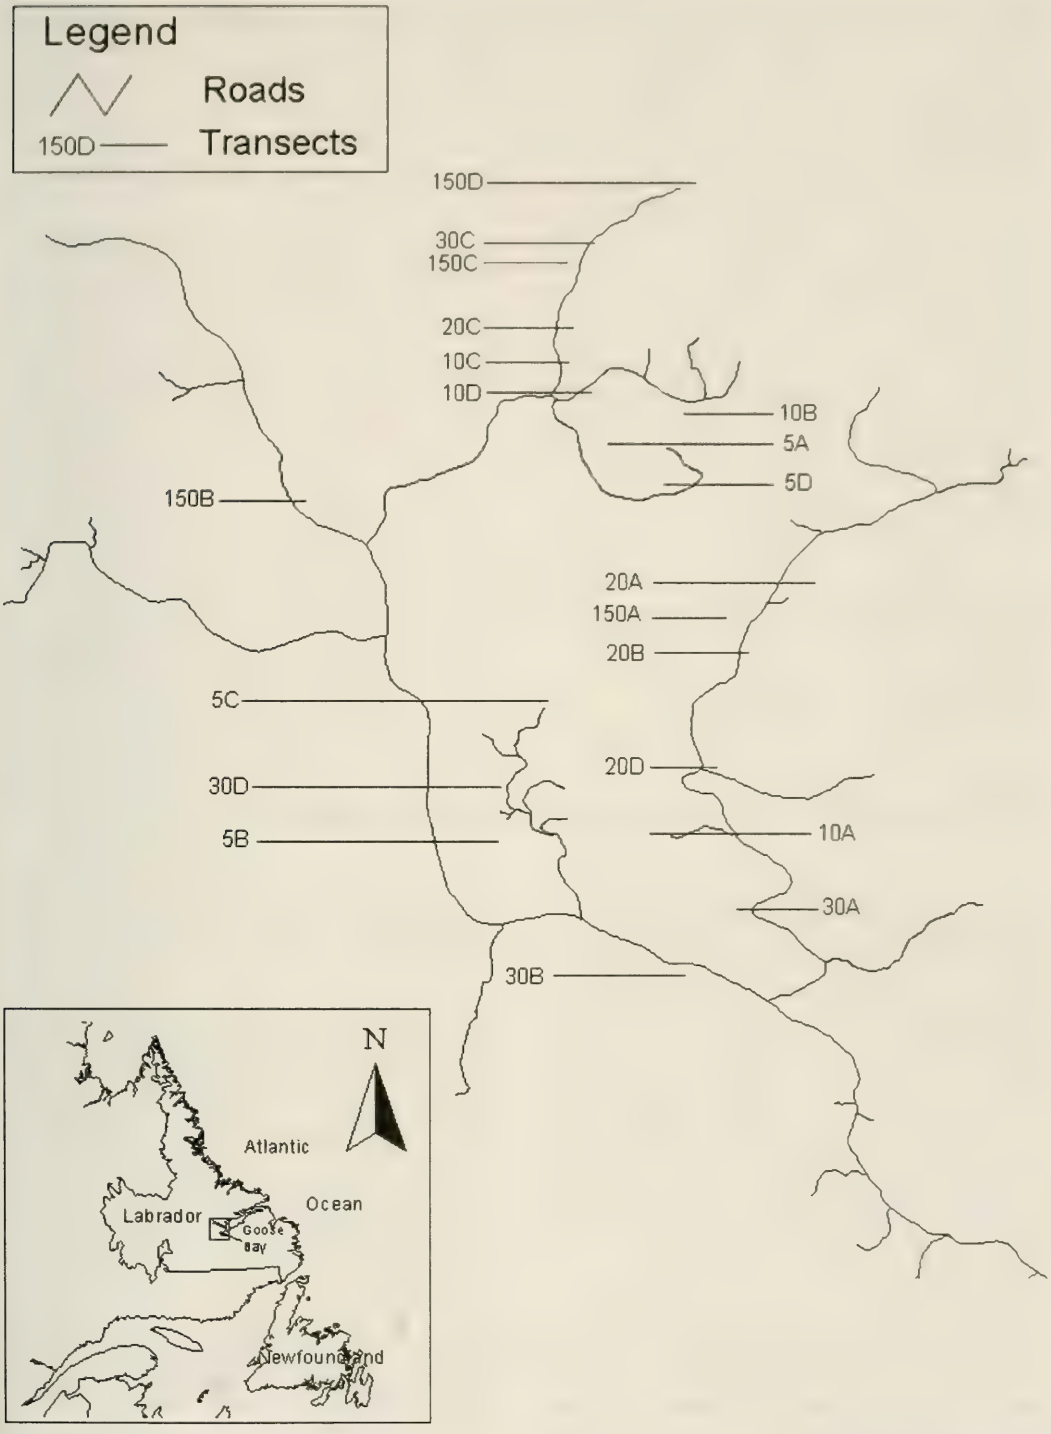

FIGURE 1. Study area showing the locations of each of the four (A, B, C and D) transect locations for each clearcut age (5, 10, 20, 30, and 150 years).

(*Rangifer tarandus*) mortality possibly thorough an influx of large predators; e.g., Wolves (Bergerud and Elliot 1986; Klein 1991; Seip 1992; Schaefer et al. 1999) and Black Bears, *Ursus americanus* (Mahoney and Virgl 2003). Boreal populations of Woodland Caribou are threatened in Labrador (Schmelzer et al. 2004*), so it may be desirable to reduce Moose forage, notably White Birch and willow, on regenerating clearcuts. Our results indicate that accelerating the passage of clearcuts through earlier successional stages by aggressive Black Spruce planting and targeting Moose forage in pre-commercial thins would have the greatest negative impact on Moose winter forage.

Acknowledgments

We thank S. Barr, R. Dove, M. Hynes, D. Jacque, and K. Osmond for their assistance with data collection and entry. We thank F. Schwab and an anonymous reviewer for the helpful comments on the manuscript. D. Jennings and J. Thomas provided maps and forest stand information. This study was supported through funding and in-kind support from Human Resources and Skills Development Canada, Innu Nation, Newfoundland and Labrador Department of Natural Resources, and the Western Newfoundland Model Forest.

Movements of Transient Coyotes, *Canis latrans,* in Urbanized Eastern Massachusetts

JONATHAN G. WAY[1,2]

[1]Science Department, Barnstable High School, 744 West Main Street, Hyannis Massachusetts 02601 USA; e-mail: jw9802@yahoo.com.
[2]Eastern Coyote Research, 89 Ebenezer Road, Osterville, Massachusetts 02655 USA

Way, Jonathan G. 2007. Movements of transient Coyotes, *Canis latrans*, in urbanized eastern Massachusetts. Canadian Field-Naturalist 121(4): 364-369.

I document the movements of five transient (or nomadic) eastern Coyotes (*Canis latrans*) in heavily urbanized eastern Massachusetts. Linear movements from capture location to end location varied from 23.0 to 100.5 km and averaged 63.8 ± 52.0 km for two females and 38.7 ± 17.2 km for three males ($t = 0.657$, $df = 1.15$, $P = 0.618$). Transients ranged in age between 1-2 yr old. There was no relationship between Coyote body weight and dispersal distances ($r = 0.389$, $P = 0.518$). Coyotes travel long distances even in human-dominated areas, allowing transients to find vacant territories. Because of the ability of Coyotes to colonize and recolonize areas, I recommend that Coyote management efforts focus more on educating the public about actual Coyote behavior and their life history needs than on killing them.

Key Words: Eastern Coyote, *Canis latrans*, dispersal, human-dominated landscapes, movements, suburban, transient, urbanized Massachusetts.

Coyotes (*Canis latrans*) typically live in packs consisting of a breeding pair, resident associates (helpers), and pups of the year (Gese et al. 1996; Way et al. 2002a). Coyote packs defend a territory while nomadic or transient Coyotes, usually young, but sometimes old individuals (see Way 2007a), travel among a matrix of territories as they disperse from their natal range (Harrison 1992; Way et al. 2002a). Individual Wolves (*Canis lupus*) and Coyotes are known to disperse several hundred kilometers from their natal range (Fritts 1983; Carbyn and Paquet 1986; Gese and Mech 1991; Harrison 1992; Mech and Boitani 2003a), which facilitates recolonization of areas where control actions limit their numbers or where they are expanding their range (Parker 1995; Mech and Boitani 2003a).

Movements of dispersing transient Coyotes have been documented in rural/forested areas (Harrison 1992), agricultural landscapes (Person 1988), and in southern Canada (Carbyn and Paquet 1986). Coyotes have also been documented to travel across seemingly disparate areas, such as wide canals (Way 2002), islands (Thomas and Dibblee 1986), and on drifting pack ice (Chubbs and Phillips 2002). However, aside from one documented Coyote in urban/agricultural southern Canada (Rosatte 2002), there are no data on transient/ dispersing Coyote movements in urbanized areas. Documenting the movement of transient Coyotes in urbanized areas will give managers data on how Coyotes move in these landscapes compared to more rural environs (e.g., Harrison 1992; Gese et al. 1996). This could have practical implications. For example, if transient Coyotes do not move far in urbanized locales (because of the high amount of roads) then localized control efforts may be more successful in reducing Coyote numbers in those regions; conversely, if the opposite is true (i.e., Coyotes move similar distances in urban and rural areas), then control efforts would likely be less successful, unless targeting a specific individual(s). This paper, part of a larger ongoing study on Coyote ecology (Way et al. 2001; Way et al. 2002a; Way et al. 2004) in eastern Massachusetts, documents the movement of transient Coyotes in a heavily urbanized region.

Study Areas

This research took place in two urbanized locations: Cape Cod and the towns and cities north of Boston (Figure 1). Most research conducted on the heavily urban north edge of Boston (~100-150 km^2; 42.43°N, 71.06°W) took place in the cities of Revere (3089 people/km^2, housing density = 1318/km^2), Everett (4345 people/km^2, housing density = 1817/km^2), and Malden (4291 people/km^2, housing density = 1800/km^2) (U.S. Census Bureau 2000 estimates). The area is characterized by high-density housing with small woodland areas (including cemeteries) non-strategically situated in towns and cities. Coyotes were captured and spent most of their time in these wooded, green areas as the high-density housing areas were often fenced and provided nowhere for Coyotes to travel, except for main roads. Railroad tracks and holes in some of the fences provided small corridors between some of the green areas (Way and Eatough 2006).

Cape Cod research was conducted within Barnstable County, Cape Cod, Massachusetts (approximate study area 250 km^2), with a concentration in the town/city of Barnstable (although called a town, Barnstable is technically a city; 41.67°N, 70.28°W; land area = 155.5 km^2).

Human population density in the town/ city of Barnstable was 308 people/km^2 and housing density was 161/km^2, while the entire Barnstable County (3382 km^2) averaged 217 people/km^2 and 144 houses/km^2 (U.S. Census Bureau 2000 estimates). The town/ city of Barnstable has a distinct rural-urban gradient within its borders; the highest and lowest densities of people were found in urban Hyannis (556 people/km^2, housing units = 328/km^2) and rural West Barnstable (89/km^2, housing units = 39/km^2) (Cape Cod Commission 1998*). Road density, defined as centerline km of roadway per km^2, was 4.7 for the town of Barnstable and 4.0 for Barnstable County (Cape Cod Commission 1998*). Cape Cod is characterized by being residential as well as having numerous small (5-10 ha) and a few large (~1000 ha) conservation areas interspersed throughout. Most of the neighborhoods are not fenced, however, and Coyotes were readily able to travel through these areas to access various portions of their home range (Way et al. 2004). Coyote pack territories were roughly 30 km^2 and were non-overlapping, similar to more rural areas (Gese et al. 1996; Way et al. 2002a).

Methods

Coyotes were captured by box trap (Way et al. 2002b) then radio-collared or radio-implanted (juveniles – i.e., pups of the year) using Telonics, Inc. (Mesa, Arizona) transmitters, aged based on tooth wear (Bowen 1982; Landon et al. 1998), weighed, blood drawn (ca. 4 cc), then released. Transient (or nomadic) Coyotes were classified as Coyotes who had no discernable territory and nomadically moved throughout the study areas, including within resident collared Coyote home ranges. These Coyotes are typically classified as young Coyotes that are in the process of dispersing from their natal pack (Way et al. 2002a).

Tracking protocols were described by Way et al. (2002a) and Way et al. (2004). Portable receivers (Custom Electronics, Urbana, Illinois, USA) and hand-held 3-element Yagi antennas were used to radio-track Coyotes both on foot and from a vehicle. Due to the highly developed landscape with many roads, I mostly radio-tracked in a vehicle as Coyotes did not react negatively to them as much as they did to people (e.g., by running away; Way 2007a; J. Way, unpublished data); occasionally I approached radio-collared Coyotes as closely as possible on foot without disturbing them. I used binoculars and video-cameras when observing Coyotes, and city street lights, nightscopes and occasionally headlights when following Coyotes at night with a vehicle (Way et al. 2002a; Way et al. 2004). Due to funding constraints, I did not use airplanes to search for Coyotes that left our study areas; extended trips were made in vehicles to locate missing Coyotes but this was often unsuccessful. Instead, I relied on recovering Coyotes from sightings by the public (n = 1), opportunistically receiving radio-locations in new areas (n = 1), and recovering carcasses from human-related kills (i.e., road-kill or gunshot; n = 3) Transient movement distances were calculated from where they were first captured (if not on natal territory) or from their natal territories (if known) to their final location when they either settled (i.e., established a resident home range in a new area) or died.

I used an independent sample two-tailed t-test to detect differences between male and female dispersal. Levene's test was used to detect for equal variance between samples; a significant Levene's result indicated that equal variances were not assumed. I correlated Coyote dispersal distances with body weight using two-tailed bivariate Pearson Correlation Coefficients (SPSS Inc., Chicago, Illinois) tests. I set significance at < 0.05.

Results and Discussion

I documented the movement of five transient Coyotes: one from north Boston and four from Cape Cod (Figure 2). Upon release, all Coyotes appeared to be in the process of dispersal as their movements were nomadic. Movements from capture to final location varied from 23.0 to 100.5 km and averaged 63.8 ± 52.0 km for two females and 38.7 ± 17.2 km for three males (Levene's Test = 0.030, t = 0.657, df = 1.15, P = 0.618). Although I had a low sample size, these movements were within the range of dispersal by transient Coyotes in more rural environments, with an average distance of 98 km for Coyotes in forested Maine (Harrison 1992), 16 – 152 km in rural Ontario (Kolenosky et al. 1978), 20 – 140 km in rural, agricultural Vermont (Person 1988), ≤ 30 km (depending on age class) in farmland-forested central Alberta (but up to 100 – 150 km; Nellis and Keith 1976), 12.7 – 17.9 km in the western United States (Robinson and Grand 1958), 35.7 km in Iowa (Andrews and Boggess 1978), 16 – 68 km (average = 48 km) in northern Minnesota (Berg and Chesness 1978), 36.4 km in New Mexico (Young and Jackson 1951), and 40.3 – 45.6 km (up to 161 km) in Wyoming (Young and Jackson 1951).

There was no difference between male and female transient movements and all were young (1 – 2 yr old) animals (Table 1), which is typical of when canids disperse (Harrison 1992; Mech and Boitani 2003a). Although I had a low sample size, it is noteworthy that a female exhibited the longest movements. Coyote #BN0402 traveled through nearly all of eastern Massachusetts, one of the most densely human populated areas in the country (U. S. Census Bureau 2000 estimates; Way 2007a). Additionally, female Coyote #0202 navigated across a 1 km canal to leave Cape Cod (Way 2002). However, caution should be taken with these low sample sizes and over-interpreting the results. For instance, as this paper went to press, Way (2008*) documented a yearling male Coyote that travelled 81.1 km, from the village of Centerville to

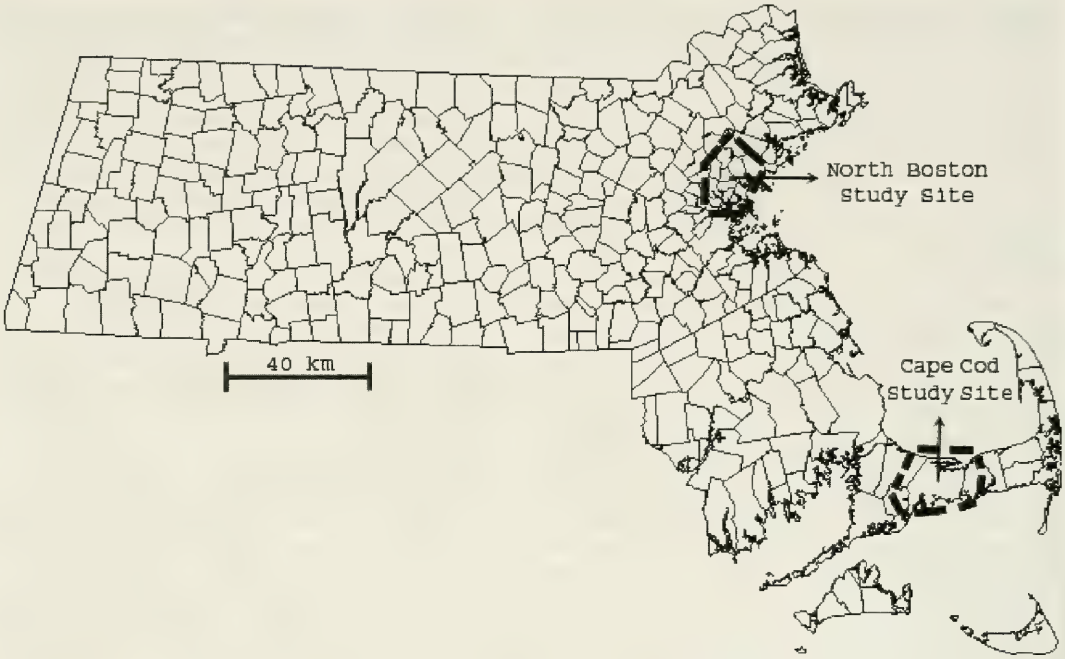

FIGURE 1. Map of the two Coyote study sites in eastern Massachusetts with polygons representing all of the towns in Massachusetts.

Hingham, Massachusetts, about 15 km southeast of Boston. This one animal's movement would have caused male Coyotes in this study to go from an average dispersal distance of 38.7 to 49.3 km. Thus, the male/female difference is not as important as the fact that this study is the first to document transient Coyote movements in urbanized locals.

Harrison (1992) found no sex specific statistical differences in Coyote dispersal in his Maine study, which might be expected for a monogamous species, but the maximal distance traveled (342 km) was by a female. Other studies corroborate these findings with individual females dispersing the farthest in their studies, such as 17.9 (vs. 12.7) km in the western United States (Robinson and Grand 1958), 323.2 km in Iowa (Andrews and Boggess 1978), 154 km in central Alberta (Nellis and Keith 1976), and 544 km from Riding Mountain National Park, Manitoba, to Saskatchewan, the furthest movement of a coyote on record (Carbyn and Paquet 1986). In fact, all long-distance movements were made by females except a male Coyote in Rosatte's (2002) study that moved 320 km in an agricultural region of southern Ontario (the most urban of the study sites after mine). However, most researchers claimed that these long-distance dispersals were rare.

The Boston Coyote likely exhibited a relatively straight-line dispersal through Boston and south to the edge of the Atlantic Ocean in southeastern Massachusetts where either the ocean stopped her movement and/or she paired up with a mate (Figure 2; Way

TABLE 1. Movements of transient (or nomadic) Coyotes in eastern Massachusetts

Coyote ID	Sex/Age (yr)	Start of dispersal[1]	Conclusion of dispersal[2]	Body weight (kg)	Minimum distance traveled (km)
#BN0402	Female (1)	April 2004	November 2004	13.6	100.5
#0301	Male (2)	December 2003	February 2005	18.5	57.1
#0401	Male (2)	February 2004	December 2005	14.5	23.0
#0202	Female (2)	January 2002	May 2002	19.1	27.0
#0205	Male (1.5)	March 2002	June 2003	15.2	36.1

[1]Represents when the animal was documented as a transient Coyote in the act of dispersal. Because all animals in this study were captured as transients and were likely off their natal ranges when captured, their respective capture location notes where I recorded their start of dispersal.

[2]Represents when an animal terminated nomadic movements or was recovered dead.

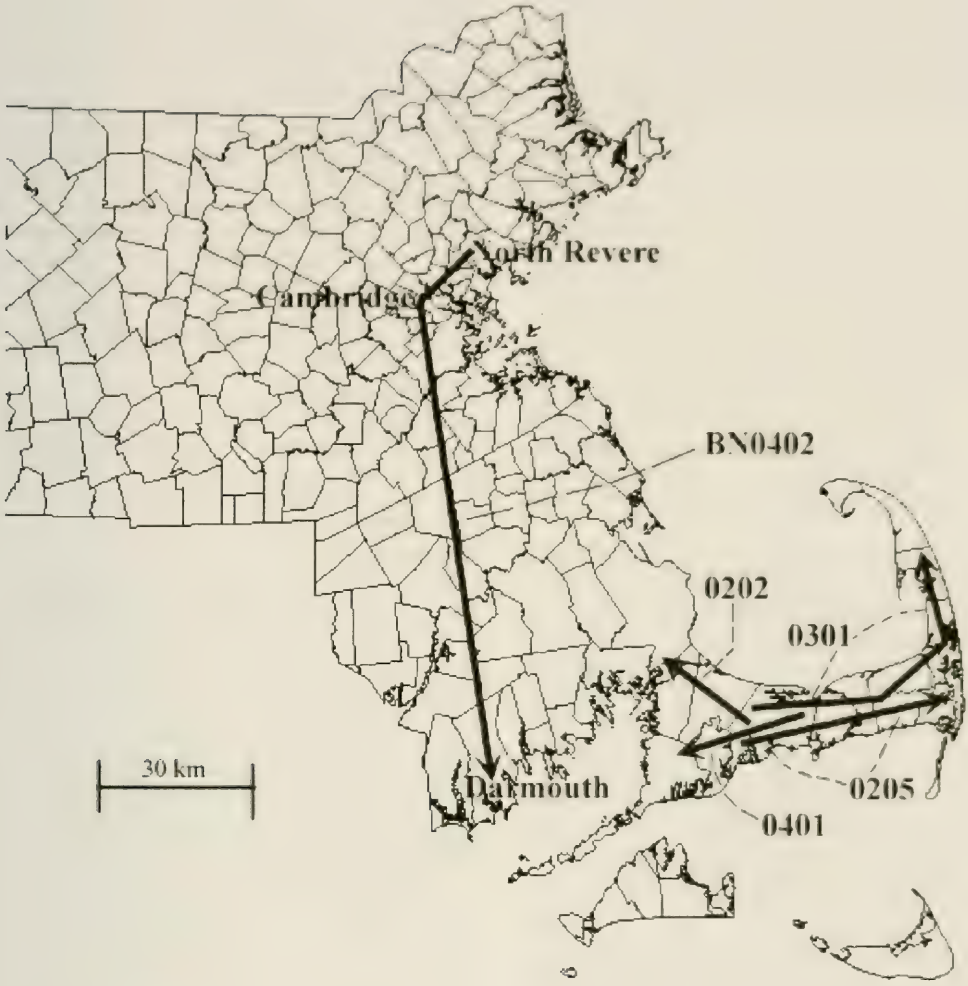

FIGURE 2. Movements of transient (or nomadic) Coyotes in eastern Massachusetts.

2007a). Because of the restricted movement paths possible for Coyotes dispersing on peninsular Cape Cod and because I did not sequentially track them when out of radio contact, it was difficult to assess movement direction. However, the four combined Coyotes were documented to travel throughout most of Cape Cod, radiating from the town of Barnstable study area (Figure 1), with two Coyotes each ultimately ending up both east and west of the Barnstable study site (Figure 2). Mech and Boitani (2003a: 15) noted that "In homogeneous habitat types, Wolves would probably disperse equally in all directions. However, no habitat type is homogeneous, and topography, Wolf density, and areas of human development no doubt play varying roles in steering dispersal, direction." Harrison (1992) noted that Coyotes in Maine often follow major rivers and that those water barriers often deflected and influenced Coyote dispersal, while Gese and Mech (1991) found that Wolves in Minnesota dispersed in relatively equal directions.

There was no relationship between Coyote body weight and distance traveled ($r = 0.389$, $P = 0.518$) with two relatively heavy and three light transient Coyotes (see Way 2007b for weight ranges), although caution should again be taken when inferring results because of low sample size. However, Gese and Mech (1991) also found no difference between wolf body weight and the age at dispersal or dispersal success. Yet Gese et al. (1996) discovered that Coyotes that dispersed from their natal pack in Yellowstone National

Park were often low ranking and had less access to food. One would presume that these Coyotes also weighted less than philopatric Coyotes.

Distances traveled by nomadic Coyotes in eastern Massachusetts represented minimum values because (1) most movements were made in a restricted, linear landscape (i.e., Cape Cod); (2) it was not known where all of the transients began dispersal (i.e., we did not capture them as juveniles within their natal ranges); and (3) it was not known if all localized (i.e., established or joined a pack) before death. If they were killed before settling then their potential dispersal distance may have been underestimated. Based on the time (months to one to two years) that I was not in contact with radio-collared Coyotes, I suspect that many Coyotes traveled the length of Cape Cod and only infrequently came into my study area. Coyotes can move long distances in short periods of time (Way et al. 2004) and I sporadically located these transients before they disappeared, presumably out of my study area.

The most accurate way to determine Coyote dispersal and subsequent transient movements is to radio-tag juveniles in their natal area and track how Coyotes disperse (e.g., Harrison 1992). However, dispersal is time intensive, expensive, and one of the most difficult of all population processes to document (Harrison 1992; Mech and Boitani 2003b). For example, I also radio-tagged nine additional juveniles (seven from Cape Cod; two from north of Boston) within their natal ranges but recovered no dispersal information on any of them because they either died on their natal territory (n = 5) or disappeared and were never relocated (n = 4). Thus, reporting transient Coyote movements in a range of landscapes, regardless of the sample size, is important.

In highly developed regions (e.g., eastern Massachusetts), it is likely that Coyotes travel across a gradient of urbanization (rural to urban) when dispersing. In other words, an "urban Coyote" would merely represent where that individual currently lives; that same individual could have originated from a much more rural location. For example, Coyote #BN0402 was captured in the process of dispersal in heavily urban north Boston (Revere, Massachusetts). She traveled southwest into heavily urban Cambridge, then vanished before being discovered in Dartmouth, Massachusetts (Way 2007a), a town that is rural-suburban with a large percentage of open space remaining (population density = 192/km^2, housing density = 71 km^2; U.S. Census Bureau 2000 estimates). She paired up with a male Coyote and produced pups in Dartmouth before dying of unknown causes in June 2005 in her recently established range.

Coyotes have colonized much of North America, including urbanized areas, south of the Arctic. While there may be times when individual(s) Coyotes may need to be removed from a population, widespread control efforts have never been successful at regulating Coyote numbers (Parker 1995), partly because of their well-documented dispersal and movement ability in a myriad of landscapes. The Coyote's persistence is nearly guaranteed throughout its range and the potential for (re)colonization of habitats ranging from rural to urban is very high. Therefore, I recommend that Coyote management efforts focus more on educating the public about actual Coyote behavior (e.g., Way 2005) and their life history needs than on killing them. As noted by Gompper (2002), the presence of Coyotes in northeastern North America and in cities, represents a natural range expansion of the species, not an exotic invasion, and the species is here to stay.

Acknowledgments

This study would not have been possible without the help from Tara Way, the Way family, Eric Strauss, and the Hyannis Animal Hospital (specifically, Larry Venezia and Paul McCartin) for the Cape Cod component of the research; the Saugus Animal Hospital (specifically, Bob Binder), David Eatough and Stephen Cifuni and his family for the Boston component of our study; and Boston College's Environmental Studies Program and Urban Ecology Institute for equipment purchases. Permits and protocols have been approved and obtained through Boston College and the Massachusetts Division of Fisheries and Wildlife to handle the animals, and from numerous private, town, and state lands that allowed us to put traps in the field and to track collared Coyotes. I appreciate all of these entities that provided documents and support, especially the towns/cities of Barnstable (including rangers, administrators, and animal control), Melrose, Revere, Everett, Malden, and Saugus, among others, for allowing me to use all or some of their land as if it were my own. I thank Gary Clabaugh for reporting the sighting of #BN0402 in his backyard in Dartmouth, Massachusetts, and for civic employees for reporting the carcasses of three others.

The Punctual Bufflehead, *Bucephala albeola*: Autumn Arrivals in Shoal Harbour Sanctuary, Vancouver Island, in Relation to Freeze-up

James K. Finley

10232 Summerset Place, Sidney, British Columbia V8L 4X2 Canada

Finley, James K. 2007. The punctual Bufflehead, *Bucephala albeola*: Autumn arrivals in Shoal Harbour Sanctuary, Vancouver Island, in relation to freeze-up. Canadian Field-Naturalist 121(4): 370-374.

Buffleheads are punctual in their return to wintering grounds on the Pacific coast. First arrivals appeared in Shoal Harbour Migratory Bird Sanctuary, southeastern Vancouver Island, on the 288th day of the year on average (± S.D. 2.3; n = 10), that is, 15 October. This vanguard preceded the first peak influx by about 15–20 days, and a second influx by about 24–26 days. First arrivals usually appeared by mid-morning, and included singles (females on two occasions) and small flocks of up to eight. First arrivals may represent a photoperiodic threshold, whereas subsequent peak influxes represent climatic thresholds associated with freeze-up. The phenology of Bufflehead autumn migrations is a good proxy indicator of the advance of the zero degree isotherm, and thus of climatic variability. The timing of their autumn migrations does not appear to have changed in the last half of the twentieth century, consistent with evidence that freeze-up has not advanced. Monitoring of their migrations, in conjunction with shore-based observations of freeze-up, would validate one-dimensional thermodynamic models of freeze-up, and provide a more ecologically meaningful index of climate change, at minimal cost.

Key Words: Bufflehead, *Bucephala albeola*, phenological precision, autumn arrivals, freeze-up, climate change.

Synchronicity of life cycles with environmental cues is a key determinant of fitness, survivorship and reproductive success. With growing public interest in the impacts of global warming, there has been a resurgence in documenting phenological phenomema as indicators of environmental change. In Britain, for example, the average arrival dates of twenty migrants have advanced by eight days in the last several decades, raising concern that asynchrony in biological cycles with climatic change will increase stress on species, particularly the specialists (Cotton 2003).

The Bufflehead is a specialist, occupying a narrow niche, and is remarkable amongst the seaducks in that its population has remained stable over decades (Gauthier 1993). In his monograph on the species, Erskine (1972), advised that "If you would become familiar with a bird, you must live with it, day by day through the seasons, following the activities that fill its life and add up to the picture conjured up by its name. So it is with the bufflehead. ... People fortunate enough to live on the water's edge may watch buffleheads from their breakfast table ...". I'm one of the fortunate ones, being able to observe Buffleheads from my breakfast table, overlooking Shoal Harbour Migratory Bird Sanctuary, Vancouver Island, since 1984.

I've long been fascinated by the strange circumstances and climatic events that caused the "Great Bufflehead Crash" on the night of 4 November 1940 in eastern Saskatchewan (Swallow 1941; Erskine 1972; Finley 2001), and I wait their arrival eagerly, as I simultaneously watch satellite images of anti-cyclonic systems breaking over the mountains. Here, I document the timing of their autumn arrival during the last decade, and attempt to relate this to the latest research in freeze-up phenology and climate change.

Methods

My bay-window observatory, situated in Sidney, British Columbia, overlooks Roberts Bay, part of Shoal Harbour Migratory Bird Sanctuary, southeastern Vancouver Island, one of the oldest marine migratory bird sanctuaries on the Pacific coast, established in 1931 (Dawe 1982). Between 1996 and 2005, I kept watch daily for first arrivals in September and October. At least once every morning and at the end of the day during October, I scanned the bay with the aid of binoculars or telescope. In practice, the bay was under observation semi-continuously from either my kitchen window or my study window; however, due to the routines of family life, first scans usually took place between 8:30 to 9:00 h and last scans between 16:00 and dusk. Observations on behaviour, numbers and sex composition were entered in a daily diary, and later transferred to a computer spreadsheet. In most years between 2000 and 2006, total numbers were recorded daily until mid-November. Periods when numbers increased abruptly by more than 30% on two consecutive days were considered as peak influxes.

Results

First arrivals appeared around the 288th day (± S.D. 2.3; n = 10; i.e., 15 October) of the Julian calendar (Table 1). They included singles on three occasions and flock sizes up to eight. Singles included "females" in two cases; drakes were always amongst the first arrivals, accounting for 14 of 38 (37%) of them. Most

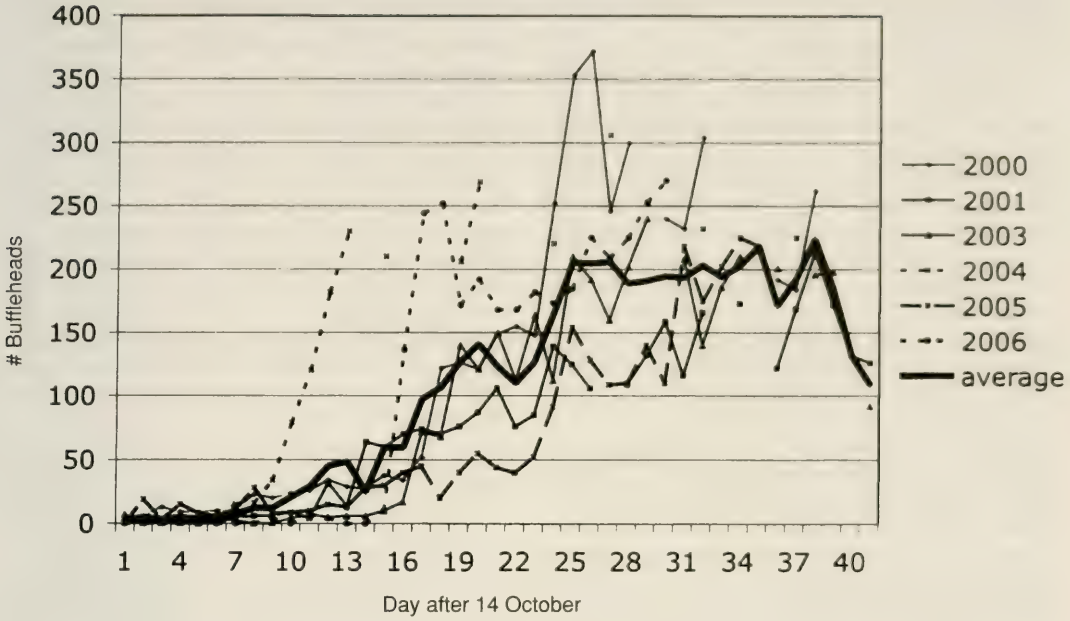

FIGURE 1. Buffehead phenology: autumn numbers of Buffleheads on Roberts Bay, Shoal Harbour Migratory Bird Sanctuary, mid-October to late November, in various years between 2000 and 2006.

arrivals appeared by 09:00, and they always appeared in the same general location (radius about 150 m), around the delta of an estuarine creek. Numbers until late October remained small, averaging less than 6% of peak numbers. First arrivals preceded the first peak influx by about 15 to 20 days (typically the end of October), and a second influx by about 24–26 days (7–9 November), though the first peak was sometimes not evident, e.g., 2001 and 2005 (Figure 1). The percentage of males on various days varied considerably, averaging 42 percent ($n = 38$), with no apparent trend during the influx period.

Discussion

Due to their high albedo and activity, male Buffleheads are difficult to overlook, and because Roberts Bay is just the right size, I'm confident that the data presented here are reliable. Their timing, first thing in the morning, indicates their propensity for nocturnal navigation. Though the precise timing is biased by my morning schedule, it is evident that they arrive sometime after dawn, conveniently around breakfast time, as enviously noted by Erskine (1972). On several occasions, it was apparent that they had just touched down, and on one occasion, 15 October 2003 ("All-Buffleheads Day"), I saw them fly in and land. First arrivals were often flighty, sometimes disappearing and returning during the day, or disappearing for several days, but most took up residence and courtship right away.

Throughout October and into November, new arrivals remain mostly in the core area where they initially landed, and intense courtship takes place before birds take up their feeding territories. This initial touch-down zone is a central arena in Bufflehead society, to which known individuals of monogamous pairs return year after year (Finley, unpublished). Such philopatry, or "home-loving" behaviour, is a genetic trait passed on over generations, providing a survival advantage through intimate knowledge of their environs, culturally transmitted through the wisdom of successful mature individuals. Thus, philopatric Buffleheads are "homing in" on their tribal territories, and they do so, in a punctual manner.

Buffleheads show a high degree of synchronicity and phenological precision in their life cycle, hatching out in latitude 52°N on Julian day 169.5 ± SE 1.6 (18 June; Evans et al. 2002) and, about 119 days later, arriving on their wintering grounds, in latitude 48°N. These life events, synchronized with the solar cycle, represent significant seasonal demarcations in the calendar of temperate boreal, aspen-parkland ecosystems. Not only do Buffleheads show punctuality by their solar calendar, but they also synchronize their

daily life precisely with light levels (Finley 2007). They are an exemplary model of precision and punctuality, daily and seasonally.

Erskine (1972: 128) noted that "Reported first arrivals are often single birds moving a month or even more before migration gets under way in earnest." Erskine also reported that only isolated individuals appeared before 10 October. He illustrated the isolines of migration fronts in 1962 over North America, although the entire coast of British Columbia fell into a zone of uncertainty between 11 and 21 October. Using published records and questionnaires, Erskine calculated arrival dates over the twentieth century for various locations on Vancouver Island and Puget Sound, Washington, noting that "few observers are in a position to observe bufflehead habitat daily or even weekly, and many first dates represent only the time of first visit to a particular area". Still, he found the averages were remarkably uniform around 18 October (S.D. ± 2 around five regional means, based on 45 records) for five locations on Vancouver Island between 1903 and 1962. Victoria averaged 18 October based on eight years between 1955-1962. If anything, the potential bias by discontinuous observation would be toward a later date as suggested by this study. Or, as Erskine has suggested (personal communication, 2008), first arrivals might appear slightly earlier in prime habitat like Roberts Bay, rather than in adjacent areas.

Erskine (1972) estimated that the first general movement from the breeding grounds began around 20 October, and observed that peak migration across the continent was highly concentrated during the first week of November, noting the concurrence of this movement with the "Great Bufflehead Crash" on 4 November 1940 (Swallow 1941; Finley 2001). Bellrose (1976) remarked that this first wave of migration occurred at "surprisingly similar times" across the northern plains. Erskine (1972) believed that migration peaks were correlated with mean temperatures and the timing of freeze-up, and – lacking the instantaneous advantage we have today of viewing the earth on-line – he illustrated the general weather system that forced mass movements of Buffleheads out of their breeding grounds. An example of this system, the first sustained high pressure system in the Mackenzie Basin, is illustrated by Woo et al. (2007). Because the thermodynamics of freeze-up are a good integrative measure of climate (Menard et al. 2002; Jefferies 2005), the phenology of Bufflehead autumn migrations should be a good proxy indicator of the advance of the zero degree isotherm, and thus of climatic variability.

Buffleheads presumably respond to seasonal changes in light levels, mediated by the pineal gland, such that light levels induce "zugunruhe", or migratory restlessness (Welty 1975). They arrive here two or three days after the average date of freeze-up of their most northerly breeding grounds in central Alaska (Jefferies et al. 2005). Thus, the onset of migration may represent a threshold effect of the mid-October photoperiod, whereas the first major influx in late October may represent a thermodynamic threshold associated with general freeze-up, a reliable indicator of the first significant outflow of arctic air, and the advance of the zero degree isotherm. The exact timing of the first influx is determined by weather patterns and the need for clear nights for celestial navigation, conditions typical of high-pressure air masses, in the aftermath of a front. The earliest influx, beginning 23 October 2004, corresponded to the first snowfall on the prairies. The rapid increase to peak numbers on 30 October 2006 was due to a major incursion of arctic air and a rapid freeze-up throughout the west, whereas the delayed build-up in 2005 was due to warmer than normal conditions, and late freeze-up (Environment Canada 2006*). The first influx was not always marked (e.g., 2001 and 2005), but the last one tends to occur just before Remembrance Day (11 November) and may represent the climatic domain and freeze-up phenology of the interior of British Columbia, and/or the arrival of a different component of the population.

I did not monitor numbers continuously in 2007 but did note influxes on 27 October and 11 November, the latter preceding the first major storm front of what was to become La Nina's infamous winter from hell. This latter influx included a distinctive female of a pair that has returned annually to the same territory for the past three years, so it may be that the breeding pairs are amongst the last to arrive, having re-joined in the interior before their overnight flight. Lack of any clear trend in the male composition of flocks suggests that re-integration of the sexes and pair re-bonding occurs prior to migration, even though I once observed a bachelor flock of two hundred on the Nicola Lake marsh, near Merritt, British Columbia, as late as 6 November 2000.

Evidently the timing of first arrivals and peak autumn movements has not advanced during the latter half of the twentieth century, even though the Mackenzie Basin region has experienced the greatest warming in Canada in the last five decades, by as much as 1.5°C (Woo et al. 2007). However, the temperature increase has occurred only in winter; summer temperatures have shown no trend and freeze-up time has remained consistent (Duguay et al. 2005; Jefferies 2005). Thus, although ice duration has decreased over the last two centuries due to global warming, it is not due to later freeze-up but rather to earlier break-up. If a slight change in air temperature is sufficient to shift freeze-up dates by several weeks, one would expect that the peaks of Bufflehead migration would shift accordingly over decades. In fact the timing of the first influx does not appear to have changed in decades, falling within the average range of freeze-up time in Back Bay, Yellowknife (Menard et. al. 2002).

Menard et al. (2002) found that computer simulations of freeze-up dates were later by six days than actual observations. Undoubtedly, the timing and volume of Bufflehead flights are a more precise and inte-

TABLE 1. First arrivals of Buffleheads on Roberts Bay, 1996–2005.

Year	October	Julian day	Time	Total Number	Number of males
1996	17	291	09:00	6	2

grative measure of freeze-up. The narrow variation found in this study suggests that monitoring of their numbers from certain localities, in conjunction with shore-based observations of freeze-up, would (a) help validate one-dimensional thermodynamic models, (b) add a light-sensitive ecological indicator, representing the advance of the 0°C isotherm, and (c) provide a more meaningful index of climate change across the western boreal region, at minimal cost. This could be achieved through citizen participation.

Long dismissed as amateur natural history, phenology has become popular again with the rise of citizen participation in environmental and ecological monitoring programs. More and more citizens, concerned about the impacts of global warming, are participating in "earth-watch" programs, creating phenological statistics by which to gauge environmental change. Haupt (2006) argued that lay people need to reclaim natural history and become involved in their own biological education. What better way, she suggested, than to keep a diary "phenological awareness immerses us in the rhythmic dimensions of the natural world ... we become engaged, watchful, and increasingly resident."

But a phenological notebook has little meaning unless observations are carried on diligently beyond the typical limited time frame of biological studies; only then can meaningful statistics be generated. Most phenological studies naturally emphasize the early arrival of spring migrants as indicative of a climate change in the northern hemisphere (Cotton 2003); however, the accumulated energy budget of boreal aquatic ecosystems is determined by the switch-off date, tripped by "old Jack Frost," setting the Bufflehead in motion. In a climate of change, the punctual Bufflehead is a comforting constant. *Bucephala exclararet nos.*

Offshore Flight of Buffleheads, *Bucephala albeola*, After Twilight in Winter: An Anti-Predation Tactic?

James K. Finley

10232 Summerset Place, Sidney, British Columbia V8L 4X2 Canada

Finley, James K. 2007. Offshore flight of Buffleheads, *Bucephala albeola*, after twilight in winter: an anti-predation tactic? Canadian Field-Naturalist 121(4): 375-378.

In winter, on Vancouver Island, Buffleheads depart from coastal marine feeding habitat shortly after the onset of civil twilight. This precisely-timed phenomenon may have evolved in response to predation pressure from Peregrine Falcons, *Falco peregrinus*. The dual habitat requirements of Buffleheads in Shoal Harbour Migratory Bird Sanctuary (1931) and Sidney Channel Important Bird Area are to be included within the proposed Gulf Islands National Marine Conservation Area.

Key Words: Bufflehead, *Bucephala albeola*, timing, crepuscular flight, anti-predation, dual habitats, British Columbia.

Time, timing and habitat structure are key elements in the evolution of anti-predation behaviour. Many species' behaviours are synchronized with shifting light levels to reduce the risk of attack. Genetic clocks are set by aeons of predatory pressure.

At least since the Pleistocene, Buffleheads (*Bucephala albeola*) have returned from their interior breeding grounds to limited marine wintering habitat on the east and west coasts of North America (Erskine 1972; Gauthier 1993). A large portion of the western population winters in coastal waters of the Strait of Georgia and Puget Sound (Salish Sea) where they occupy sheltered coves like Shoal Harbour Migratory Bird Sanctuary, on the southeastern coast of Vancouver Island (Dawe 1982*). Established in 1931, the sanctuary includes inter-tidal mudflats that support high densities of benthic invertebrates, prime feeding habitat (when covered with water) for Buffleheads. Buffleheads feed intensively during the day but what they do at night is largely unknown. Here, I document a precisely timed phenomenon, the Bufflehead's offshore flight after twilight.

Methods

This study was conducted from my home observatory in Sidney, British Columbia, overlooking Shoal Harbour Migratory Bird Sanctuary on southeastern Vancouver Island, adjacent to Sidney Channel "Important Bird Area" and the new Gulf Islands National Park Reserve (Figure 1). My bay-window overlooks Roberts Bay, a rich inter-tidal mud flat, prime Bufflehead habitat from mid-October to early May. Monthly surveys of the sanctuary have been conducted since 2000 as part of the Coastal Waterbird Surveys, a citizen-based monitoring initiative of Bird Studies Canada and the Canadian Wildlife Service, Environment Canada (Badzinski et al. 2006).

Casual observations occurred every day between October and May, from my vantage 4-6 m above sea level, with a westerly view such that Buffleheads can be seen in silhouette at dusk, and against background residential lighting. Observations of their departure time (Pacific Standard Time) were recorded opportunistically between January and May in 2000 ($n = 29$), 2004 ($n = 15$), 2005 ($n = 12$) and 2007 ($n = 5$). Typically the flock departed in waves close together and departure time was recorded to the nearest minute. Sometimes, especially toward spring, departure was spread out over several minutes, though the majority of birds typically departed en masse. In such cases, the median departure time, when the majority left, was used in the analyses. Data were entered on a computer spreadsheet along with a table on sunset and twilight times for latitude 48°N (Victoria). Regression analysis was performed with Microsoft Excel software.

Civil twilight is defined when the sun is 3 degrees below the horizon and there is sufficient illumination, in clear conditions, for the average human eye to distinguish terrestrial objects, and the horizon remains distinct (U.S. Naval Observatory website). Nautical twilight occurs when the sun is 6 degrees below the horizon, the general outlines of objects may be distinguishable, and the horizon is indistinct.

Results

The late winter (January to March) population of Buffleheads on Roberts Bay was relatively stable at 130 ± S.D. 33, $n = 16$. Typically, around sunset, these birds began to gather near the southwestern shore, especially around the delta of Mermaid Creek, where they engaged in social activity and preening before coming to a rest, heads tucked, tails erect. During the brief rest period, the flock was often arrayed in lines near shore, facing offshore, with a few alert individuals. Imminent departure was often evident by abrupt alertness of the flock, followed by swimming toward the mouth of the bay. Small groups or pairs sometimes departed in advance of the main movement, but typically, the flock departed close together, about 10–12 minutes after the onset of civil twilight, before the onset of nautical twilight. The slope of the departure regression

line parallels the seasonal advance of civil twilight (Figure 2). One exception fell significantly before the twilight threshold; this occurred on 3 February 2007 when the flock departed 27 minutes earlier than expected.

Discussion

The offshore departure of Buffleheads after civil twilight is a precisely timed phenomenon, presumably set by their genetic clock, and hormonally mediated by the pineal gland (Welty 1975). Undoubtedly some of the variation was due to the effects of cloud cover; a more precise correlation could likely have been obtained if a light meter had been used. Surprisingly, there is no mention of this daily scheduling activity in the literature (Munro 1942; Erskine 1972; Gauthier 1993), nor of similar behaviour in the waterfowl literature, although it is generally recognized that waterfowl tend to fly around sunset. Perhaps their daily flight has been overlooked because most biologists are sitting down to supper and the news, or — maybe more so — because we live by the clock and tend to take such scheduling for granted.

Buffleheads appear to be obligatory nocturnal migrants, famous for their crash on 4 November 1940, caused by unusual weather and artificial lighting conditions in Saskatchewan (Swallow 1941; Erskine 1972; Finley 2001; Eyolfson 2006). Nocturnal migration, timed to coincide with favourable tailwinds and clear skies, may have evolved due to the energetic demands of the Bufflehead's small size and their need to feed during daylight. This physiological factor in long-range migration appears irrelevant to their daily schedule, although in both cases their flight is initiated after sunset. Perhaps their daily offshore flight is an anti-predation tactic.

Three predators, River Otters, *Enhydra lutra*, Peregrine Falcons, *Falco peregrinus*, and Bald Eagles, *Haliaeetus leucocephalus*, prey on Buffleheads on their west coast wintering grounds. Buffleheads are highly vigilant for otters, and distinguish them from Harbour Seals (*Phoca vitulina*). Most successful predation attempts that I've observed have involved otters, often a couple of times each season, usually in rough seas, and at any time of day though perhaps more frequently in low light conditions. If Buffleheads are more vulnerable to otters in low light, one would expect that they would depart from coastal waters well before twilight.

All other successful attempts have involved the resident pair of eagles, which overfly the sanctuary throughout the day. Bald Eagles take the occasional Bufflehead by either surprising them, or hovering and forcing them to tire; however, this is a demanding strategy, not often seen. Though mildly alert to their flights, Bufflehead do not normally take evasive action unlike the resident Wigeon (*Anas americana*). Yet eagles can be effective predators; just this past December, the pair, working in tandem, took two in succession within an hour. It seems that they take primarily juveniles and weak birds,

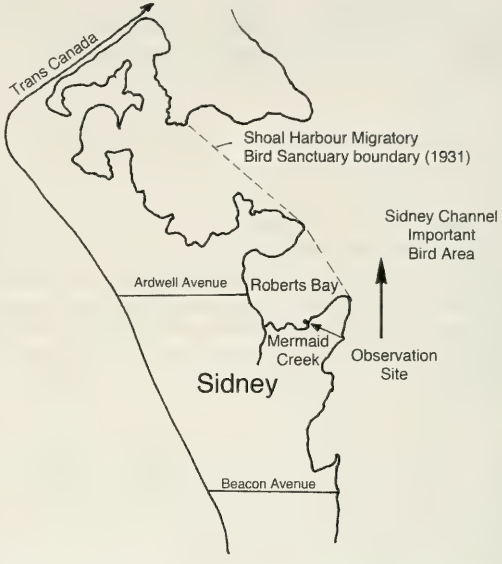

FIGURE 1. Shoal Harbour Migratory Bird Sanctuary in Sidney by the Salish Sea, prime Bufflehead habitat in winter.

perhaps more often during the coldest days of midwinter, and at any time of day. Only once have I observed an eagle take a drake, but it happened under unusual circumstances involving a Peregrine Falcon.

In contrast to their relaxed vigilance toward potential eagle predation, Buffleheads show a heightened alertness to peregrines. On the occasion just mentioned, a peregrine stooped on a flock, causing a panic of diving, and with "split-second" timing, an eagle, that had evidently anticipated the reaction, launched itself from its fir snag and snatched a surfacing drake. Although I recall only a handful of hazings and unsuccessful predation attempts over the years, I suspect that peregrines might be the driving force behind the Bufflehead's precise departure time. This speculation is based on two anecdotes.

The first occurred on 24 November 2000, when a peregrine passed over the bay just before dusk, causing the Buffleheads to remain highly alert, close in, obscured in the shadows of the south shore. When forced to take flight by a pedestrian just before the end of civil twilight, they did so hesitantly and in a notably chaotic "crash-diving" maneuver. At this time the peregrine stooped, missed, and continued pursuing individuals into the darkness. A few Buffleheads returned near shore and remained until it was too dark for me to detect them. I'd seen the Bufflehead's crash-diving evasive tactics before, though not in the presence of a predator. Evidently it was a practised procedure, like the orchestrated flight drills of the Dunlin (*Calidris alpina*) on the Fraser River delta (Dekker and Ydenberg 2004). The second anecdote happened to be my last data entry (3 February 2007) in

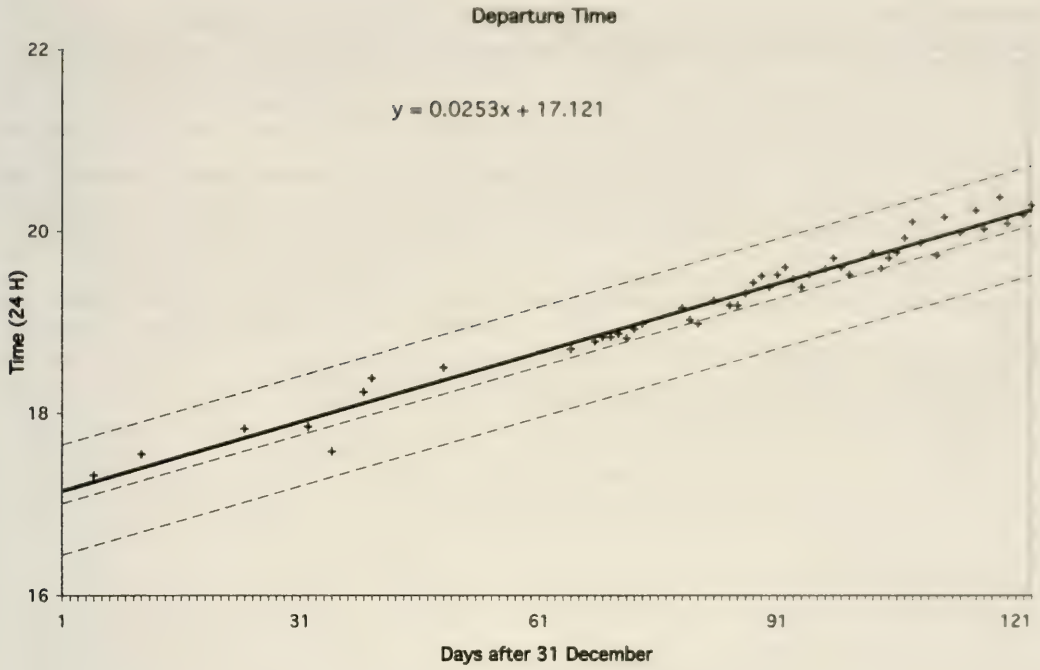

FIGURE 2. Evening departure times of Buffleheads from Shoal Harbour Migratory Bird Sanctuary, January to May 2000-2007. The single exception before civil twilight involved anti-predator maneuvers. The upper dashed line is nautical twilight, the middle is civil twilights, and the lower is sunset.

Figure 2, the only data point to fall before civil twilight and it was one of the rare occasions when they showed evasive flight tactics. Perhaps it was a practice procedure or maybe they sensed a peregrine.

So why do they depart so precisely after twilight? Once aptly called the Duck Hawk, the peregrine is known to be able to hunt in low light levels, and to take crepuscular species such as the Sora (*Porzana carolina*; Nero 2000) and bats. The timing may represent the peregrine's threshold for effective light levels in which to hunt. Peregrines were once more abundant and presumably a much greater threat over eons. Paine et al. (1990) have shown that their recovery has had a marked influence on the structure and integrity of a seabird colony in nearby Washington State. And why, I wonder, do the Buffleheads always depart from one side of the bay? At first I assumed this choice was because the south side was in the lee and around the delta of Mermaid Creek, but now wonder whether it might have more to do with it being on the shaded side of the bay, and their flight trajectory into the darkest horizon within the limits of nautical twilight, less than two feet off the black water, like a Petit Garrot or "Shotbolt".

Although it is thought that Bufflehead populations are not limited by predation (Erskine 1972), this study suggests that predation may strongly shape their behaviour and habitat choice. Just because predation is seldom observed, does not mean that it is not operating in powerful and subtle ways. Although predation pressure and light thresholds might determine the schedule of departures, their daily commute between nocturnal offshore roosting habitat and essential feeding habitat may have evolved due to a complex of other factors.

Where do the Buffleheads go at night? Not far, I believe. On two occasions I've seen some of them land at dusk in adjacent channels of the Gulf Islands, including Sidney Channel "Important Bird Area", a UNESCO-designated site of international importance. This area, including Shoal Harbour Migratory Bird Sanctuary, is presently being evaluated as part of a proposed National Marine Conservation Area. Thus the dual habitat requirements of Buffleheads may be included within a world view.

Diets of Overwintering Caribou, *Rangifer tarandus*, Track Decadal Changes in Arctic Tundra Vegetation

Joly, Kyle, M. Jeanie Cole, and Randi R. Jandt. 2007. Diets of overwintering Caribou, *Rangifer tarandus*, track decadal changes in Arctic tundra vegetation. Canadian Field-Naturalist 121(4): 379-383.

We compared winter diets of Western Arctic Herd Caribou (*Rangifer tarandus*) from 1995/1996 and 2005 using microhistological fecal analysis on samples collected at paired permanent vegetation transects. Changes in the diets of Caribou followed the same trends as vegetative changes documented in long-term studies in northwestern Alaska. Lichens were significantly less prevalent on the landscape and in the winter diets of Caribou between 1995/1996 and 2005, while graminoids (grasses and sedges) were significantly more prevalent. Dramatic changes are forecasted for Arctic ecosystems under global warming scenarios which may continue the trend of declining lichens in northwestern Alaska and in the diet of Western Arctic Herd Caribou. The question of whether or not the altered diet will affect the population dynamics of this herd remains unresolved.

Key Words: Caribou, *Rangifer tarandus*, diet, fecal analysis, climate change, habitat, Western Arctic Herd.

The Western Arctic Herd (WAH), with nearly 500 000 Caribou (*Rangifer tarandus*) as of 2003, is currently one of the largest in the world. Population level records of the herd date back to 1970 when the herd was estimated to be 242 000 Caribou (Dau 2005a). The WAH crashed between 1970 and 1976, falling to 75 000 Caribou (Dau 2005a). It rebounded quickly from this population low, growing at an annual rate of about 13% for more than a decade and reached 416 000 Caribou in 1990 (Dau 2005a). Growth has continued, albeit at a more measured 1% average annual growth rate, reaching 490 000 in 2003 (Dau 2005a). The WAH is an important subsistence resource for approximately 30 villages in northwestern Alaska (Dau 2005a) which harvest nearly 500 000 kg of meat from this herd annually (Valkenburg 1994). Changes to the range on which this herd depends is therefore a subject of interest to the inhabitants of the region, sport hunters, wildlife enthusiasts and land managers. Our goal was to monitor changes in the vegetative characteristics of the herd's winter range, quantify the diets of Caribou utilizing this range, and track changes that have occurred since the previous decade.

The effects of global climate change are currently being expressed in the Arctic. Already documented are warming temperatures, melting glaciers, reduction of pack ice extent, shrinking lakes, and alteration of vegetative communities (Hansen et al. 1999; Serreze et al. 2000; Sturm et al. 2001; Smith et al. 2005). In terms of arctic vegetation specifically, lichen abundance is predicted to decline while vascular shrubs and graminoids (grasses and sedges) may increase (Chapin et al. 1995; Cornelissen et al. 2001; Walker et al. 2006). Though Caribou grazing and trampling have been implicated as major factors in reduced lichen abundance (Moser et al. 1979; Messier et al. 1988; Arseneault et al. 1997; Joly et al. 2007b), climate change may further exacerbate declines. Lichens are thought to be a critical component of the winter diet of large, migratory herds in northern North America (White et al. 1981; Klein 1991). Poor winter range conditions can affect body condition, fetal growth, calf birth weights, milk production, and calf growth rates (White 1983; Parker et al. 2005). Declines in these vital signs could result in reduced herd productivity; therefore, changes in vegetation has the potential to affect Caribou populations and people who depend on them.

Methods

Joly et al. (2007b) investigated 25 permanent vegetation transects, originally deployed in 1981, in 1995 and 1996 (1995/1996) and then reexamined them in 2005. All transects were located in and around the Buckland River valley, which is entirely within the core winter range of the WAH in northwestern Alaska, USA (Dau 2005a; Joly et al. 2007a). Joly et al. (2007b) laid out a sampling frame (1.0 × 0.5 m) every 4 m along the 50-m transect for a total of 12 frames per transect. The frame was strung every 10 cm along both axes, which created 50 intercepts. The first species observed under the intercept was recorded and a percent cover was derived. Each species was assigned to one of following categories: lichen, graminoid, moss, shrub, or forb (see Joly et al. 2007b for more details). Un-vegetated observations (e.g., rocks) were assigned to a different category.

We collected composite fecal samples at 24 of these same transects both in 1995/1996 and in 2005. At one

TABLE 1. Changing percent cover of various vegetative categories comprising the core winter range of the Western Arctic Herd, northwestern Alaska, USA from 1995/1996 and 2005 (adapted from Joly et al. 2007b). Note that percentages do not tally to 100% because the un-vegetated class is not reported here.

Class	1995/1996	2005	Change	P	T	df
Lichens	16.8	12.5	–	0.004	3.21	24
Graminoids	25.3	31.9	+	0.001	4.39	24
Moss	5.9	6.1	/	0.673	0.43	24
Shrubs	30.1	32.8	+	0.045	2.12	24
Forbs	5.9	3.9	–	0.001	3.86	24

TABLE 2. Changing percentage of various vegetative categories in the (uncorrected) diets of Caribou in the Western Arctic Herd, northwestern Alaska, USA from 1995/1996 and 2005.

Class	1995/1996	2005	Change	P	T	df
Lichens	58.5	50.6	–	0.001	3.73	23
Graminoids	15.0	21.6	+	0.002	3.53	23
Moss	16.1	14.5	/	0.351	0.95	23
Shrubs	7.2	8.6	/	0.169	1.42	23
Forbs	3.2	4.5	/	0.155	1.47	23

of the 25 transects we were unable to locate enough samples to conduct analyses. Each composite sample contained about 20 winter (based on form and herd distribution) fecal pellets collected from different pellet groups – one pellet per group. In a few cases, when 20 individual pellet groups were not available, we took two pellets from each group. The samples were frozen and then shipped to a laboratory (see Acknowledgments) for composition analysis. All samples from both sampling periods were analyzed by the same technician during the same session to reduce potential sources of error (see Russell et al. 1993). The relative density of plant fragments was based on 100 fields per sample.

The uncorrected results were compared to changes in vegetative cover determined from the permanent transects. The uncorrected fecal analysis results provided estimates of diet composition but did not provide proportions of ingested diet (Boertje et al. 1985; Russell et al. 1993). Unfortunately, a large percentage (> 80%) of the shrub particles were classified as "Other" or "Unknown", so we were not able to determine if they should be classified as evergreen or deciduous shrubs. Therefore we were unable to apply Russell et al.'s (1993) correction factor for digestibility. Paired t-tests were employed to identify significant changes in percent cover and diet between 1995/1996 and 2005. We calculated Ivlev's index of selectivity (Ivlev 1961) using the formula: (U-A) / (U+A), where U (utilization) was the amount of a vegetation type found in the fecal matter and A (availability) was the percent cover of that type found on the paired transect.

Results

The permanent vegetation transects indicated changes in vegetation from 1995/1996 to 2005 in the winter range of the WAH. Significant declines in lichen abundance were noted, while both graminoids and shrubs increased during this time period (Table 1; Joly et al. 2007b).

The changes in vegetative cover were mirrored by changes in the paired fecal composition of WAH Caribou between 1995/1996 and 2005 (Table 2). The proportion of lichen found in the fecal pellets declined significantly ($T = 3.73$, $P < 0.001$, $df = 23$), while the proportion of graminoids increased ($T = 3.53$, $P < 0.0021$, $df = 23$). The mean proportion of *Cladina* spp. declined from 21.8% to 15.2% from 1995/1996 to 2005 ($T = 4.71$, $P < 0.001$, $df = 23$). This decline in *Cladina* spp. represented 84% of the decline in overall lichen in fecal matter over this time period. There were no significant differences in the proportion of *Cetraria* spp., *Cladonia* spp., or non-preferred lichens (e.g., *Alectoria* spp., *Bryoria* spp., *Peltigera* spp., etc.) between 1995/1996 and 2005. There were no significant differences in the other vegetative classes (Table 2).

Lichens and mosses were found in the fecal matter of WAH Caribou more than they were present in the environment in both 1995/1996 and 2005 (Figure 1). Ivlev's (1961) index of selectivity increased for lichens between 1995/1996 and 2005, despite declines in lichen availability. The index decreased for mosses as its availability declined (Figure 1). Graminoids and shrubs were more common on the landscape than in the fecal matter of Caribou in both 1995/1996 and

FIGURE 1. Ivlev's index of selectivity for Caribou utilizing different vegetative categories on the winter range of the Western Arctic Herd, northwestern Alaska, USA. Light-colored bars represent data from 1995/1996 and the dark bars from 2005. An index of 0 would occur when the amount of that category was found in equal percentages in the fecal matter and along paired permanent vegetation transects. Ratios > 0 reveal vegetation types that were greater in the diet than found on the landscape. Ratios < 0 reveal vegetation types that were less prevalent in fecal matter than on the landscape.

2005 (Figure 1). Ivlev's (1961) index of selectivity declined between 1995/1996 and 2005 in the face of increasing availability of these vegetation types.

Discussion

Lichen content in the winter diet of Caribou has been reported to be from 62 – 69% (Thompson and McCourt 1981; Boertje 1984; Boertje et al. 1985; Russell et al. 1993). While our results show somewhat lower lichen content (51 – 59%), we were not able to apply correction factors to account for differential rate of digestibility among vegetation types. Lichen content is typically under-represented without correction factors (Russell et al. 1993), so our results are likely similar to these previous studies (though see Boertje et al. 1985).

We know of no other studies that have tracked the diets of Caribou over a decade and directly related detailed vegetative cover surveys to dietary analyses. Our results show that the recent winter diet of WAH Caribou contains less lichen and more graminoids than in the past, tracking changes in vegetative cover from 1995/1996 to 2005 reported by Joly et al. (2007b). The percent of lichen in the fecal matter was 3.5 – 4 times greater than the percent of lichen cover in the environment, suggestive of selection. Caribou used areas of high lichen cover more than other areas (Joly et al. 2007b). The significant reduction of *Cladina* spp. in the fecal matter between time periods was also reflected in declines of primary forage lichen on the landscape (Joly et al. 2007b). Grazing was likely a factor that drove the decline in lichen in northwest Alaska (Joly et al. 2007b). It may take a couple of decades for lichens to recover from intense grazing, barring further disturbance (Henry and Gunn 1990).

Shrubs are significantly increasing in the Arctic (Sturm et al. 2001; Joly et al. 2007b); however, we did not detect a corresponding increase in shrubs in the diet of WAH Caribou. Shrub expansion could have negative impacts on individual Caribou energetics and multiplier effects on the herd (see Lawler and White 2006). Other researchers have reported increased moss cover where Caribou range has been heavily grazed (Klein 1987; van der Wal 2006), but changes in moss cover were not detected within the range of the WAH during this time period (Joly et al. 2007b). Mosses were present in the fecal matter in greater percentages than were found on the landscape; however we believe this is due to its low digestibility rather than Caribou selecting for this forage type (Boertje et al. 1985).

Climate warming is another factor that has been implicated in declining lichen cover within the range of the WAH (Joly et al. 2007b). Fire activity is strongly correlated with warm summer temperatures in Alaska and Canada (Duffy et al. 2005; Kasischke and Turetsky 2006). The frequency and extent of fires is predicted to increase due to global warming (Rupp et al. 2000; McCoy and Burn 2005). Lichens within the range of the WAH are slow to recover from wildfire, often taking many decades to recover to initial levels (Arseneault et al. 1997; Jandt et al. 2008). Overwintering Caribou are known to avoid burned areas in both tundra and boreal forest, in northwest Alaska, for up to 55 years (Joly et al. 2007a). Lack of lichens

in these areas has been hypothesized to be a reason for this avoidance though other factors have been suggested (see review by Klein 1982).

Lichen cover has been declining in the study area since 1981 (Joly et al. 2007b). Potential outcomes of continued declines in lichen cover in winter range include range shifts and population-level effects (Ferguson et al. 2001; Joly et al. 2007b). Caribou nutritional status should not be assessed based on lichen abundance alone (Boertje 1990). Studies in the high Arctic studies have shown that Caribou can be less reliant on lichens (Thomas and Edmonds, 1983; Adamczewski et al. 1988). However, these Caribou do not face the predatory pressure and migratory expense that WAH Caribou do and also differ phenotypically. Additional differences between these types include greater ability of the high Arctic Caribou to store fat and digest graminoids and mosses (Tyler 1987). Large, migratory herds of barren-ground Caribou, like the WAH, are thought to be reliant on abundant terricolous lichens (White et al. 1981; Klein 1991; Heggeberget et al. 2002). Nevertheless, it has been suggested that Caribou may not be negatively affected by a change from a lichen-rich diet to a graminoid-rich diet as ecosystems transition to graminoid-dominated states (van der Wal 2006).

Adult survival rates would be the least sensitive population parameter to potential declines in nutritional status, so biologists and managers should monitor pregnancy rates and calf to cow ratios to detect early signs of nutritional stress. Declines in these parameters may imply that the nutritional status of the herd is declining due to poor range conditions and that the transition to a graminoid diet may impact the herd. Recruitment in the WAH has been slowly declining (Dau 2005a) and the most recent photo-census (2007) revealed a 20% decline in the herd (J. Dau, personal communication), which may be incipient indications of the importance of lichens to this herd. Predation is not likely a major factor in these declines with the herd size being so large and predator densities relatively low (Ballard et al. 1997; Haskell and Ballard 2007), though density-independent icing events may be a factor (Dau 2005b). Although the debate over the relative importance of lichens in the winter diet of Caribou remains unresolved, our results reveal that WAH Caribou use lichens extensively in the winter despite their declining abundance on the landscape in northwestern Alaska.

Acknowledgments

Fecal analysis was conducted by the Wildlife Habitat Nutrition Analysis Laboratory at Washington State University, Pullman, Washington, USA. R. Meyers, (retired) Bureau of Land Management, was an integral member of the research group during both study periods. We thank J. Lawler, D. Spalinger, J. Welker, S. Wilson and two anonymous CFN reviewers for providing recommendations for substantially improving previous drafts of this manuscript.

An Analysis of the Historical Records for the Native Mammalian Fauna of Prince Edward Island

DOUGLAS G. SOBEY

Research Associate, Institute of Island Studies, University of Prince Edward Island, Charlottetown, Prince Edward Island C1A 4P3 Canada

Summer address: P.O. Box 4004, Bedeque, Prince Edward Island C0B 1C0 Canada

Formerly: School of Applied Biological Sciences, University of Ulster, Jordanstown, Northern Ireland, BT37 0QB United Kingdom

Sobey, D. G. 2007. An analysis of the historical records for the native mammalian fauna of Prince Edward Island. Canadian Field-Naturalist 121(4): 384-396.

A search was carried out for historical records, both published and unpublished, that make reference to the native mammalian fauna of Prince Edward Island. Based on documents dating from 1721 to 1890, a comprehensive list of the records for the native mammals of the island has been compiled. Among the new information found is evidence for the presence of the Grey Wolf (as well as the Woodland Caribou) at the time of the first French settlement in 1720, and for the absence of the Beaver and Moose. Historical information has been assembled on the abundance and food-chain relationships of each of the mammalian species, as well as on their interactions with the European population, including the attitudes of the new settlers towards each species. The records indicate that seven of the mammals were extirpated: the Grey Wolf, American Black Bear, American Marten, River Otter, Canada Lynx, Atlantic Walrus and Woodland Caribou. All of these extirpations were due to the activities of the European population, with the attitudes of the settlers contributing to four of them: an indifference to the survival of the otter and Marten, and a direct hostility to the bear and lynx (due to their predation on livestock), leading to the payment of bounties.

Key Words: historical records of mammals, mammalian fauna, Prince Edward Island, Grey Wolf, American Marten, Atlantic Walrus, Woodland Caribou, Moose, Beaver.

At the time of the first European settlement on Prince Edward Island in 1720, the island supported a varied mammalian fauna. In the course of the next 180 years, the native fauna was to become greatly reduced, with six terrestrial species (five of them predators) and one marine mammal being eliminated from the system. Despite an awareness of this general picture (e.g., Clark 1959), the many historical accounts relating to the island's native mammalian fauna have never been subjected to comprehensive analysis. It was hoped that a detailed examination of the records would not only reveal what species were present when European settlement began, but also yield information on the interactions between the native fauna and the European population, including the extent to which the fauna contributed to the food supply of the human population and to any fur-trade economy that developed, as well as an understanding of the factors that led to the extirpation of most of the fur-bearing predators. Initially, my aim was to examine only the records for the terrestrial fauna, though later the pinnipeds occurring in island waters (i.e., the seals and the walrus) were also included.

The historical context

Prince Edward Island (known as Île Saint-Jean to the French) was "discovered" by Jacques Cartier in 1534. However, historical accounts in any significant numbers only begin to occur from 1720, the year of the arrival of some 250 colonists from France. (See Clark (1959) for an in-depth study of the island's historical geography.) Prior to the arrival of the French, aboriginal use by the Mi'kmaq appears to have been confined to the summer period, as part of their seasonal migration to the coastal areas of the Maritimes, though with the establishment of the first French settlement some of the Mi'kmaq began to spend the whole year. The French population grew slowly, so that by 1748 there were only 735 persons. However, numbers then rose sharply, reaching almost 5000 by 1758, due to the arrival of Acadian refugees from the Bay of Fundy area on account of the political unrest and deportations occurring in Nova Scotia. After the fall of Louisbourg in 1758 almost all of the Acadian population was deported to France by the British military authorities, or fled to the mainland, leaving only a few hundred refugees. From the 1770s British settlement proceeded slowly, with by 1805 the population reaching only 6957. However, it then began to grow exponentially, reaching 71 000 by 1855, when immigration from the British Isles began to end. Even so, natural growth continued, with numbers peaking at 109 000 in 1891 (Clark 1959). This increase in the human population was associated with a decrease in the area forested, and by 1935 only 32% of the land area still had a forest cover (Glen 1997).

Prior to European settlement virtually all of the island's land area of some 5750 km^2 had been covered by old-growth forest, with the predominant forest-type

TABLE 1. Twenty-one lists of the mammals of Prince Edward Island made by different recorders between 1721 and 1890. The lists are in chronological order, with the names of the recorders given below the table; these are fully referenced at the end of the paper. See the main text for the identification of the species. (E = extirpated – i.e., reported as either no longer occurring on the island, or the evidence is for the past occurrence only; A = reported as absent from the island.) [*]

* List 19 is a composite list assembled from the responses of eighteen men to several questions on the mammals occurring on the island in their "young days", contained in a questionnaire sent out in 1876 to the "oldest inhabitants" by a Charlottetown historical committee; list 20 has been put together from anecdotes on the island's native fauna contained in a series of nineteen articles on pioneer life published in 1877 and 1878 in the *Presbyterian and Evangelical Protestant Union*.

particularly in the central part, consisting of hardwood forest in which American Beech (*Fagus grandifolia*) especially, but also Sugar Maple (*Acer saccharinum*) and Yellow Birch (*Betula alleghaniensis*) predominated (Sobey and Glen 2002, 2004; Sobey 2006). In the eastern and western parts, where there was a higher proportion of poorly drained soils, other forest-types occurred, especially a type of "swamp" woodland, containing Red Maple (*Acer rubrum*), Eastern White-cedar (*Thuja occidentalis*), Black Ash (*Fraxinus nigra*) and American Elm (*Ulmus americana*), as well as a boreal forest-type in which Black Spruce (*Picea mariana*) predominated along with a minority element of Tamarack (*Larix laricina*). The upland hardwood forest in particular was subjected to large-scale clearance for agriculture, with any remnants (often in the form of farm woodlots), undergoing considerable change due to the continual harvesting of selected species for timber and firewood. As well, in all forest-types there were the damaging effects of the ubiquitous forest-fires associated with forest clearance. The removal of this old-growth forest and the alteration of that which remained would have had considerable consequences for the island's mammalian fauna.

Results

From the beginning of European settlement in 1720 there is a regular flow of relevant documents from the French (1720-1758), British (1758-1873) and post-Confederation periods (1873 to *c.*1900). These comprise both published books, such as immigrants' handbooks and travel accounts (most of which were

† See List-makers cited in Table 1 after Literature Cited.

available in the P.E.I. Collection of the Robertson Library of the University of Prince Edward Island), and unpublished documents, including government records and private journals, many of which were housed in the Provincial Archives and Public Records Office in Charlottetown (PEI PARO). Some 58 documents were found that make reference to one or more of the native mammals of the island – these are fully reported in Sobey (2002, 2006). Especially informative are those records where the writer constructed a *list* of the mammals of the island: twenty-one such lists have been assembled in Table 1. Four come from the French period (all based on observations made between 1720 and 1752) and seventeen from the British and post-Confederation periods. Many of these list-makers also made short comments on the abundance and/or ecology of some or all of the mammals, as well as on their relations with the human population.

The lists range from four recorders who mention only six species, to one listing twenty-one. All but four of the list-makers appear to have been resident on the island for at least a year, and most for many years. The exceptions are Franquet (1751†), Pichon (1760†), Walsh (1803†) and Rowan (1876†), who spent from seventeen days to a few months. However, given the elusive nature of most of the mammals, it is unlikely that even the resident recorders would have seen every animal they listed, and it is especially likely that animals that were known to have occurred in the past would have continued to have been listed for some time after their extirpation. Also, there is a likelihood that some of what they record may derive not from their own observations, or even from the anecdotal experience of other island residents, but from general written sources from elsewhere.

Table 1 indicates that, collectively, there is a bias in the selection of the animals recorded. The smaller mammals (the shrews, bats and rodents) were either ignored, or else were treated generically, except by a few of the late nineteenth century "scientific" recorders, such as Sutherland (1861†) and Bain (1890†), whereas a greater coverage was given to those mammals considered "useful" to the human population; i.e., as a source of food or products such as furs. Also, some of the animals received greater attention because of their predation on the settlers' livestock and poultry. The records for each mammal are presented separately below, with the nomenclature and order following that of Scott and Hebda (2004).

Shrews

The Atlantic Canada Conservation Data Centre (ACCDC 2008*) lists five species of shrew as currently occurring on Prince Edward Island: the Masked Shrew (*Sorex cinereus*), Water Shrew (*Sorex palustris*), Smoky Shrew (*Sorex fumeus*), Pigmy Shrew (*Sorex hoyi*), and Northern Short-tailed Shrew (*Blarina brevicauda*). However, the only historical records for the presence of shrews are those of Sutherland (1861†) and Bain (1890†), who recorded the presence of what they called the "shrew mouse" and "shrew mole", respectively (Table 1), both mentioning that it fed on insects.

Bats

ACCDC (2008*) lists four species of bat for Prince Edward Island: the Little Brown Bat (*Myotis lucifugus*), Northern Long-eared Bat (*Myotis septentrionalis*), Hoary Bat (*Lasiurus cinereus*), and Eastern Red Bat (*Lasiurus borealis*). For the Eastern Red Bat there is a sight record only. Not surprisingly, the four recorders who noted the presence of bats (Table 1) listed them as if only one species were present. All four recorders indicated that bats were common during the summer, and Bain (1890†) said that they "[hid] away in some secure cranny in buildings or in a hollow tree".

Grey Wolf

The only certain record for the Grey Wolf (*Canis lupus*) is that of La Ronde (1721†), who said that there were wolves "of a prodigious size" on the island. That he also added that he was sending a wolf pelt back to France from the island, both supports his record and indicates they were vulnerable to the presence of the newly arrived Europeans, though it is not impossible that it was the Mi'kmaq who were responsible for the kill. Since there is no further mention of the presence of wolves in eighteenth century records, it is possible that the Grey Wolf was extirpated shortly after settlement began, or else moved across the ice to the mainland. It is thus surprising that there are a couple of late post-Confederation mentions of its presence ([Lawson] 1877-1878†; Bain 1890†), both of which report, on the basis of anecdotal and second-hand information of unknown date, wolves as transient visitors. What Bain (1890†) says is that "wolves have been known to cross the Northumberland Strait on the ice and visit the Island". If this ever occurred, it was likely to have been long before the 1890s when the island was at the peak of European settlement and forest clearance, and when according to Lohr and Ballard (1996) the Grey Wolf was very scarce on the mainland.

Red Fox

The Red Fox (*Vulpes vulpes*) occurs in all twenty-one lists (Table 1), with several recorders noting it as common (MacGregor 1828†; Sutherland 1861†; Anonymous 1876†; Bain 1890†). Others noted the presence of different colour phases (e.g., Franquet 1751†; [Cambridge] *c.*1796†; Stewart 1806†): red, black, and silver-grey are the most frequently listed, though all noted that the red phase was by far the predominant. A fox fur of any colour seems to have had some value, though it was the blacks and silver-greys that were especially sought after. Stewart (1806†) said that the number of foxes caught on the island was

"very considerable", while the means of catching them included steel traps and shooting (Stewart 1806†; MacGregor 1828†; Hill 1839†). There are varying opinions on the fox's pest status, several persons recording that it occasionally took poultry, though they differ as to whether it attacked sheep (Stewart 1806†; MacGregor 1828†; Johnstone 1822†). As for their natural food, according to Bain (1890†), it was "young birds and quadrupeds", while MacGregor (1828†) more vaguely mentions that they fed "in the woods or along the shore".

Black Bear

The American Black Bear (*Ursus americanus*) was recorded by nineteen of the twenty-one list-makers (Table 1) and during the British period several recorders devoted a paragraph or more to it, and especially to its interactions with the human population. It would seem that in the early years bears were abundant on the island: for example, in February 1780 the ensign of a visiting regiment ([Ritter] 1780††) recorded that his soldiers were shooting the bears that came near their huts at Charlottetown, while the proprietor Shuttleworth (1793†) reported that where he lived (near St. Peters Bay) bears "swarmed to a degree that [he] could not have believed", and the visiting bishop Plessis (1812††) said "they are seen in greater numbers than one would expect". However, just ten years later Johnstone (1822†) noted that they were "decreasing in numbers greatly", with the "few of them yet in the woods" being only "seen occasionally by the inhabitants". There are similar comments on its decline by MacGregor (1828†), Bagster (1861†) and Anonymous (1876†), with by the end of the century, Bain (1890†) saying that bears were restricted to "the large wooded tracts" in the east and west of the island. Since, beginning as early as Stewart in 1806, several writers were predicting the Black Bear's impending extirpation, it comes as a surprise that the last recorded bear on Prince Edward Island was shot in 1927 (Hornby 1987).

There was an almost total antipathy to the Bear, largely due to its habit of killing livestock, a practice not discouraged by the fact that in new settlements, farm animals were let loose in the woods (e.g., Stewart 1806†). Sheep are the most frequently mentioned as being taken (by fourteen recorders), followed by pigs and cattle (by eight and nine recorders respectively). Not surprisingly, these attacks seem to have been greater in the early years, Stewart (1806†) recording that "the quantity of black cattle, sheep and hogs destroyed by them annually is considerable". However, later reports (Johnstone 1822†; MacGregor 1828†) suggest that such predation was only occasional, presumably due to the decline in the number of bears. Bain (1890†) also reported that bears could do "great damage" by feeding on oats in the field.

In terms of their danger to people, the general consensus was that bears avoided humans and only attacked when either threatened or with their cubs (Stewart 1806†; MacGregor 1828†; Bagster 1861†; Sutherland 1861†; Anonymous 1876†; Bain 1890†). All the same, it was the perception of the Black Bear as a *potential* danger, based on perhaps a few incidents, which greatly added to the human antipathy towards them. In fact, even in the early years the list of their "evils" was considered so great that an official extermination program was instituted in the 1790s (Vass 1987). This involved the payment of a bounty of 15 shillings per bear (a large sum at the time), and remained in effect until the 1860s. Vass (1987) estimated that between 1820 and 1861 bounties were paid on over a thousand bears. Apart from the bounty, the Black Bear provided other resources to some of the island's human population: its skin was especially valuable (MacGregor 1828†; Sutherland 1861†), and it was also a source of food for some, especially the Mi'kmaq (Johnstone 1822†), and the Acadians during their refugee years (Holland 1765†; Patterson 1770†), and seemingly for others as well (Sutherland 1861†; Bagster 1861†).

We are told a little about the Black Bear's natural diet: several writers noted that it fed primarily on "berries", "wild fruits" and "small shrubs", as well as on insects (ant hills and grubs in old fallen trees were favourite foods), and on smelts in the spring (Stewart 1806†; MacGregor 1828†; Sutherland 1861†; [Lawson] 1877-1878†; Bain 1890†). Curiously, none of the recorders mention them feeding on the island's abundant beech mast resource, for which there is evidence from elsewhere (e.g., Vass 1987; Telfer 2004).

Marten

The American Marten (*Martes americana*) occurs in nineteen of the twenty-one lists (Table 1). The only comments on its abundance are Stewart's (1806†) that it was "a very shy little animal, seldom seen in the woods, though some years in great abundance", and Sutherland's (1861†) inclusion of it among those mustelids that were "much more numerous" than the "comparatively scarce" otter. Bain (1890†) noted that it was "a woodland animal nesting in hollow trees and feeding on birds and small animals", and they also appear to have fed on voles during the "mouse plagues" (MacLeod 1876††). None of the recorders seemed aware of its approaching extirpation, for at some period, perhaps even in the late nineteenth century, the Marten became extinct on the island. As for its fur, several recorders commented on its value (e.g., MacGregor 1828†; Hill 1839†; Sutherland 1861†), while Holland (1765†) reported that martens were one of those animals that the refugee Acadians were compelled to use as food after the deportation of most of the French population in 1758.

Weasel

The first record for the presence of the Short-tailed Weasel or Ermine (*Mustela erminea*) on the island is that of Stewart (1806†) (Table 1). In fact, he treated it as two separate species, as did several later recorders. One of these he called the "weasel", which he said was "common" and "often destructive amongst poultry", while the other, the "ermine", was "uncommon" and made its nest inside fallen trees. MacGregor (1828†), continuing this distinction, said that "weasels and ermines were not common", as did Bagster (1861†), who, however, considered only one species to be present, which he called the ermine or "white weasel". In the same year Sutherland (1861†), still listing it as two separate species, said they were "much more numerous" than the otter, and that their fur "brings a fair price", which is the only comment on its value as a fur-bearing animal. Apart from Stewart (1806†) above, no other author implies that it was a pest, and Bain's (1890†) comment that it was "frequently seen about farmsteads where it comes in search of mice", indicates that it was then not uncommon, and at the same viewed as an assistant in mouse control.

Mink

The American Mink (*Mustela vison*) is first recorded in the French period (Franquet 1751†) and thereafter appears in thirteen of the British period lists (Table 1). The only comment on its abundance is Sutherland's (1861†) that it was much more numerous than the "comparatively scarce" otter. Its habitat associations are encompassed in Stewart's (1806†) description of it as "amphibious", while Bain (1890†) used the term "semi-aquatic", saying that it fed on fish and frogs, as well as on "small land animals". Bagster (1861†) also noted fish as its main food item. In terms of its pest status, both Stewart (1806†) and Bain (1890†) recorded that it took poultry and eggs, while Bagster (1861†) said that it also caused damage by burrowing into mill-dams. Several recorders reported its fur to be of value (Stewart 1806†; MacGregor 1828†; Hill 1839†; Sutherland 1861†; Bain 1890†), though Bagster (1861†) said it varied in quality.

Otter

The River Otter (*Lontra canadensis*) makes an appearance in seventeen of the twenty-one lists, beginning with that of La Ronde in 1721 (Table 1). Due to the high quality and monetary value of its fur (Stewart 1806†; MacGregor 1828†; Hill 1839†; Bagster 1861†; Sutherland 1861†; Bain 1890†), in the British period the otter was under considerable pressure from trapping, and such trapping had also been recorded in the French period (Roma 1750†; Pichon 1760†). As early as 1806 Stewart's use of the past tense: "they have been very plenty on the island" implies they were in decline, despite his adding that "they are still caught in considerable numbers". By 1861 both Bagster and Sutherland could note that otters were "getting very scarce" and "comparatively scarce", respectively, Sutherland attributing this to habitat loss, or as he put it, "the increasing occupation of the country". Bain in 1890, by which time it must have been even scarcer, if not already extirpated, makes no comment at all on its abundance, instead noting that it lived in ponds and streams feeding on fish, and that when these failed, "it will attack lambs and poultry". Holland (1765†) noted that it was among those animals hunted by the refugee Acadians for food.

Lynx

The Canada Lynx (*Lynx lynx*) was recorded by eighteen of the twenty-one list-makers (Table 1). Though it was sometimes trapped for its fur (Stewart 1806†; MacGregor 1828†; Bagster 1861†), and for food (Holland 1765†; Patterson 1774†; Stewart 1806†), it was more generally viewed as a harmful predator of farm livestock. Johnstone (1822†) said that 'wild cats' sometimes preyed on cattle and sheep in the woods, while MacGregor (1828†), Bagster (1861†) and ([Lawson] 1877-1878†) noted that it specifically attacked sheep, killing several at a time without eating them. This, however, is contradicted by Stewart (1806†), who said that "very few of them have been known to attack sheep or lambs". Given this reputation, it is not surprising that in the 1820s a bounty (of five shillings) was instituted in an effort to exterminate the lynx, and from government records, Vass (1987) estimates that 357 bounties were collected between 1820 and 1861. Given the ease with which it could be killed with dogs, or caught in snares or traps (e.g., Stewart 1806†), combined with the loss of its habitat (Lawson 1851†), it is not surprising that an animal that MacGregor (1828†) had said was "rather numerous", and Bain noted had once been "not uncommon", was by 1890 "unknown" (Bain 1890†). As for its natural foods, Stewart (1806†) said that it lived on "hares and partridges"; Sutherland (1861†) mentions "small mammals, mice, birds, rabbits etc."; Rowan (1876†) noted its predation on hares; while Bain (1890†) said it ate "small quadrupeds and birds".

Seals

The presence of seals around the shores of the island was noted by many recorders throughout the French and British periods (Table 1), but without any other information being given than that they provided a source of meat and oil to the inhabitants, as well oil and skins for export (the export of some 860 seal skins was recorded in the island's customs records between 1802 and 1807). All of the recorders write as if only a single species were present except Stewart (1806†) who distinguished between two different "kinds" of seal, one of which, he said, was "very common" in all of the rivers and harbours of the island – this presumably was the Harbour Seal (*Phoca vitulina*). The other, he said, was "a larger kind brought on the coast annually in the month of April by the floating ice from the

northward; ... sometimes vast quantities come, other years little or none". This must be the Harp Seal (*Phoca groenlandica*), and Stewart goes on to describe the hunting of them from schooners. MacGregor (1828†) and Sutherland (1861†) combine together details applicable to each of these species, without realising they were describing two separate species, Sutherland adding that by his day seals were less common than formerly.

Walrus

It is odd that French period recorders make no reference to the presence of the Atlantic Walrus (*Odobenus rosmarus*) along the shores of the island, though La Ronde (1721†) noted the presence of the '*vache marine*', as he called it, in the Magdalen Islands, to which he said they were sending a ship from the island to participate in the summer hunt. The first record of the walrus directly on the island itself is thus that of the British surveyor Samuel Holland (1765†) (Table 1), who, however, stated that they "seldom or never come on shore but are now and then killed in the spring by the inhabitants in their canoes, when they happen to float too near the shore on pieces of ice". This, however, conflicts with some of the later British records, especially that of Stewart (1806†), who claimed that in the 1770s (he himself having arrived on the island in 1775) "sea cows" had been "found in great numbers on the north coast" (he especially mentions the area near North Cape), and he added that between 1770 and 1775 they were caught in considerable numbers there, the method being to drive the herds inland and then slaughter them using long spears. However, at the time that he was writing in 1806 he said that they "are now become scarce and seldom seen ashore". All of the later historical records for the presence of the walrus are thus retrospective (e.g., MacGregor 1828†; Hill 1839†; Sutherland 1861†), and all state that it was no longer observed around the island. The animal was killed especially for its oil, but there is also mention of the value of its hide for making ropes, harness and shoes (e.g., Curtis 1775††; Stewart 1806†; MacGregor 1828†; Hill 1839†; [Lawson] 1877-1878†), as well as of its tusks for ivory (e.g., Stewart 1806†; MacGregor 1828†).

Caribou

The first record of the presence of the Woodland Caribou (*Rangifer tarandus*) on the island is that of Nicholas Denys (1672††): he said that there were only a few on account of the Mi'kmaq being too fond of them for food to allow them to increase. Somewhat in conflict with this statement is that of La Ronde (1721†), who said that the Mi'kmaq did not find the Caribou easy to kill. The last French period record of their presence is that of Roma (1750†), who had left the island in 1746. The only record of their possible survival into the British period is that of Holland (1765†) who noted that there were "some, but very few Carriboux". If the species was still present in 1765, then it would seem to have become extinct shortly after, for ten years later, in 1775, Thomas Curtis recorded that none of the inhabitants whom he had met (and one of these had been resident since 1768) knew of any "deer" on the island (Curtis 1775††). I also say "if" for Holland's record because, as has often been demonstrated elsewhere, there is a tendency for people to believe that an extirpated animal is still present long after its disappearance, so that Holland, perhaps having been told by the Acadians of its past presence in small numbers, recorded it as still present. It is also significant that he did not include them as one of the animals that the refugee Acadians hunted for food, which they surely would have done, had it been present. Thereafter in the nineteenth century, the past presence of the Caribou was witnessed by the occasional finding of a "time-worn" antler in the woods (Lawson 1851†; Bagster 1861†; Rowan 1876†), though such antlers were also sometimes erroneously cited as evidence for the past occurrence of the Moose on the island (see below).

Squirrels and Chipmunk

That squirrels occur in only thirteen of the twenty-one lists (Table 1) is an indication not of their scarcity, but that, being of little value as either food or for their fur, they tended to be overlooked, except by those who set out to list all of the island's mammals. In fact during the French period the only recorder to note the presence of any of the squirrel species was La Ronde (1721†), who recorded the elusive flying squirrel, presumably because of its unusual mode of movement. In the early decades of British settlement, although several recorders noted the presence of different "kinds" of squirrel, they did not name them. Thus it was not until 1806 that the three species currently occurring are specifically recorded: the American Red Squirrel (*Tamiasciuris hudsonicus*), the Eastern Chipmunk (*Tamias striatus*), and the Northern flying squirrel (*Glaucomys sabrinus*) (Stewart 1806†), and thereafter, all three are listed by another five recorders (Table 1).

The red squirrel and the chipmunk were considered very plentiful (Stewart 1806†; Johnstone 1822†; Sutherland 1861†), but due to its nocturnal and elusive habits there was some uncertainty as to the abundance of the flying squirrel: Stewart (1806†) considered it not as common as the other two species, though Bain (1890†) said it was "not rare". Stewart (1806†) said that all three species, and particularly the chipmunk, increased "vastly" the year after a crop of beech mast, while Bain (1890†) said that the red squirrel was "plentiful in every wood where beech nuts were found". Bain (1890†) said that the chipmunk dug its burrow "under the roots of the great trees in a spruce wood", while the flying squirrel nested in hollow trees.

Muskrat

The Muskrat (*Ondatra zibethicus*) was listed by fifteen of the twenty-one list makers (Table 1), most of whom make no further comment about it. Though Bagster (1861†) said it was "by no means plentiful", Rowan (1876†) considered it to be "very plentiful", and Stewart (1806†), Sutherland (1861†), and Bain (1890†) said it was frequently seen about streams and ponds. There were opposing opinions about the value of its pelt: Bagster (1861†) said the fur was "useful and saleable", while Sutherland (1861†) said it was "thin and poor and little esteemed". Holland (1765†) included Muskrats as one of the animals that the refugee Acadians used for food, while Bain (1890†) noted that Muskrats, due to their habit of burrowing into the banks, were "troublesome about mill dams". As for its natural foods, Sutherland (1861†) and Bain (1890†) noted that it ate roots, shellfish and seeds.

"Plague Mouse"

During the French period, as well as in the first eighty years of British settlement, virtually the only species of mouse or vole that entered the records was the one responsible in occasional years for the destruction of the settlers' crops. This "plague mouse" damaged the crops several times during the French regime (e.g., Roma 1750†; Franquet 1751†; La Roque 1752††), while during the British period there were at least eight further outbreaks between 1770 and 1815 (Sobey 2006). However, by 1828 MacGregor noted that within the previous twenty years little injury had been done to the crops by "these mischievous animals".

Identifying the species responsible for the outbreaks has not been easy. Roma's (1750†) detailed description of the habits of the vole that caused the *fléau* [plague] of 1738, appears to better fit the Southern Red-backed Vole (*Clethrionomys gapperi*), rather than the Meadow Vole (*Microtus pennsylvanicus*), which has been more generally viewed as the culprit (e.g., MacQuarrie 1987): Roma's *mulot*, as he called it, was a woodland species (this, confirmed by all of the other French and British recorders, fits only the Southern Red-backed Vole); it made substantial underground food caches for the winter; and it was able to climb (although Roma said not as well as the *souris* (probably the Deer Mouse, *Peromyscus maniculatus*). These last two properties are characteristic of the Southern Red-backed Vole as described by Hamilton and Whitaker (1979) and Godin (1977), and appear not to apply to the Meadow Vole. However, I note that Banfield (1974) states that the Southern Red-backed Vole does *not* store up food for winter, whereas he says the Meadow Vole does. Unfortunately, the subsequent British period recorders do not supply any additional information that would enable us to settle the matter: what records there are, indicate the animal was a largish "mouse" with a short tail (e.g., Patterson 1770†; Shuttleworth 1793†). Even so, the further history of the outbreaks – the fact that they occurred only during the pioneer phase when new clearings were being opened up in the forest, and ceased as the forests were cleared – points also to the Southern Red-backed Vole.

Two alternative theories were proposed for the cause of the outbreaks by contemporary observers. Roma (1750†) and Patterson (1770†) considered that winters with heavy snow gave the voles protection from their predators, at the same time allowing them to feed from their stores under the snow; whereas Franquet (1751†), La Roque (1752††), Stewart (1806†) and Plessis (1812††) considered that the high production of beech mast in certain years was the cause. It is impossible retrospectively to determine which if either of these explanations is correct.

Other mice and voles

The first mention of a mouse other than the "plague mouse" is, Roma's (1750†) reference above to the *souris* [mouse] that he said was a better climber than the plague vole – this can only be the Deer Mouse. The next mention is over a century later: Sutherland (1861†) refers to two species of "field mice": the "burrowing field mouse", which appears from his description to be the Meadow Vole, and the "leaping field mouse", which, given its "long tail and strong hind legs", is likely to be the Meadow Jumping Mouse (*Zapus hudsonius*). Sutherland did not realize that there was another species of jumping mouse on the island, the Woodland Jumping Mouse (*Napaeozapus insignis*), first recorded by Cameron (1958).

The only other recorder to distinguish between the native species of mice and voles was Bain (1890†) who listed three native species: his "short-tailed Meadow Mouse" can only be the Meadow Vole since his brief description fits this species: "it lives on grain and grasses, and builds a nest of dry grass and makes long galleries under the snow in winter when it causes much destruction by barking young orchard trees". His two other species were "much less common": his "White-Footed Mouse" can only be the Deer Mouse, while his "Hamster Mouse" must be the Southern Red-backed Vole. He thus did not record either species of jumping mouse.

Snowshoe Hare

The Snowshoe Hare (*Lepus americanus*) is listed by all but two of the list-makers (Table 1), with many of the recorders noting that hares were abundant on the island. The only recorders to give any information on its habitat are Rowan (1876†), who said "their favourite resort is the second growth of young forest", and Bain (1890†), who noted they liked "dry ground in summer but frequent the swamps in winter". This was presumably related to the food they fed on in winter, which Bain (1890†) said was "young shoots of trees" – these were more specifically identified by Rowan (1876†) as "the tender twigs of maple, moosewood, birch, willow, alder etc.". Both recorders said

that in summer they fed on "grass". Rowan said that on the island their natural enemies were the Lynx, Marten, Weasel and Fox, as well as birds of prey, and man. Almost all of the recorders refer to the Snowshoe Hare in the context of a game animal, and in the early years of settlement it seems to have been an important supplementary food source for the human population (e.g., Curtis 1775††; Chappell 1775-1818††). Hares continued to be eaten throughout the nineteenth century and were considered a delicacy by many. However, Johnstone (1822†) and Sutherland (1861†) considered their fur to be of little value.

Absences in the records

Moles

Although Johnstone (1822†) stated categorically that "there is not a mole on the island", two later writers of school textbooks for the island (Sutherland 1861†; Bain 1890†), included it in their lists of the island's mammals, both using similar phrasing: "it burrows in the ground and lives on worms". Despite their assertions, there is no evidence that a species of mole has ever occurred on Prince Edward Island, and neither Cameron (1958) nor ACCDC (2008*) have included it in their lists of the native mammals.

Fisher

The Fisher (*Martes pennanti*), which currently occurs in Nova Scotia and New Brunswick, is entirely absent from the historical records for the island. Thus the inclusion of Prince Edward Island in the animal's historical range by Cameron (1958), Peterson (1966), Banfield (1974) and ACCDC (2008*) is not supported by the early records.

Moose

There is no historical evidence that the Moose (*Alces alces*) ever occurred on Prince Edward Island, at least during the settlement period, and in fact there is strong evidence to the contrary: during the French period Denys (1672††) and La Ronde (1721†) had made a point of recording that the Moose was absent from the island, as did Sutherland (1861†) during the nineteenth century. The five British period records of its occurrence are late and retrospective (Table 1), and are all based on the anecdotal finding of "moose horns" in the woods – it was this evidence that led Cameron (1958) and Banfield (1974) to list the Moose as once occurring on the island. These "horns", however, are far more likely to have belonged to the Caribou, for which there is irrefutable evidence of its past occurrence.

Beaver

The only historical record for the occurrence of the American Beaver (*Castor canadensis*) on Prince Edward Island (that is, prior to its deliberate introduction in the twentieth century) is that of Bain (1890†) who said that it was "once common here and the remains of its dams are still to be seen in many parts of the country". This is a curious statement since fourteen years earlier Rowan (1876†) had said that he had not seen or heard of any "beaver works" on the island, and so he was "inclined to think" they had "never lived on the island", as "their traces endure long after they have become extinct". So also had Sutherland (1861†) included it in a list of the mammals found on the mainland that did *not* occur on the island. The validity of Rowan's and Sutherland's observations is strongly supported by the fact that its absence from the island had been noted at the beginning of French settlement by La Ronde (1721†), as well as by the fact that none of the other list-makers had included the beaver in their lists of the island's mammals, including Stewart (1806†), Johnstone (1822†) and MacGregor (1828†) who had made fairly comprehensive lists. Given the commercial importance of its fur and its relatively large size, it was a mammal that, had it been present, would not have been overlooked. Apart from Bain's comment, the only other mentions of the beaver that I have come across in the historical records are its inclusion in a list of the retail prices of pelts, printed in a pamphlet for immigrants to the island (Anonymous 1808††), and the presence of beaver pelts among a consignment of animal skins shipped to Halifax in 1802 (Sobey 2006). Since pelts were easily transportable from the mainland, where the species did occur, neither record indicates its presence on the island. It should be noted that the beaver's absence from the island from 1720 onward does not exclude the possibility that it had been trapped-out prior to the eighteenth century. The evidence in support of such a view, however, is limited to the finding of a beaver incisor tooth in an archaeological dig at a prehistoric aboriginal site (probably Mi'kmaq) near East Point that was occupied from about 800 to 1000 AD (Keenlyside 1983) (though such a small item could have been easily carried from the mainland), and the unreferenced statement of Cameron (1958) that beaver tooth-marks had been found on sticks from island peat-bogs.

Other absences

Sutherland (1861†) noted the absence of the Raccoon (*Procyon lotor*) from the island, as well as the American Porcupine (*Erethizon dorsatum*) (as had La Ronde IN 1721†), both of which he noted as occurring in Nova Scotia and New Brunswick; while Rowan (1876†) noted the absence of the "Virginian deer" (i.e., the White-tailed Deer, *Odocoileus virginianus*). The validity of these statements is supported by the fact that none of these animals was noted as present by any other of the historical recorders.

Discussion

The island's native mammalian fauna

Thirteen of the island's native terrestrial mammals were recorded by French period observers (Table 1),

with British period recorders taking the total to twenty. On the basis of the current ACCDC (2008*) mammal list for the island, we may surmise that the number of terrestrial species at the time of settlement might have been 28. This includes my deletion of the beaver and Fisher from the ACCDC list, and ignores the post-settlement arrivals of the Brown Rat (*Rattus norvegicus*), House Mouse (*Mus domesticus*), Striped Skunk (*Mephitis mephitis*), Racoon and Coyote (*Canis latrans*), the latter three in the twentieth century. The eight omissions from the historical record are all small mammals: the island's five species of shrew (assuming those currently in the ACCDC list were also present in the eighteenth century) were treated by the early recorders as one species, as were the four species of bat; while one of the five species of native mice and voles went unrecorded (the Woodland Jumping Mouse *Napaeozapus insignis*, first recorded by Cameron 1958). As for the marine fauna, three species are distinguished in the historical records: the Walrus, and seemingly, the Harbour Seal and Harp Seal. Thus the two other seal species listed by ACCDC (2008*) as currently occurring in the Gulf of St. Lawrence (the Grey Seal, *Halichoerus grypus* and Hooded Seal, *Cystophora cristata*) are not discernable in the historical records for the island.

Despite the absence of three key boreal elements from the records (the Moose, porcupine and beaver), the terrestrial fauna recorded at the beginning of European settlement is a boreal fauna, signalled in the records by the presence of the Snowshoe Hare, Red Squirrel, Northern Flying Squirrel, Southern Red-backed Vole, American Marten, Short-tailed Weasel, Canada Lynx, and Woodland Caribou. All of the other mammals recorded (e.g., the American Black Bear, Grey Wolf, Red Fox, American Otter, Mink and Muskrat) are also quite at home in the boreal forest zone, though occurring widely in more southerly areas as well (e.g., Banfield 1974; Hall 1981). Concomitantly, there is a total absence of mammals characteristic of the more southern deciduous forest zone (e.g., the Striped Skunk, Racoon, Eastern Grey Squirrel, *Sciurus carolinensis*, and White-tailed Deer); and if Denys (1672††) is to be relied upon, none of these were present in the rest of Acadia (including eastern Maine) in the seventeenth century – though in the last two centuries such southern species have reached the adjacent mainland and some have even been introduced onto the island (i.e., Striped Skunk and Racoon).

The presence of the Woodland Caribou, along with its predator, the Grey Wolf, is one of the more interesting pieces of information to emerge from the records of the period, and is a corrective to Lohr and Ballard's (1996) statement that wolves never occurred on Prince Edward Island. As I have noted, it seems that neither species was abundant, and La Ronde (1721†) said that the reason the Mi'kmaq did not spend the winter on the island was that they found the Caribou difficult to kill (he actually called them *cerfs* or "deer"), the implication being that there was little else for them to eat in winter – which would indeed have been so, given the absence of the beaver and the Moose, two of their traditional winter food animals (e.g., Denys 1672††). We thus have here a clear instance of the natural fauna (both presences and absences) having important effects on the aboriginal population.

The importance of the beech forests

The historical evidence indicates that American Beech was a very important tree in the upland hardwood forests of the island, with large areas of the land surface being covered by beech forest (Sobey 2006). Beech produces a nut (traditionally called mast), which provides an important food for many different animals (e.g., Tubbs and Houston 1990). In the historical records for the island we are told, as we have seen, that the Red and Flying squirrels, the chipmunk and the "plague mouse" fed on the mast, as also, we may presume, did all of the other woodland mice and voles. Evidence from elsewhere (e.g., Vass 1987; Telfer 2004) indicates that the American Black Bear was also likely to have done so.

The North American Beech has long been known to be irregular in its seed production, with "mast years" occurring every two to eight years (Tubbs and Houston 1990). That the beech forests on the island also exhibited such mast years is recorded by Franquet (1751†), La Roque (1752††), Stewart (1806†), Plessis (1812††) and Bain (1868-1884††). As we have seen, such mast years were considered by some to be the cause of the vole irruptions, while Stewart (1806†) said that the three squirrel species (and of these, especially the chipmunk) also showed a "great increase" in numbers "after an abundant crop of beech mast". And though they did not enter the written record, we may presume that all of the other feeders on beech mast would also have been affected. As well, the distribution of beech forests on the island might have affected the spatial distribution of the mast-feeders, and this may not have been only in mast years. However, the only evidence that we have for this is Bain's (1890†) comment that the red squirrel was "so plentiful in every wood where beech nuts are found".

Given this recorded increase in the mast-eaters, we might expect that the island's predator populations might have concentrated on them when they were abundant – Roma (1750†) had certainly noted that the fox and the marten fed on the voles during a plague year. We have a hint that this abundance of prey may have also led to a increase in the *numbers* of the predator species, in Franquet's (1751†) statement that foxes, martens, mink and lynx were more abundant in some years than in others, as well as Stewart's (1806†) that the marten was in "great abundance" in some years. However, confounding factors here are the so-called "long" or "nine to ten year cycle" in the numbers of the Snowshoe Hare and its predators (especially the

lynx) that has long been recorded throughout its North American range and the "short" cycle (of two to three years) that commonly occurs among rodents and their predators in northern environments (e.g., Finerty 1980).

We can only speculate on the effect that the great decline in the area of beech forest has had on the ability of the forests to sustain the food-webs that they did before European settlement. Prior to forest clearance, beech was a predominant tree, Stewart (1806†), for example, saying that "one-half of the island is covered with it, in some districts it forms nine-tenths of the forest". By 1991, however, beech contributed only 4.1% of the woody biomass in the remaining upland hardwood forest (Sobey and Glen 2002), and far less when all of the forest-types are considered. Thus those mammals still occurring on the island that were once substantial mast-eaters (the chipmunk, squirrels, voles and mice) have had to turn to other types of food.

The utilization of the mammalian fauna for food and fur

All of the French period mentions of the Caribou refer to it in the context of game, either for the aboriginal Mi'kmaq (Denys 1672††; La Ronde 1721†) or the new French settlers (Gotteville de Belile 1720††; Roma 1750†). Then, after the Caribou's extirpation in the mid-eighteenth century, the animal most mentioned as a source of food is the Snowshoe Hare. As well, other animals that most people nowadays would not consider edible are also recorded as being eaten by the European population, notably the bear and the lynx, while Holland (1765†) reported that the refugee Acadians were eating even martens, otters and Muskrats. The island's seals also served as food for the Acadian population in the early years (La Ronde 1721†; Roma 1750†; Patterson 1770†), as did oil from the walrus (Stewart 1806†). However, once settlement was established, the native fauna seems to have become unimportant as a food source, though the hare continued to be mentioned as a game animal throughout the nineteenth century.

Would the hunting of any of these animals for food have had any effect on their numbers? It is probably not a coincidence that the Caribou disappeared from the island within a few decades of the establishment of the first permanent settlement in 1720: the small numbers reported to occur (e.g., Denys 1672††; Holland 1765†) would have been vulnerable to even low levels of hunting. Also, the hunting of the walrus for its oil may have contributed to its disappearance from island waters. By contrast, the Snowshoe Hare continues to thrive on the island, and any hunting, even in the unregulated early days, seems to have had little effect.

As for those animals that served as food only under extreme conditions, it is clear that hunting was another pressure that contributed to their extirpation, namely, their being hunted for their furs. However, though many recorders, as we have seen, stress the value of the furs of the otter, marten, mink, Red Fox, and black bear, and to a less extent the lynx and the Short-tailed Weasel, concrete data on any fur trade that developed on the island is sparse in the historical record. For the French period, the only specific references are Roma's (1750†) comment that "*la chasse aux martres* [i.e., marten-hunting] should be reserved to the Mi'kmaq to enable them to "procure their needs", and the entry in the 1757 journal of an officer aboard a French warship at Louisbourg that "the Indians of Île Saint-Jean usually come to Louisbourg in August and September to sell their animal pelts which brings them a very good profit" (Sobey 2006).

In the British period, the only recorder to give the fur trade more than a passing mention is Samuel Hill (1839†), who wrote that "there was once a considerable export of furs from the island". The island's customs records contain evidence of two such early fur shipments: the *Betsy*, bound for Halifax in June 1802, had amongst its cargo "4 Trunks of furs, containing Rabbit, Fox, Martin, & Beaver skins, a few seal skins & 30 Dozen loose rabbit skins"; while in May 1819 the *Nelly*, also bound for Halifax, had 1200 "rabbit" skins, 162 martin, 14 otter, 1 lynx, and 1 bear. (The presence of beaver skins in the 1802 shipment indicates that at least some of the furs had come from the mainland.) Also, the inventory of the estate of one John Rennie in 1791 recorded that at his death he was in possession of "six dozen dressed marten skins" (Nicholson 2004).

When Hill goes on to comment on the fur trade of the 1830s he highlights the role of the Mi'kmaq: "foxes are chiefly shot or trapped by the Indians, and their skins exported to England by the resident merchants", and other writers also refer to the skills of the Mi'kmaq in the trapping of the native fauna (Johnstone 1822†; MacGregor 1828†). And there is also an 1830s record of the export of furs in the customs records: the *Catherine Jane* bound for Liverpool in May 1834 carried 493 fox pelts (of which 19 were cross and 4 silver), 440 marten, 60 "rabbit", 40 lynx, 31 otter, 29 mink, 2 Raccoon, and 1 Muskrat. As was so for the beaver above, the presence of the two Raccoon pelts indicates that some of the skins must have come from the mainland, since the Raccoon is otherwise absent from the historical records for the island.

Extirpations among the fauna

Four of the fur-bearers were eliminated from the island: the marten, otter, lynx and black bear, as were also the caribou and the wolf – as well as the walrus from the waters around the island. We may question whether all of these extirpations were inevitable. Granted that the large-scale destruction of forest to make way for farmland would have resulted in a considerable loss of habitat and a resulting decline in the total numbers of all of the terrestrial mammals; even

so, with the exception of the caribou and the wolf, which are both likely to have required a greater area of forested habitat than what remained, the other four land mammals should have been able to survive in the remaining areas of forest and other habitat. In the British Isles the Pine Marten (*Martes martes*) and European Otters (*Lutra lutra*) have been able to survive in landscapes greatly altered by human activity, and in association with as high or even higher human population densities than on Prince Edward Island (e.g., Corbett and Southern 1977; Jefferies 1989). It thus seems that had there not been the uncontrolled trapping of the marten – an animal notoriously easy to trap (e.g., Banfield 1974; Hamilton and Whitaker 1979) – it very likely could have survived. As for the Otter, though habitat loss may have played a role, the rivers and bays that were its habitat being directly adjacent to the areas first selected for settlement, unregulated trapping appears also to have been the main reason for its extirpation. In fact, it was not until 1879 that the island's House of Assembly passed its first act "for the protection of Game and Fur-bearing Animals", which, among other measures, restricted the season for taking Muskrat, marten, and otter to between 1 November and 1 May (Glen1995).

As for the lynx and the black bear, had there not been active hostility towards them, including the institution of bounties, it is possible that they could also have survived. According to Anonymous (2003*), "as long as they are not disturbed", lynx are "remarkably tolerant of human settlement" (see also Poole (2003)), while the last bear on the island was shot as late as the 1920s – some forty years after the peak of human population density. As for the Walrus, though the island's first British governor was aware of the need for controls on the "sea cow fishery" and even had his council pass an ordinance in 1770 to regulate it, he was aware that the hunt, being largely carried out by "vessels from New England", was beyond the control of his infant government (Patterson 1774†).

We may thus conclude that though the *activities* of the settler population led to the seven extirpations, an important factor contributing to four of them was the *attitude* of the settlers: a positive hostility to the lynx and the bear (understandable in the light of their predation on livestock), and an indifference to the survival of the otter and the marten so that the necessary protections were not instituted until it was too late.

Acknowledgments

I thank Professor Gerry McKenna, then Dean of Science at the University of Ulster, for enabling me to take six months sabbatical in 1996 so that I could initiate the study, and Harry Baglole of the Institute of Island Studies at the University of Prince Edward Island for supporting a research associateship at the university. I also thank the staff responsible for the P.E.I. Collection at the Library of the University of P.E.I. and those at the P.E.I. Public Archives and Record Office for assisting me with locating and copying documents, as well as the P.E.I. Department of Environment, Energy and Forestry, and in particular William Glen and Kate MacQuarrie, for supporting the research. I also thank William Glen for directing me to some of the fur data in the customs records.

Social and Play Behavior in a Wild Eastern Coyote, *Canis latrans*, Pack

JONATHAN G. WAY[1,2]

[1]Science Department, Barnstable High School, 744 West Main Street, Hyannis Massachusetts 02601 U.S.A. e-mail: jon@easterncoyoteresearch.com
[2]Mailing address: Eastern Coyote Research, 89 Ebenezer Rd, Osterville Massachusetts 02655 U.S.A.

Way, Jonathan G. 2007. Social and play behavior in a wild eastern Coyote, *Canis latrans*, pack. Canadian Field-Naturalist 121(4): 397-401.

I had close and consistent observations of a wild eastern Coyote pack (*Canis latrans*) from January 2000 to August 2007. During this time, I obtained 3156 radio-locations on a specific radio-collared breeding male ("Sill") and observed him and/or members of his pack on 375 occasions. The average group size = 3.0 ± 2.3 (SD) Coyotes with 1.9 ± 1.2 (SD) being adults and 1.1 ± 1.9 being pups. Maximal group size involved 12 Coyotes (9 pups, 3 adults). During these observations, Coyotes most often behaved in a friendly manner toward each other as indicated by 80 of my observations involving play between pups, and 15 involving play among adult Coyotes. On the evening of 6 July 2007 I observed the breeding male (>8 yr old), his mate (>5 yr old), one of their full-sized probable yearlings, and five pups playing intensely for 33 minutes. This paper details social and play behavior from this pack, especially from the 6 July 2007 observation.

Key Words: *Canis latrans*, eastern Coyote, amiable/affiliative interactions, play behavior, Massachusetts.

Although not exclusively a mammalian trait, play is an important social activity for mammals, and especially for carnivores (Bekoff 1972a, b, 1989; Ewer 1973; Rennicke 2007). It is characterized by (1) friendly, non-aggressive (or amiable) intentions; (2) more energy than is strictly necessary; and (3) a typical air of eagerness, excitement, and enjoyment during interactions (Ewer 1973; Bekoff 1974a, b, 1989). Although play is not unknown in adults, it is displayed more commonly in young animals (Bekoff 1978), and provides the means of doing all the things the central nervous system is prepared for without any of the risks inherent in a "real" (e.g., hunting, fighting) situation (Ewer 1973). Hypotheses about the function of play in canids have been reviewed by Bekoff (1974a) and Packard (2003) and include (1) the ability to learn counter-tactics during play that may provide a basis for learning complex social relationships later in life; (2) physical exercise related to aerobic conditioning; (3) development of muscular routines; (4) practice of instincts useful for hunting later in life; (5) a demonstration that "animals that play together, tend to stay together"; i.e., social cohesion; and (6) an indication that it may simply be fun and a pleasurable experience.

In the vast majority of studies on Coyotes (*Canis latrans*) (and on carnivores in general), play behavior has occurred with juveniles in captivity where researchers can easily observe their study subjects and quantify behavioral observations in a controlled setting (Bekoff 1972a, 1974b, 1978, 1989; Way et al. 2006). Packard (2003) noted that our understanding of Wolf (*Canis lupus*) social behavior will advance more rapidly when we integrate the information from both captive and field populations, as long as we take great care to recognize the limitations of each perspective and to understand the whole as the sum of the parts. However, few studies have examined the play of Coyotes and Wolves in the wild (Ortega 1988; Mech 1997; Packard 2003). Of these studies, all detailed play behavior was observed only in pups.

For instance, Mech (1997: 75) watched wild Wolf pups in the Arctic play "for about 45 minutes as the pups scrambled back and forth across the snowfield, chasing one another, tackling, sliding, rolling, skidding, and carrying on to a degree I have never seen nor heard of before for any species." Observations of pups playing is a common theme in studies on play behavior in canids, and despite some authors claiming that adult canids play (e.g., Bekoff 1989; Lehner 1978; Packard 2003), there is scant evidence of this in the wild, possibly due to their need for conservation of energy, certainly in harsh climates. In this paper I describe a social, amiable, wild Coyote pack, including observations of the older adults in the pack playing.

Methods

Research was conducted in an urbanized area (town of Barnstable on Cape Cod) in eastern Massachusetts (see Way et al. 2001, 2002a, 2004). Average human density on the study site was 290 people/km^2 and road density was 4.66 km of roadway per km^2 (Cape Cod Commission 1998*). Observations began on 18 January 2000 when the Coyote "Sill" (ID # 0003), a 16.8 kg 9-month old male Coyote was captured in a box trap (model 610B, 152.4 cm × 50.8 cm × 66.0 cm, Tomahawk Live Trap Co., Tomahawk, Wisconsin, USA: Way et al. 2002b) in Cotuit (within the town of Barnstable), Massachusetts, and radio-collared as part of an ongoing study of eastern Coyote ecology on Cape Cod (Way et al. 2002a, 2004). Sill was tracked on his natal range (his father, "Kett," ID # 9805, was also radio-collared) until January 2001 when he dispersed

and settled into a vacant territory to the immediate east of his natal range in February/March 2001 (see Way 2007* for more details). He was the dominant male of that new pack (Newtown/Bog Pack) in Marstons Mills (within the town of Barnstable) from 2002 to 2007, when the study ended.

Tracking protocols were fully described by Way et al. (2002a, 2004). Portable receivers (Custom Electronics, Urbana, Illinois, USA) and hand-held 3-element Yagi antennas were used to radio-track Coyotes both on foot and from a vehicle. Animals were typically homed in on using the loudest-signal method of radio-tracking (Springer 1979). I approached radio-collared Coyotes as closely as possible without disturbing them. I used binoculars, 15-45 × spotting scopes (Bushnell, Overland Park, Kansas, USA), and video-cameras when observing Coyotes at den and rendezvous sites (Way et al. 2001, 2003), and spotlighting and headlights when following Coyotes at night with a vehicle (Way et al. 2002a, 2004).

Collared Coyotes were often seen with untagged companion(s), especially when at rendezvous sites (Way 2003). A detailed description (e.g., size, coloration, distinguishing markings, and behavior) of the uncollared animals was made during every direct observation. In this manner, the unmarked Coyotes were identified based on appearance, as described by Way et al. (2002a) and Way (2004). Overall, I identified as many Coyotes as possible from Sill's pack, as well as from other groups within the study area. I classified Coyotes as adults or pups/juveniles. Adults were classified as all full-sized Coyotes and often included yearlings that remained on their natal territory. Pups were born in April (Way et al. 2001) and were classified as such until October, when they approached full body size and became indistinguishable from adults when observed in the field. Due to the logistic difficulties of keeping track of large groups (≥5) of Coyotes observed at the same time (especially when they temporarily separated and were all visible at the same time but only one observer was there to monitor them in separate locations), it was necessary to began with this simple coding scheme (pups or adults).

Most of the lengthy sightings were made at two sets of cranberry bog complexes (2-3 bogs at each location; complexes were 1 km apart) where distant (~400 m) viewing was possible (Way 2003, 2007*). Sill's pack began using these bogs in summer 2003 following the death of an old female Coyote ("Mole" #0110) in the pack to their immediate northeast (Way and Strauss 2004; Way 2007*). To avoid autocorrelation (see Way et al. 2004), sightings were separated by > 4 h from each other. Typically this meant that Coyotes were observed during dawn and/or dusk on a given day with occasional daytime observations (n ~25).

Play was defined as the behavior that was performed during social interactions in which there was a decrease in social distance between the interactants, and no evidence of social investigation or of agonistic or passive-submissive behaviors on the part of the members playing, although these actions may occur as derived acts during play (e.g., passive submission during a play bout – Bekoff 1972a, 1974a; Way et al. 2006). Bekoff (1974a) classified play as (1) incorporating various contexts into unpredictable temporal sequences; (2) preceded by a metacommunicative signal (e.g., play initiation); (3) repeated and performed actions in an exaggerated manner; and (4) appearance of being pleasurable to the participants, e.g. a play face (wide open jaws and eyes) is apparent. Included in play were numerous role reversals where more dominant Coyotes allowed lower ranked Coyotes to pin them to the ground; this was never documented during agonistic displays (Way et al. 2006).

I used continuous animal sampling (Martin and Bateson 1986) to record Coyote activity and recorded the behavior (via scan sampling) of as many Coyotes concurrently as I could during my observations. I recorded data into a field notebook and video-camera for later analysis.

Results

I obtained 3156 radio-locations on Sill and observed him and/or members of his pack 375 times (>4 hours apart) from January 2000 to August 2007. The average Coyote group size during the 375 sightings was 3.0 ± 2.3 (SD) Coyotes with 1.9 ± 1.2 being adults and 1.1 ± 1.9 being pups. Maximal group size observed during an observation involved 12 Coyotes (9 pups, 3 adults), while two sightings involved 10 Coyotes (3 adults and 7 pups) and eight sightings involved 9 Coyotes (ranging from 2-7 adults and 2-7 pups). This pack was typical of other eastern Coyote social groups (see Way et al. 2002a, 2003) in that Sill had a mate ("Mange-back", positively identified from 2004/2005 to 2007, having a distinct missing patch of fur on the top of her neck and a large softball-sized bleached-like looking mark on her left rib which looked like a distinct blonde splotch on an otherwise brown body) and those two comprised the breeding pair while the remaining adults appeared to be yearlings, or pack associates, most likely their offspring from the previous year. On any given year there were 3 to 5 adults (including associates/yearlings) and four or more pups. Sill's group was especially visible for the four and a half years from 2003 to 2007 when they adjusted their territory to include two complexes of several cranberry bogs each, formerly used by a pack to their northeast. Although many of the sightings were temporary (e.g., one or two Coyotes observed for 1-2 sec while crossing a road at night), 160 (42.7%) observations occurred at rendezvous sites averaging 44.5 ± 31.4 (SD) min (maximum bout = 142 min) in duration. These rendezvous site observations produced all of the observations of play detailed below.

Coyote pups often played with each other during observation bouts (n = 80) at the rendezvous sites, which consisted of chasing, wrestling, and self-play (Way et al. 2006). It was very apparent when they were playing because role reversals often occurred where small pups pinned larger, more dominant ones (Rennicke 2007). Also, chasing often involved different combinations of chaser(s) and chasee(s) where close observations indicated open (sometimes panting), relaxed mouths. In all observations, colleagues, some of my students, or the general public (I usually observed from a main road and people frequently stopped to observe with me) agreed with my assessment of play rather than another behavior (e.g., agonistic). On 15 occasions, I observed adult Coyotes play with one another. These were frequently games such as group-chases or wrestling matches where pups also became involved. The only negative interactions that I observed between adults was when one probable yearling pinned another (n = 9 observations). I did not observe any aggressive acts directed toward Sill or his mate "Mange-back" but on four occasions Mange-back aggressively pinned another (probable female) Coyote into a passive submission posture. Based on subsequent observations, these Coyotes were likely her yearling daughters.

Sill was a very diligent father and often returned to the rendezvous sites throughout the year. Many of my observations consisted of him and 1-2 others (usually adults) returning from patrolling their territory at night to joining other Coyotes waiting at these sites (i.e., full-sized pups). During the summers of 2005 to 2007, when I positively identified Mange-back as his mate, I more often saw Sill (80% of sightings) at the rendezvous sites (July-October) with the pups than Mange-back (~60% of sightings involved her). All Coyotes acted submissive to Sill except for Mange-back, who rarely interacted with him, likely because of their familiarity with one another. Yearlings (n = 20 sightings) and pups (n = 75) often greeted Sill in an active submission posture which involved repeated licking of his mouth with exaggerated tail wagging by the intended recipient (Way et al. 2006). Sill frequently regurgitated (n = 10-12 observations) to pups when solicited, especially when returning to the rendezvous sites from surrounding areas. In fact, the only negative (agonistic) interactions I observed was when Sill growled at persistent pups (n = 10-12 observations) who repeatedly tried to lick his mouth to try stimulating him to regurgitate. All of the factors detailed herein indicated that Sill was the breeding male of a large, very successful, and amiable eastern Coyote pack.

The evening of 6 July 2007 produced the most memorable observations of amiable and play behavior from this pack. For 33 minutes I observed three adults (out of four in the pack at the time) and five pups from the pack (one of which was later hit and killed by a car on 20 July), including Sill (8 years, 3 months old at the time), Mange-back (likely >5 years old), and a yearling male named "White-band" (for a white band running laterally on his tail just posterior to the base) that was the same size as Sill. They were at the northern-most area of the two rendezvous sites (north of the site from Way 2003). At 20:15, I arrived at the rendezvous site and immediately saw eight Coyotes about 250 m NW of my location on Bog Road in Marstons Mills. They were at the junction between the northwest part of the east bog and northeast part of the middle bog (three bogs comprised this area west of Bog Road) in an open sand flat (about 25 × 20 m) dubbed "Olivia's" (O) flats for a homeowner's walking trail that leads southeast to this location ~75 m from her house.

When I arrived, I immediately set up my tripod and spotting scope as the pups were particulary active and running back and forth playing, both play chasing and play wrestling (see Way et al. 2006). At 20:20, Sill walked west about 50-75 m and bedded in sit1 alert position (Way et al. 2006) on a small (1.5 m high) mound of sand, next to a small shed/pumphouse just north of the northcentral part of the central bog. He sat alert and watched the other seven Coyotes from a distance until 20:25, when Mange-back led the five pups to the sand mound where Sill was sitting. To get the pups there, she turned around and faced the pups and took a few steps toward them until they followed her. I was too far away to hear if she called them over or if they just followed her, but she did that two or three times before completing the short trip. White-band followed the group west to the sand mound.

After trotting to that location (~15-20 sec.) the pups immediately re-engaged in intense bouts of play chasing and play wrestling. Sill greeted a couple of the pups by licking them but mostly stood up when the group arrived and then proceeded to watch them. At ca. 20:30, Mange-back, which was watching the pups play for ca. 2-3 min, got into the games by pinning a couple of pups. She had a noticeably relaxed play face (Bekoff 1974a, 1974b; Lehner 1978) and jumped back and forth as a couple of pups chased after her. Sill and White-band watched the actions right on the mound and despite pups bumping into Sill, he maintained his vigilance by surveying the area for danger.

At 20:32 Sill became active. He gathered a couple of pups, then trotted east back to the O flats. Mange-back and White-band followed him. Immediately upon approaching the O flats, he did a play bow (Way et al. 2006) to initiate play from the two pups. The pups immediately responded by chasing him and he, like Mange-back on the sand mound, stayed contained within a localized area (the O flats) instead of running from the pups as he sometimes did to get away from them. In other words, it was obvious during this particular observation that he was purposefully playing with the pups.

For the next 10 min, Sill engaged in vigorous bouts of play chasing with groups of two to three pups at a time, after the other three pups returned to the area as well. The action occurred quickly, but I believe that

he played with all five pups by the end of the session as pups were constantly changing directions and conspecifics with which they interacted. I could easily see Sill's tail wagging and his mouth open and relaxed, similar to the pups when they played. By 20:40 it was nearly dark and becoming difficult for me to see, but at this point all of the Coyotes gradually diminished their activity except for White-band which did not engage in play on that particular night. He often baby-sat the pups during summer 2007 and may have felt the need to watch them instead (although I did observe him ≥ 4 times playing with the pups that summer).

At 20:42 Sill trotted at a steady pace southwest on a canal separating the east and central bog, leaving the pups at the O flats area. When he got to the south edge of the canal (~200 m) he approached the north edge of a private property that has a ca. 40 kg Labrador/Golden retriever Domestic Dog mix ("Kota") with which he commonly interacted (by growling and barking at each other, usually from opposite sides of the bogs) south of the southeastern part of the central bog. When Sill approached the edge of Kota's yard (Kota was not outside) he sniffed then raised-leg urinated on a bush followed by a ground-scratch, common behavior I observed from him when marking his territory. He then proceeded to trot west at the south part of the bog complex, displaying a noticeably different and more serious disposition than when he was playing with the pups. He kept his tail at a 45° angle and was very alert and tense on his route west. At 20:44, Mange-back and White-band left the pups and trotted through the central bog in the general (southwest) direction of Sill, but taking a more northerly counterclockwise route, likely to avoid Kota. All three adults gradually made their way to the south part of the west bog west of Bog Road and eventually became too difficult to see at 20:48. Sill's signal (at 20:58) indicated that he continued south, crossed a secondary road (River Road), and went to the south of the two cranberry bog rendezvous sites (detailed in Way 2003). Meanwhile, the pups remained around the O flats, eventually heading northeast into the wooded patch where they commonly rested and hid. I departed the area at 20:50 at dark.

Discussion

This Coyote social group behaved in a remarkably friendly manner toward one another and similar to what has been described for Wolves, other than that they preyed on small animals (rodents, rabbits), trash and other human food, and domestic cats (J. Way, unpublished data) rather than large ungulates (see Mech et al. 1998; Mech and Boitani 2003). In fact, it was obvious to me that the Coyotes, including adults, were having fun when they played, as demonstrated by such characteristics as a play face, tail-wagging, and/or engaging in affiliative activities which have been purported as nothing but play (Bekoff 1972a, 1974b; Packard 2003; Way et al. 2006). Such canid play characteristics are obvious and recognizable to dog owners when their pet dogs are playing.

Bekoff (1999) claimed that social play may provide more promising evidence of animal minds than research in many other areas, for it may yield clues about the ability of animals to understand one another's intentions. While watching Sill, it was difficult for the pups (and for me as an observer) to misinterpret Sill's intentions from play bowing to initiate play, to a more serious (tail at 45° angle) posture when he departed for his nightly travels (when none of the pups attempted to follow him). It is highly likely that the success of this social unit was predicated on the stability of the pack members, mainly Sill and Mange-back. By being mature older adults and extremely familiar with the area (see Way 2007*), these two Coyotes were never observed getting challenged by their younger, less experienced offspring.

This particular area (i.e., the open cranberry bog complexes) has produced some memorable Coyote sightings, including observations of Coyote pups for 11 years in a row (1997-2007: see Way 2003, 2007*). However, I do not believe this group to be the exception to the norm. Other packs in my study area, although less visible on the average, have similar social units and were occasionally observed in comparable amiable scenarios where adults were seen playing with one another (e.g., see Way 2001* and Way 2007*). Many of these observations of friendliness/play included older adults (usually radio-collared) which, like Sill, probably provided stability and experience to their pack. The eastern Coyote's family-oriented nature cannot be understated. In one instance, I have even observed two adults in a Coyote pack raising pups when an older, breeding female was killed when the pups were young (Way 2004).

Due to its success, the Coyote is typically maligned by the public and is often treated as vermin or pests by state wildlife agencies and/or animal control/pest agencies (Way 2007*). However, Coyotes are highly social, family-oriented, caring animals (Camenzind 1978; Bekoff and Wells 1980; Gese et al. 1996; Crabtree and Sheldon 1999;) that probably even enjoy life and each other (Way 2007*; this study). Once thought to be too subjective, there is a growing body of literature that supports this statement (e.g., see Bekoff 2002, 2007), and data from this paper regarding this one pack studied over eight years (2000 to 2007), provides irrefutable corroboration of Coyote sociality, including amiable/affiliative behaviors such as play.

Acknowledgments

I thank my family (especially my wife Tara), Marie Thomas, Eric Strauss and Boston College, and Barnstable High School for helping me with various aspects of my research. Two anonymous reviewers provided helpful comments.

Fortin, Christian, Martin Ouellet, Isabelle Cartier, Daniel Banville, and Claude B. Renaud. 2007. Biologie et situation de la Lamproie du Nord, *Ichthyomyzon fossor*, au Québec. Canadian Field-Naturalist 121(4) : 402-411.

La Lamproie du Nord est une espèce propre à l'Amérique du Nord et elle ne se rencontre, au Québec, que dans l'extrême sud de la province. Cette lamproie a été observée dans le fleuve Saint-Laurent ainsi que dans 11 de ses tributaires. Elle aurait disparu de la rivière Yamaska où elle avait été recensée entre 1946 et 1959. Poisson non parasite, sa taille au stade adulte ne dépasse habituellement pas 160 mm. Les larves, appelées ammocètes, et les adultes ne se retrouvent qu'en eau douce. Les cours d'eau utilisés sont généralement des ruisseaux et des rivières à fond graveleux ou sablonneux. La Lamproie du Nord requiert deux habitats distincts, soit un pour les adultes reproducteurs et un autre, le long du même cours d'eau, pour le développement des ammocètes. La détérioration de l'habitat et la pollution des eaux représentent les principales menaces à la survie des lamproies. La faible fécondité et la mobilité réduite de la Lamproie du Nord font en sorte que cette espèce est peu adaptable aux modifications de son environnement.

Mots-clés : Lamproie du Nord, *Ichthyomyzon fossor*, Petromyzontidae, rapport de situation, Québec.

The Northern Brook Lamprey is endemic to North America. In Quebec, it is restricted to the southernmost part of the province. This lamprey is known from the St. Lawrence River as well as in 11 of its tributaries. It appears to have been extirpated from the Yamaska River where it was collected between 1946 and 1959. It is a nonparasitic fish and its adult size does not usually exceed 160 mm. Larvae, called ammocoetes, and adults are found only in fresh water. Watercourses where it occurs are generally streams and rivers with gravel or sandy bottoms. The Northern Brook Lamprey requires two types of habitats during its life cycle, one for spawning adults and one, along the same watercourse, for the developing ammocoete. Habitat degradation and water pollution are the major threats to the survival of lampreys. The low fecundity and low dispersal abilities of the Northern Brook Lamprey make this species poorly adapted to withstand changes in its environment.

Key Words: Northern Brook Lamprey, *Ichthyomyzon fossor*, Petromyzontidae, status report, Québec.

Le genre *Ichthyomyzon* comprend six espèces qui se regroupent en trois paires, chacune étant composée d'une espèce parasite (espèce souche) et d'une espèce non parasite (espèce satellite; Vladykov et Kott 1979a). La Lamproie du Nord (*Ichthyomyzon fossor*), une espèce non parasite, serait issue de la Lamproie argentée (*Ichthyomyzon unicuspis*), une espèce parasite (Vladykov et Kott 1979a). Toutefois, certaines analyses génétiques récentes ont remis en question le fait que la Lamproie du Nord soit vraiment distincte de la Lamproie argentée (COSEPAC 2007*). La Lamproie du Nord est un petit poisson d'eau douce. Au stade larvaire, les larves, que l'on désigne sous le terme d'ammocètes, vivent enfouies dans les sédiments et se nourrissent par filtration. Au stade adulte, une fois la métamorphose terminée, l'espèce ne conserve pas de tractus intestinal fonctionnel et ne peut ainsi se nourrir. Au cours de sa vie, elle se reproduit seulement une fois et meurt peu de temps après la fraie.

L'aire de répartition de la Lamproie du Nord est limitée à l'Amérique du Nord. Au Canada, on la retrouve au Manitoba, en Ontario et au Québec. Elle a été identifiée au Québec comme espèce susceptible d'être désignée « menacée ou vulnérable ». Au Canada, la Lamproie du Nord n'est pas encore officiellement désignée, mais elle possède le statut d'espèce « préoccupante » attribué par le Comité sur la situation des espèces en péril au Canada (COSEPAC). Un rapport de situation, commandé par cet organisme, a été réalisé en 1991 (Lanteigne 1991*) et une mise à jour a été effectuée en 2007 (COSEPAC 2007*). Le présent article constitue une mise à jour du rapport de situation officiel soumis au ministère des Ressources naturelles et de la Faune du Québec (Fortin et al. 2005*).

Description

La taxinomie des lamproies holarctiques au stade adulte se fonde principalement sur quatre caractères, soit la disposition des dents, le nombre de myomères du tronc, les proportions du corps et la répartition géographique de l'espèce (Vladykov et Kott 1979b*). La longueur totale de la Lamproie du Nord adulte ne dépasse habituellement pas 160 mm (94 à 146 mm;

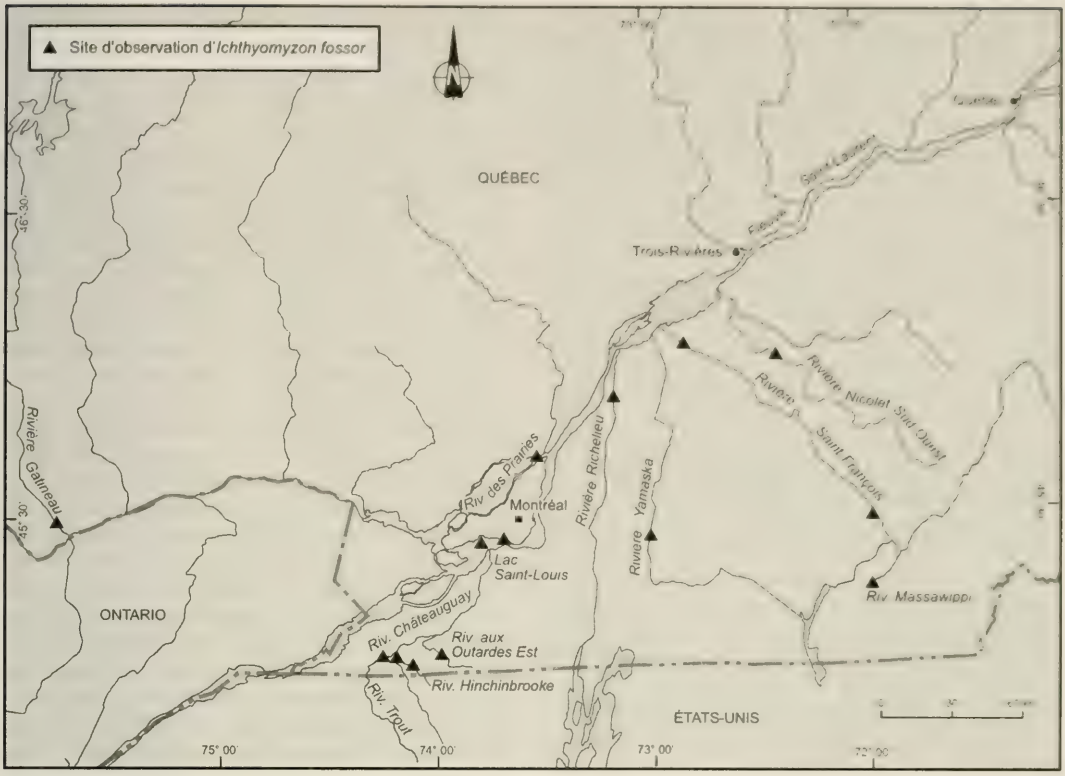

FIGURE 1. Répartition québécoise de la Lamproie du Nord, *Ichthyomyzon fossor*.

Hubbs et Trautman 1937; 128 à 150 mm: Vladykov 1952; 86 à 166 mm: Morman 1979*; 98 à 158 mm: Lanteigne 1981; 130 à 173 mm: Trautman 1981). Son corps est de forme cylindrique et sa tête est courte et dépourvue de mâchoire. Elle possède une bouche ronde en forme de ventouse dont l'ouverture est toujours plus courte que la longueur de la région branchiale. Elle est pourvue de sept paires de branchies. Les yeux sont petits et situés près du haut de la tête. Le nombre de myomères du tronc varie généralement entre 50 et 53 (Lanteigne 1988).

Les dents de l'entonnoir buccal sont peu développées. La lamina supraorale consiste en une dent pourvue de deux pointes alors que la lamina linguale transversale possède entre six et onze petites pointes sur l'arête denticulée (Scott et Crossman 1974). Les dents latérales internes consistent quant à elles en quatre dents unicuspides situées sur chaque côté du disque. Des dents latérales externes et de petites pointes situées dans les champs antérieur et postérieur complètent la dentition. La peau est lisse et ne possède pas d'écailles. L'adulte est bicolore : coloration gris foncé à brune sur le dos et les flancs et grise à blanc argenté sur les parties inférieures (Vladykov 1949*). La surface ventrale a une teinte orangée, particulièrement chez les femelles sexuellement matures (Leach 1940). Le repli anal est plus visible chez la femelle sexuellement mature que chez le mâle et est fusionné à la nageoire caudale (Scott et Crossman 1974). La nageoire dorsale est continue, ce qui la différencie de la Lamproie de l'Est (*Lampetra appendix*).

Répartition

La Lamproie du Nord est une espèce propre à l'Amérique du Nord. Au Canada, elle se retrouve dans le bassin hydrographique de la baie d'Hudson, au Manitoba, et dans le bassin hydrographique des Grands Lacs et du fleuve Saint-Laurent, en Ontario et au Québec (Lanteigne 1992). Aux États-Unis, elle se rencontre dans le bassin du Mississippi depuis le Wisconsin jusqu'à l'Ohio et vers le sud jusqu'au Kentucky (Lanteigne 1992). Il existe aussi une population disjointe au Missouri.

La connaissance de la répartition de la Lamproie du Nord au Québec est très restreinte. Elle se limite à des mentions rapportées dans le cadre de travaux de recherches et d'inventaires multispécifiques. Cette espèce n'a jamais fait l'objet d'un programme d'inventaire systématique et ciblé au Québec, à l'exception des travaux de Vladykov (1952) dans les années 1940 et 1950. Le manque de données sur sa répartition réside, entre autres, dans la nature discrète de ses mœurs tant au stade larvaire qu'adulte, à une faible longévité des individus une fois métamorphosés, à

leur petite taille, à la difficulté d'identifier les lamproies à l'espèce et dans le manque d'inventaires spécifiques. Les populations actuellement connues sont localisées dans le Québec méridional (Figure 1). Elles se retrouvent uniquement en eau douce dans le fleuve Saint-Laurent et dans le cours de certaines rivières tributaires du Saint-Laurent (Tableau 1). Des inventaires ciblés pourraient permettre de confirmer la présence de l'espèce ailleurs dans le fleuve Saint-Laurent et dans certains autres de ses tributaires.

La Lamproie du Nord a déjà été observée en grand nombre dans la rivière Yamaska (près de Saint-Césaire) entre 1946 et 1950 (Vladykov 1952). Malgré un effort intensif au moyen de la pêche électrique, aucun spécimen d'ammocète n'a été observé lors de travaux réalisés en 1990 (Renaud et al. 1995a) et 1992 (C. B. Renaud, non publié) à cette localité. Des quatre stations où Vladykov (1952) a trouvé des spécimens, le site de Saint-Césaire était qualifié d'endroit par excellence pour la Lamproie du Nord. L'espèce pourrait s'être maintenue dans la rivière Saint-François, près de Pierreville, où elle fut observée en 1947, 1951 et 1990. Vladykov (1952) qualifie ce site d'habitat idéal pour les ammocètes, en raison de l'abondance des îles et du substrat de fond favorable. La Lamproie du Nord a de nouveau été observée dans cette rivière en 2003, mais cette fois dans la localité de Bromptonville, à environ 130 km en amont de Pierreville (Desroches et al. 2008).

Biologie générale

Cycle vital

Le cycle vital des lamproies comprend deux stades : le stade larvaire (ammocète) et le stade adulte. Tôt après l'éclosion, la jeune ammocète émerge du nid et migre passivement vers l'aval. Après avoir trouvé un habitat favorable, elle creuse un trou en forme de U dans un substrat plutôt mou où elle demeure généralement cachée. Les ammocètes sont en effet des animaux fouisseurs relativement sédentaires (Potter 1980). Ce stade larvaire persiste de trois à six ans chez la Lamproie du Nord (Hardisty et Potter 1971a). Une fois qu'elle a atteint une certaine taille (moyenne de 131 mm: Leach 1940; moyenne de 114 mm: Purvis 1970), la larve se métamorphose entre les mois d'août et novembre. Le début de la métamorphose est synchrone entre les individus d'une même population; un accroissement rapide et substantiel de la température serait un des facteurs impliqués dans l'initiation de ce phénomène (Potter 1980). D'une durée de 2 à 3 mois, la métamorphose est un lent processus au cours duquel l'individu cesse de se nourrir (Leach 1940). On observe même une réduction de la longueur totale des individus au cours de cette phase. La bouche se transforme en un entonnoir buccal pourvu de dents. Cette période est suivie d'un stade adulte immature qui se déroule généralement entre novembre et février et au cours duquel l'individu est semi-sédentaire (Leach 1940). Une période plus active menant à la maturité sexuelle a lieu de février à mai. L'adulte ne se nourrit jamais. La fraie survient généralement en mai et est suivie quelques jours plus tard par la mort des individus reproducteurs.

Alimentation

Le régime alimentaire des ammocètes se compose principalement de détritus organiques, auxquelles s'ajoutent des algues unicellulaires (principalement des diatomées) et des bactéries (Sutton et Bowen 1994). Les ammocètes utilisent efficacement les détritus organiques pendant les mois les plus chauds lorsque la température des cours d'eau et la qualité des aliments sont plus favorables à l'alimentation, la digestion et la croissance (Sutton et Bowen 1994). Elles se nourrissent très lentement, ce qui leur permettrait d'utiliser au maximum une ressource de faible qualité. Leur taux d'alimentation est d'ailleurs consistant avec le faible métabolisme observé chez ce groupe de poissons (Hill et Potter 1970). Le taux d'alimentation dépend de la température et, à un degré moindre, de la densité des aliments (Moore et Mallatt 1980). La variation dans l'abondance des algues et des bactéries dans l'alimentation des ammocètes correspond à leur disponibilité dans les cours d'eau durant le cycle annuel (Sutton et Bowen 1994). Les bactéries et les algues ne peuvent cependant supporter à elles seules la croissance et le métabolisme des larves; les détritus organiques sont nécessaires à ces fonctions (Moore et Mallatt 1980; Sutton et Bowen 1994). La Lamproie du Nord adulte, tout comme les autres espèces de lamproies non parasites, ne conserve pas de tractus intestinal fonctionnel une fois la métamorphose complétée. Par conséquent, elle ne peut pas manger et n'atteint jamais la taille de l'espèce parasite à laquelle elle est apparentée, soit la Lamproie argentée (Vladykov et Kott 1979b*).

Reproduction

La Lamproie du Nord fraie uniquement en eau douce et atteint généralement l'âge de reproduction à six ans. Les lamproies ne pondent qu'une seule fois dans leur vie et tous les adultes meurent quelques jours après la fraie (Leach 1940). La température de l'eau est le facteur critique qui détermine le début de la période de reproduction chez les lamproies (Hardisty et Potter 1971b; Manion et Hanson 1980). Au Québec, la reproduction a lieu en mai, avec un pic de fraie à des températures de l'eau entre 13 et 16°C (Vladykov 1949*). Comtois et al. (2004) ont capturé une femelle en fraie un 23 juin dans la rivière Gatineau à une température de 19°C. Au Michigan, le pic de reproduction s'étend de la fin mai à la mi-juin, à une température de l'eau moyenne de 18°C (Morman 1979*). Toujours au Michigan, Reighard et Cummins (1916) rapportent une température optimale de l'eau entre 20 et 22°C ; la fraie était rarement observée à des températures inférieures à 18°C. Elle aurait lieu vers la fin mai dans la rivière Tippecanoe, en Indiana (Leach 1940).

TABLEAU 1. Liste des mentions d'observations de la Lamproie du Nord, *Ichthyomyzon fossor*, au Québec.

Cours d'eau	Localité	Année d'observation	Source
Fleuve Saint-Laurent	Rapides de Lachine	1950	Vladykov 1952
Lac Saint-Louis	Pointe-Claire	1941	CDPNQ[a]
Rivière Châteauguay	Athelstan	1990, 1992	Renaud et al. 1995b, 1998
Rivière des Prairies	Lachenaie	1998	CDPNQ
Rivière Gatineau	Gatineau	1999	Comtois et al. 2004
Rivière Hinchinbrooke	Hinchinbrooke	1976	MRNF[b]
Rivière Massawippi	North Hatley	1995	Desroches et al. 2008
Rivière Nicolet Sud-Ouest	Mitchell Station	1951	Vladykov 1952
Rivière aux Outardes Est	Franklin	2002	J. Dubé, communication personnelle
Rivière Richelieu	Saint-Roch-de-Richelieu	1990	Renaud et al. 1995b
Rivière Saint-François	Pierreville	1947, 1951	Vladykov 1952
	Pierreville	1990	Renaud et al. 1995a
	Bromptonville	2003	Desroches et al. 2008
Rivière Trout	Huntingdon	1976	CDPNQ
Rivière Yamaska	Saint-Césaire	1946 – 1950	Vladykov 1952
		1959	CDPNQ

En plus de la température de l'eau, deux autres facteurs sont essentiels au succès de ponte, soit un substrat adéquat et un courant uniforme et unidirectionnel s'écoulant au-dessus du nid (Manion et Hanson 1980; Lanteigne 1992). La Lamproie du Nord fraie dans des ruisseaux et des petites rivières sur fond de gros gravier, de galets (25 à 152 mm de diamètre) et de sable (Reighard et Cummins 1916; Scott et Crossman 1974). Bien que la fraie des lamproies soit généralement associée à des habitats peu profonds sans couvert de protection, il est maintenant admis que les espèces du genre *Ichthyomyzon* se reproduisent aussi sous un couvert de grosses roches ou de débris ligneux (Cochran et Gripentrog 1992). Ce comportement permettrait aux lamproies de se reproduire dans des milieux où l'eau est plus profonde et où le courant serait autrement trop fort pour frayer dans des milieux ouverts. Il réduirait aussi la vulnérabilité des reproducteurs à certains types de prédateurs (Cochran et Gripentrog 1992). Hardisty et Potter (1971b) rapportent que les cours d'eau typiques des lamproies de ruisseaux ont une vitesse du courant située entre 0,3 et 0,5 m/s dans les aires de fraie.

Les adultes ne semblent pas migrer en masse vers les aires de fraie (Leach 1940). Une fois arrivés sur les lieux, les reproducteurs se regroupent habituellement dans une aire restreinte (Scott et Crossman 1974). Les mâles amorcent alors la nidification (Manion et Hanson 1980; Moyle et Cech 2004). Ils établissent leurs nids en déplaçant de petits cailloux à l'aide de leur bouche afin de créer une légère dépression. Ils déplacent ensuite le sable à l'aide de mouvements vigoureux du corps (Hardisty et Potter 1971b). Le nid a un diamètre d'environ 7 à 10 cm (Scott et Crossman 1974). La profondeur se situe généralement entre 20 et 46 cm, de la surface de l'eau jusqu'au fond du nid (Hardisty et Potter 1971b; Scott et Crossman 1974). Leach (1940) rapporte qu'une femelle pond environ 1 195 œufs, mais cette donnée n'est basée que sur un échantillon composé de deux femelles. Pour sa part, Vladykov (1951) mentionne une moyenne de 1524 œufs (1115 à 1979), à partir de neuf spécimens récoltés au Québec. Le diamètre moyen d'un œuf se situe entre 1,0 et 1,2 mm (Vladykov 1951; Scott et Crossman 1974). Après la fertilisation, les œufs sont recouverts du substrat environnant le nid (Hardisty et Potter 1971b). Les oeufs éclosent 2 à 4 semaines plus tard (Leach 1940).

Déplacements

La répartition des lamproies le long d'un cours d'eau est le résultat de deux types de comportements liés aux déplacements des adultes et des larves. Le premier correspond à la migration vers l'amont des adultes reproducteurs aux aires de fraie. La migration des lamproies non parasites se ferait sur des distances beaucoup plus courtes que chez les espèces parasites (Hardisty et Potter 1971b). Le deuxième type de déplacements concerne la migration des ammocètes vers l'aval, là où les conditions d'envasement et de courant sont plus favorables à l'alimentation et à l'enfouissement dans le substrat. Cette migration est en partie passive (Potter 1980). Le déplacement des ammocètes est fonction de leurs mouvements, des conditions hydrographiques et hydrologiques locales, de la température de l'eau, de la saison, de la stabilité et de la nature du fond du cours d'eau, de la qualité de l'eau et de leur densité en relation avec la qualité de l'habitat (Hardisty et Potter 1971a; Morman et al. 1980; Potter 1980). Certains auteurs suggèrent que cette migration est minimale, tout particulièrement dans les cours d'eau où les gradients sont faibles, où l'écoulement est stable et où les habitats sont propices

(Morman et al. 1980). Elle pourrait cependant être plus importante dans les cours d'eau où les gradients sont plus importants, les ammocètes plus âgées étant de plus en plus prédominantes vers l'aval (Hardisty et Potter 1971a; Potter 1980). Bien que les ammocètes nagent relativement bien, il est improbable qu'elles puissent soutenir cette grande vitesse au cours d'une longue période (Potter 1980). Elles peuvent cependant nager à contre-courant, si ce dernier est faible (Hardisty et Potter 1971a). Les déplacements volontaires des ammocètes s'effectueraient principalement la nuit (Potter 1980), ce qui réduirait l'impact des prédateurs diurnes. La migration vers l'aval des individus métamorphosés se réalise aussi généralement la nuit et est influencée par le débit et la température du cours d'eau (Potter 1980).

Parasites et maladies

À notre connaissance, aucune étude n'a décrit la nature et la fréquence des parasites et des maladies spécifiques à la Lamproie du Nord. L'espèce est probablement susceptible à un bon nombre de maladies non spécifiques que l'on retrouve chez les autres poissons d'eau douce du Québec (Uhland et al. 2000). Chez la Lamproie marine (*Petromyzon marinus*), Wilson et Ronald (1967) ont observé que les adultes capturés en lac avaient un taux d'infection parasitaire (19 %) beaucoup plus faible que les spécimens qui retournaient en rivière pour frayer (53 %).

Longévité

Chez les lamproies, la durée du stade adulte est beaucoup plus courte que celle du stade larvaire. Dans le cas de la Lamproie du Nord, les adultes ne vivent qu'environ 6 mois, tandis que les ammocètes ont besoin de 3 à 6 ans pour arriver à leur métamorphose, selon le lieu et la nourriture (Okkelberg 1922; Leach 1940; Purvis 1970). L'âge maximum d'un adulte serait donc d'au plus 7 à 8 ans. La durée précise du stade larvaire est difficile à déterminer avec assurance car l'estimation est basée sur des classes de fréquence de longueur totale des individus (Leach 1940; Scott et Crossman 1974; Potter 1980).

Habitats

La Lamproie du Nord habite généralement les ruisseaux et les rivières à fond graveleux ou sablonneux (Jyrkkanen et Wright 1979; Morman 1979*). Au Québec, on la retrouve aussi dans le fleuve Saint-Laurent. Elle semble éviter les eaux stagnantes et les lacs (Hubbs et Trautman 1937). Dans le bassin hydrographique du lac Supérieur, Schuldt et Goold (1980) ont observé la Lamproie du Nord dans des cours d'eau de taille intermédiaire où le débit moyen estival variait de 0,3 à 28,3 m^3/s; l'espèce était commune dans plusieurs cours d'eau aux eaux turbides et habitait les régions de la tête des eaux. On ne retrouve la Lamproie du Nord qu'en eau douce; elle ne tolère aucunement la salinité (Vladykov 1949*). La rivière Yamaska, près de Saint-Césaire, représentait un habitat typique de la Lamproie du Nord selon Vladykov (1952).

En fonction de l'âge des individus, la Lamproie du Nord requiert deux habitats distincts le long d'un cours d'eau donné, soit un pour les adultes reproducteurs et un autre pour le développement des ammocètes. Les adultes reproducteurs ont besoin de petits cours d'eau aux eaux claires et à gradient topographique élevé, avec présence de rapides et un fond de gravier et de sable (Trautman 1981). Quant aux ammocètes, elles préfèrent la portion des cours d'eau à courant plus lent, là où le substrat est propice à l'enfouissement (substrat mou; Potter et al. 1986). Ce substrat renferme souvent un contenu élevé en matériel organique (Hardisty et Potter 1971a; Potter et al. 1986; Beamish et Lowartz 1996). La composition des sédiments, dont la taille des particules ainsi que l'hétérogénéité, constitue un facteur important dans la sélection de l'habitat (Hardisty et Potter 1971a; Anderson et White 1988; Beamish et Lowartz 1996). Les ammocètes éviteraient les fonds composés principalement de très petites ou de grosses particules, le fond étant trop compact dans le premier cas et les particules trop lourdes pour être délogées par les larves dans le second (Beamish et Lowartz 1996). La taille idéale correspondrait à du sable mi-fin.

Au Michigan, Morman (1979*) a observé que la Lamproie du Nord était plus tolérante à l'eau chaude que les autres espèces étudiées. Les plus grandes densités d'ammocètes se retrouvaient habituellement dans les sections les plus chaudes des cours d'eau. Ce type de milieux serait généralement non propice à la présence de l'Omble de fontaine (*Salvelinus fontinalis*; Vladykov 1949*). Les ammocètes sont photophobiques, ce qui expliquerait pourquoi l'ombre est un facteur qui influence significativement leur répartition (Potter et al. 1986). La quantité de chlorophylle *a* à la surface du substrat serait aussi une variable environnementale importante expliquant la densité des larves de lamproie (Potter et al. 1986). Cette observation reflète bien l'importance des diatomées et autres microalgues dans le régime alimentaire des ammocètes qui évitent généralement les eaux stagnantes ou trop riches en matière organique, là où la teneur en oxygène est faible (Potter 1980).

Dynamique des populations

Les connaissances sur la dynamique des populations de la Lamproie du Nord sont limitées. La fécondité de cette espèce fut caractérisée au Québec par Vladykov (1951) et est considérée faible par rapport aux autres espèces de lamproies étudiées. La survie des œufs dans les nids n'a pas été déterminée chez la Lamproie du Nord, mais chez la Lamproie marine, celle-ci est élevée, pouvant atteindre 90 % (Manion et Hanson 1980). À partir d'un échantillon de 627 larves de Lamproie du Nord, Purvis (1970) a observé un rapport des sexes de 1 : 1 dans un tributaire du lac Supérieur, au Michigan. Chez les adultes reproduc-

teurs, il semble que le rapport des sexes favorise les mâles (75 %, Purvis 1970; 71 %, Jyrkkanen et Wright 1979). Ce phénomène est observé chez plusieurs autres espèces de lamproies non parasites (Potter 1980).

Chez la Lamproie du Nord, comme chez d'autres espèces de lamproies, une classe d'âge peut contribuer à plusieurs cohortes de reproducteurs. En effet, seule une fraction d'une classe d'âge se métamorphose une année donnée, les autres individus de la même classe se métamorphosant au cours des années suivantes (Purvis 1970). Ce recrutement de différentes classes d'âge à la population reproductrice pourrait expliquer les fluctuations de populations observées chez la Lamproie de Planer (*Lampetra planeri*), une espèce européenne (Hardisty 1961). La température de l'eau et la disponibilité de nourriture seraient des facteurs déterminants pour la croissance des ammocètes (Hardisty et Potter 1971a). La croissance variait beaucoup entre les classes d'âge étudiées par Purvis (1970). L'auteur suggère que cette différence est principalement causée par une forte diminution de la densité de la population consécutive à des traitements chimiques avec des lampricides. Il en résulterait une diminution de la compétition pour la nourriture et l'espace et une augmentation de la croissance dans la population résiduelle.

Pressions sur l'espèce, facteurs limitants et adaptabilité

La détérioration de l'habitat constitue probablement la principale pression sur l'espèce (Vladykov 1973; Renaud 1997). Différents types de pollution, seule ou en combinaison avec d'autres facteurs, restreignent la répartition des lamproies (Morman et al. 1980; Renaud 1997). La pollution de l'eau liée au développement agricole semble être la principale cause de la disparition apparente de la Lamproie du Nord de la rivière Yamaska, au niveau de Saint-Césaire (Renaud et al. 1995a). Les programmes de contrôle chimique de la Lamproie marine introduite dans les bassins hydrographiques des lacs Huron, Michigan et Supérieur (Smith et Tibbles 1980) ont affecté les populations locales d'autres espèces de lamproies, dont la Lamproie du Nord (Schuldt et Goold 1980). Les larves de cette espèce ainsi que de la Lamproie argentée ont disparu de 41 des 81 cours d'eau traités du bassin hydrographique du lac Supérieur qu'elles fréquentaient jadis, tant au Canada qu'aux États-Unis (Schuldt et Goold 1980). Le lampricide utilisé, le 3-trifluorométhyl-4-nitrophénol (TFM), est destiné à tuer les larves avant leur métamorphose. Le genre *Ichthyomyzon* serait de susceptibilité intermédiaire au TFM (Davis 1970).

La Lamproie du Nord était utilisée autrefois comme appât pour la pêche sportive (Vladykov 1973). Vladykov (1952) mentionne des récoltes totales annuelles d'environ 300 000 ammocètes pour l'ensemble du Québec dans les années 1940 et 1950, toutes espèces confondues. L'impact qu'a eu cette pratique sur les populations québécoises est cependant inconnu. Cette utilisation pour la pêche sportive est maintenant interdite au Québec. L'accumulation de sédiments transportés par l'eau jusqu'aux aires de fraie, les barrages et autres obstacles bloquant les remontées d'adultes reproducteurs et l'abaissement du niveau de l'eau, lesquels constituent une menace pour la survie des larves dans leurs abris, représentent d'autres pressions sur l'espèce (Scott et Crossman 1974; Morman et al. 1980; Lanteigne 1992; Renaud 1997).

La mortalité peut parfois être élevée au tout début du cycle vital (Potter 1980). Diverses espèces de poissons ont en effet été observées en train de se nourrir d'œufs de lamproies ou de très jeunes larves (Hardisty et Potter 1971a; Vladykov 1973; Potter 1980; Lanteigne 1992). Les jeunes larves sont aussi susceptibles à la prédation lorsqu'elles quittent le nid et migrent vers l'aval (Hardisty et Potter 1971a; Potter 1980). La prédation sur les ammocètes plus âgées ne semble cependant pas être un facteur de mortalité important car elles demeurent enfouies (Potter 1980). Trautman (1981) considère les ammocètes et les adultes comme très vulnérables à la prédation par d'autres poissons. Par ailleurs, des cas de prédation sur les adultes reproducteurs ont été rapportés pour une panoplie de prédateurs tels que belette, chien domestique, couleuvre d'eau, goéland, héron, rat musqué, raton laveur et renard (Morman et al. 1980). Les lamproies au nid sont davantage susceptibles à la prédation, car elles sont plus exposées dans des eaux relativement peu profondes.

La compétition interspécifique, les parasites et les maladies ne semblent pas influencer de façon importante la répartition et l'abondance de la Lamproie marine (Morman et al. 1980). L'importance de ces derniers facteurs pour la Lamproie du Nord reste inconnue. La faible fécondité de la Lamproie du Nord suggère qu'il pourrait être plus difficile pour elle de se rétablir à la suite d'un déclin des populations (Schuldt et Goold 1980; Lanteigne 1992). Aussi, la mobilité restreinte de l'espèce limite ses chances de pouvoir recoloniser les cours d'eau où elle aurait disparu. Ces éléments font de la Lamproie du Nord une espèce peu adaptable aux modifications de son environnement.

Importance particulière de l'espèce

Même si les lamproies constituent un mets de choix dans certaines régions hors Québec (Moyle et Cech 2004), ce type de poissons est actuellement sans grande valeur économique. N'étant pas un poisson parasite, la Lamproie du Nord ne présente pas le danger de blesser ou de tuer d'autres espèces de poissons, au contraire de la Lamproie marine par exemple. La Lamproie du Nord présente cependant un intérêt certain d'ordre scientifique et écologique. Cette espèce fait en effet partie d'un groupe de poissons parmi les plus primitifs (Forey et Janvier 1993) et offre ainsi l'occasion d'étudier l'évolution des poissons et les raisons pour lesquelles les lamproies ont continué à se maintenir dans un environnement en perpétuel change-

ment (Lanteigne 1992; Moyle et Cech 2004). Les lamproies sont également utiles comme animaux de laboratoire, particulièrement en neurobiologie (Moyle et Cech 2004). Les ammocètes filtrent différents types de micro-organismes et constituent une source de nourriture pour plusieurs espèces de poissons, d'où leur importance dans la chaîne alimentaire (Vladykov 1973). La présence de ce poisson dans le Québec méridional contribue aussi à la biodiversité des ruisseaux et des rivières. Comme les ammocètes sont des poissons relativement sédentaires passant une bonne partie de leur vie enfouis dans les sédiments, elles représentent ainsi des bio-indicateurs potentiels des niveaux de contaminants persistants dans les milieux d'eau douce. Une étude réalisée au Québec a démontré que les ammocètes, et notamment celles de la Lamproie du Nord, sont aussi appropriées que les mollusques bivalves adultes comme baromètres des niveaux de contaminants organochlorés (Renaud et al. 1995b). Elles sont considérées comme un bon bio-indicateur de la contamination au mercure en plus de pouvoir indiquer les différences dans les niveaux de contamination en métaux entre les rivières (Renaud et al. 1998).

Bilan de la situation

Taille des populations et tendances démographiques

Aucune estimation de la taille totale des populations de la Lamproie du Nord n'est disponible pour le Québec ou ailleurs dans son aire de répartition (COSEPAC 2007*). On ne connaît donc pas sa situation exacte ni la tendance démographique des populations identifiées à ce jour. Seules des données ponctuelles de taille de populations sont disponibles, lesquelles sont présentées ci-après.

À Saint-Césaire, dans la rivière Yamaska, 61 adultes et 842 ammocètes ont été capturés entre 1946 et 1950, dont 721 ammocètes entre le 27 juillet et le 30 août 1949, au cours d'une étude menée par Vladykov (1952). En dépit d'un effort de pêche intensif, aucun spécimen n'a été capturé au même endroit en 1990 et 1992 (Renaud et al. 1995a; C. B. Renaud, non publié). L'état actuel de l'espèce dans l'ensemble de la rivière reste à préciser.

Deux individus métamorphosés et plusieurs ammocètes ont été recensés dans la rivière Saint-François près de Pierreville entre 1947 et 1951 (Vladykov 1952). Une étude réalisée en 1990 a permis la récolte de deux ammocètes dans cette localité, près de l'île Cartier (Renaud et al. 1995a). L'espèce était donc toujours présente à l'époque, bien qu'aucune donnée ne soit disponible quant à l'abondance de la population. La situation actuelle à cette localité demeure inconnue. Toutefois, l'espèce fut de nouveau observée dans cette rivière le 26 août 2003 à Bromptonville, soit à 130 km en amont de la localité de Pierreville (Desroches et al. 2008). Il s'agissait d'une ammocète vivante trouvée dans un bassin. De même, environ douze ammocètes mortes et deux vivantes ont été observées le 20 septembre 1995 dans la rivière Massawippi, un tributaire de la rivière Saint-François, à North Hatley (Desroches et al. 2008). Quelques secteurs du bassin versant de la rivière Saint-François semblent donc propices à la Lamproie du Nord.

Une seule femelle adulte a été capturée dans la rivière Gatineau en 1999 (Comtois et al. 2004). Un seul individu a aussi été capturé dans la rivière aux Outardes Est en 2002 (Jean Dubé, communication personnelle). La mention de la localité des Rapides de Lachine concerne six ammocètes capturées le 26 juillet 1950 alors que celle du bassin de la rivière Nicolet (rivière Nicolet Sud-Ouest) se rapporte à une ammocète notée le 22 juillet 1951 (Vladykov 1952). Respectivement trois et six individus de sexe et de stade indéterminé ont été rapportés sur les rivières Trout et Hinchinbrooke en 1976 par le Centre de données sur le patrimoine naturel du Québec (CDPNQ) et le ministère des Ressources naturelles et de la Faune du Québec, ainsi qu'un adulte en 1998 dans la rivière des Prairies par le CDPNQ. Finalement, la mention de 1990 de la rivière Richelieu concerne cinq ammocètes (Renaud et al. 1995b).

Menaces à la survie de l'espèce au Québec

La détérioration de l'habitat et la pollution des eaux semblent représenter les principales menaces à la survie des lamproies (Renaud 1997; Moyle et Cech 2004), incluant la Lamproie du Nord. La pollution de la rivière Yamaska, associée à une agriculture intensive et à des rejets industriels et urbains, apparaît comme une cause possible de l'absence de mention de l'espèce dans la localité de Saint-Césaire en 1990 et 1992 (Renaud et al. 1995a; C. B. Renaud, non publié). L'utilisation intensive de l'herbicide atrazine appliqué dans la culture du maïs serait également en cause. Lessivé dans la rivière suite aux fortes pluies, ce produit chimique réduirait de façon importante le phytoplancton dont se nourrissent les ammocètes (Renaud et al. 1995a). On retrouve également de nombreux autres pesticides dans la rivière Yamaska et plusieurs de ses tributaires, dont le métolachlore, la cyanazine et le dicamba (Gouvernement du Québec 1998*). Il n'est pas rare de découvrir plus de six pesticides différents au même endroit. La prédominance de la culture du maïs qui nécessite régulièrement l'application de ces produits expliquerait en bonne partie cette situation. Malgré tous les efforts qui ont été déployés au cours des dernières années, la rivière Yamaska présente toujours la pire qualité d'eau au Québec. Le portrait n'est pas plus réjouissant dans le secteur particulier de Saint-Césaire (Gouvernement du Québec 1998*).

D'autres rivières où l'espèce fut observée telles que les rivières Richelieu et Nicolet, sont aussi d'une qualité relativement mauvaise (Gouvernement du Québec 1993*, 1995*). En fait, depuis 1992, le ministère du Développement durable, de l'Environnement et des Parcs mène un programme de suivi annuel des

pesticides dans quatre cours d'eau des régions agricoles où la culture du maïs est importante (Gouvernement du Québec, 2006*). Ces sont les rivières Chibouet (bassin de la rivière Yamaska), des Hurons (bassin de la rivière Richelieu), Saint-Régis (affluent direct du fleuve Saint-Laurent) et Saint-Zéphirin (bassin de la rivière Nicolet). Des pesticides ont régulièrement été détectés durant l'été dans ces rivières. Les substances trouvées le plus souvent sont l'atrazine, le métolachlore, le bentazone, le dicamba, le 2,4-D et le diméthénamide. Ces substances représentent autant de menaces pour la Lamproie du Nord en affectant la qualité de l'eau.

Une autre menace importante à la survie de la Lamproie du Nord au Québec est la disparition des bandes riveraines qui provoque l'érosion des sols et augmente la sédimentation dans les lits des cours d'eau, altérant ainsi les aires de fraie. Ce phénomène constitue une menace importante pour les lamproies (Moyle et Cech 2004). Les bandes riveraines boisées, par leur rôle de filtres et de stabilisateurs des berges, protègent aussi les cours d'eau contre les apports en fertilisants et en pesticides (Société de la faune et des parcs du Québec 2003*). Elles procurent aussi de l'ombre, élément important de l'habitat des ammocètes (Potter et al. 1986). Les superficies requises pour épandre les surplus de lisier de porc et les monocultures comme celle du maïs sont, entre autres, responsables de la disparition des bandes riveraines (Société de la faune et des parcs du Québec 2003*). Les régions de la Montérégie, du Centre-du-Québec et de Chaudière-Appalaches sont particulièrement touchées à cet égard.

La croissance de l'industrie porcine a provoqué une surcharge de fumier et de ses substances polluantes. L'excès de fertilisant, et tout particulièrement le phosphore, touche directement la qualité de l'habitat de la Lamproie du Nord via l'eutrophisation des cours d'eau (Société de la faune et des parcs du Québec 2003*). Cette menace touche potentiellement les cours d'eau de la Montérégie, du Centre-du-Québec et de Chaudière-Appalaches, lesquelles ont été particulièrement touchées par la production porcine au cours des dernières décennies, comme par exemple les rivières Nicolet, Richelieu, Saint-François et Yamaska.

D'autres menaces potentielles pour l'habitat de la Lamproie du Nord concernent le redressement des petits cours d'eau, lequel pourrait endommager l'habitat utilisé par les adultes reproducteurs, ainsi que la présence d'obstacles (ex. barrages) à la libre circulation de l'espèce entre ses habitats de reproduction et de développement des ammocètes.

Statut actuel et protection légale

La Lamproie du Nord a été identifiée au Québec comme espèce susceptible d'être désignée « menacée ou vulnérable » en vertu de la *Loi sur les espèces menacées ou vulnérables*. Au Canada, la Lamproie du Nord figure à l'annexe 3 de la *Loi sur les espèces en péril* à titre d'espèce « préoccupante », désignation donnée par le COSEPAC en 1991 et une mise à jour a été effectuée en 2007 (COSEPAC 2007*). En tant qu'espèce de poissons, la Lamproie du Nord est protégée au Québec en vertu de la *Loi sur la conservation et la mise en valeur de la faune*. L'habitat de l'espèce n'est protégé au Québec que sur les terres publiques par l'application du *Règlement sur les habitats fauniques*, de même qu'à l'échelle fédérale, tant sur les terres privées que sur les terres publiques, en vertu de la *Loi sur les pêches* et la *Politique de gestion de l'habitat du poisson*. Au Québec, la *Loi sur la qualité de l'environnement* et la *Politique de protection des rives, du littoral et des plaines inondables* s'appliquent également à l'habitat de l'espèce autant en terres publiques que privées.

Évaluation

Il existe un urgent besoin de réaliser des travaux d'inventaire spécifiques et d'effectuer un suivi des populations de Lamproie du Nord au Québec, en donnant priorité aux sites actuellement connus. Des vérifications s'imposent pour savoir si l'espèce a survécu dans ces cours d'eau et, le cas échéant, si ces populations et leurs habitats sont en bonne santé. Une estimation de la taille des populations serait aussi souhaitable. Cette initiative devrait être considérée comme prioritaire dans le contexte de la conservation de l'espèce au Québec. Actuellement, on estime que 55 % des espèces de lamproies de l'hémisphère nord sont en difficulté (Renaud 1997).

Nos connaissances actuelles sur la situation de la Lamproie du Nord au Québec vis-à-vis sa répartition et l'état de ses populations ne nous permettent pas de nous prononcer quant à la catégorie de conservation à attribuer à cette espèce. En effet, contrairement à sa situation dans la région des Grands Lacs où l'effort de pêche est connu à cause du programme de contrôle de la Lamproie marine, *Petromyzon marinus*, permettant ainsi de déterminer les tendances des populations de toutes les espèces de lamproies de cette région, les mentions de la Lamproie du Nord au Québec ne sont pas le résultat d'un suivi de longue durée mais plutôt la conséquence de travaux d'inventaire ichtyologique d'ordre généraux (e.g. Comtois et al. 2004). De plus, ce n'est que tout récemment (Desroches et al. 2008) que la présence de la Lamproie du Nord est connue bien en amont de la rivière Saint-François, à environ 130-165 km de la localité originale de Pierreville (Vladykov 1952), une indication de notre manque d'inventaire à l'échelle de la province. COSEPAC (2007*) attribua à la Lamproie du Nord de la région des Grands Lacs et du haut Saint-Laurent le statut d'espèce « préoccupante » en raison des menaces dues à l'épandage de larvicides sur environ 50% de son aire de répartition (i.e. la région des Grands Lacs). Nous souhaitons donc que notre article serve de point de référence pour des études de suivi sur la Lamproie du Nord au Québec et lançons un appel pour celles-ci.

Remerciements

Nous remercions J. Dubé (ministère des Ressources naturelles et de la Faune) pour sa contribution de données inédites ainsi qu'Alain Chouinard et Marie-France La Rochelle pour la réalisation de la carte.

Seasonal Variation in Sex Ratios Provides Developmental Advantages in White-tailed Deer, *Odocoileus virginianus*

Sarah T. Saalfeld[1], Stephen S. Ditchkoff[2], John J. Ozoga[3], and Michael S. Mitchell[4]

Saalfeld, Sarah T., Stephen S. Ditchkoff, John J. Ozoga, and Michael S. Mitchell. 2008. Seasonal variation in sex ratios provides developmental advantages in White-tailed Deer, *Odocoileus virginianus*. Canadian Field Naturalist 121(4):412-419.

Since Trivers and Willard first proposed their hypothesis concerning the adaptive advantages of producing a particular offspring sex in relation to maternal condition in 1973, it has been at the forefront of scientific research concerning sex ratios with most subsequent studies focusing on maternal condition as a key contributor to variations in sex ratios. Another factor that could greatly influence sex ratios, although has been only infrequently examined in mammalian species, is birth date. We investigated how birth date influenced offspring sex ratios in White-tailed Deer (*Odocoileus virginianus*). Since date of birth can greatly influence an individual's fitness and reproductive success, we suggest that birth date may be an alternative strategy in determining offspring sex ratios. Since it has been shown that the lifetime reproductive fitness of a mother can be increased by producing a particular sex during a particular time, we hypothesized that more male offspring should be born earlier in the season due to their increased reproductive potential from being born at this time. Offspring born earlier will have a head start in development and therefore have greater potential for increased body size and dominance later in life, traits that greatly influence male reproductive success. In this study, we found that maternal condition did not affect offspring sex ratio in a captive population of White-tailed Deer in Michigan; however, birth date did. We found that more males tended to be born during the second and fourth birthing periods, while more females were born during the first, third and fifth periods. In addition, we found that males born earlier in the season had greater mass the following spring than those born later, a trend that was not as dramatic in females. These results lend moderate support to our hypothesis that in White-tailed Deer offspring sex will tend to vary according to timing of birth and relative reproductive advantages gained by a particular sex being born at that time.

Key Words: White-tailed Deer, *Odocoileus virginianus*, birth date, early bird hypothesis, local resource competition, seasonality, secondary sex ratio, temporal variation, Trivers-Willard hypothesis.

The potential for offspring sex ratios to differ from parity has been well documented in a number of mammalian species, including White-tailed Deer (*Odocoileus virginianus*) (Verme and Ozoga 1981; Kojola and Eloranta 1989; Kucera 1991; Landete-Castillejos et al. 2001; Landete-Castillejos et al. 2004; Sheldon and West 2004). This strategy could enhance the lifetime fitness of a female by producing the sex with the greatest potential reproductive value. Some factors shown to influence this variation include: maternal age, condition, social status, and habitat quality. Trivers and Willard (1973) proposed that females of sexually dimorphic, polygynous species in good condition would benefit more from producing sons, because the mother's condition would more strongly influence the future reproductive success of sons than daughters. Conversely, females in poor condition would benefit most by producing daughters, since female offspring require less maternal investment (i.e., milk production) and will likely reproduce regardless of maternal condition. Poor quality male offspring likely will not develop the physical characteristics necessary to compete successfully for females later in life. Assumptions for the Trivers and Willard hypothesis include: condition of offspring is correlated with condition of the mother after the parental investment period, condition of the young following the parental investment period will carry over to adulthood, and conditional advantages will differentially benefit male offspring in reproductive success (Trivers and Willard 1973). Since most ungulate species are polygynous, sexually dimorphic species which commonly exhibit these three assumptions (Hewison and Gaillard 1999), numerous studies have been conducted to test the Trivers-Willard hypothesis. In several of these studies, support for the Trivers-Willard hypothesis has been documented, where older or more dominant individuals gave birth to more males, and younger or subordinate females gave birth to more females (Landete-Castillejos et al. 2001; Landete-Castillejos et al. 2004; Sheldon and West 2004).

Despite the many findings that support Trivers and Willard (Landete-Castillejos et al. 2001; Landete-Castillejos et al. 2004; Sheldon and West 2004), numerous studies have reported data that seem to contradict their hypothesis. In a review of published papers on

the genus *Odocoileus*, Verme (1983) found that more males were produced by younger females, females in poor condition, and females in areas of poor habitat quality. Similarly, Mendl et al. (1995) discovered that more female offspring were produced by dominant females in domestic pigs (*Sus scrofa*). These contradicting trends have been explained by alternative hypotheses for biased sex ratios, including: the local resource competition hypothesis (Clark 1978), the advantaged daughter hypothesis (Hiraiwa-Hasegawa 1993), and the advantaged matriline hypothesis (Leimar 1996). According to the advantaged daughter and the advantaged matriline hypotheses, mothers are better able to influence the reproductive success of daughters rather than sons (e.g., by the transfer of rank and/or access to high quality resources). Therefore, these hypotheses propose that high quality females are more likely to produce females than males. Conversely, the local resource competition hypothesis states that local resources rather than maternal condition drive biases in sex ratios. In matriarchal species, Clark (1978) proposed that females in good condition will produce more female offspring, whereas females in poor condition will invest more in male offspring. This is because female offspring normally establish home ranges that overlap their mother's home range, while males tend to disperse, creating less competition for resources in the future.

While they differ, all of these hypotheses focus on maternal condition as the driving factor in offspring sex ratios of mammals. Another factor that should greatly influence reproductive potential of offspring and offspring sex ratios is birth date. In many sexually dimorphic species, it is believed that time at birth differentially affects the ability of a particular sex to reproduce during its first and subsequent years (Suttie 1983; Clutton-Brock et al. 1984; Kruuk et al. 1999; Festa-Bianchet et al. 2000). Therefore, having biased sex ratios of offspring according to birth date could increase a female's lifetime fitness. A number of avian species have been shown to have varying sex ratios seasonally, including the Northern Goshawk (*Accipiter gentiles*: Byholm et al. 2002), European Kestrel (*Falco tinnunculus*: Pen et al. 1999), Common Sandpiper (*Actitis hypoleucos*: Andersson et al. 2003), American Kestrel (Smallwood and Smallwood 1998; *F. sparverius*: Griggio et al. 2002), Spotted Starling (*Sturnus unicolor*: Cordero et al. 2001), and Little Grassbirds (*Megalurus gramineus*: McIntosh et al. 2003). In their work with a nonmigratory population of American Kestrels, Smallwood and Smallwood (1998) found more male-biased sex ratios earlier in the season compared to later and proposed that males that fledged earlier could find nest sites and defend territories better than males that fledged later. Griggio et al. (2002) found the same results in a migratory population of American Kestrels, with more males born earlier in the season. Similarly, it was determined that the sex ratio variation could be due to acquisition of nest sites that were limited for this population. In contrast, competition for mates seemed the most likely explanation for male-biased sex ratios early in season in the Common Sandpiper, because males born earlier have an advantage in obtaining mates (Andersson et al. 2003). Although the explanations for these trends differ, they suggest that varying offspring sex ratios by birth date has an adaptive advantage to a mother by enhancing her own future fitness. Smallwood and Smallwood (1998) coined this trend the "Early Bird Hypothesis" and predicted that the sex which gains the greatest advantage by hatching earlier is selected for in early conception dates in avian species.

The Early Bird Hypothesis (Smallwood and Smallwood 1998), however, has not been evaluated in mammals. While it has been demonstrated that older individuals tend to give birth earlier (Johns et al. 1977; Festa-Bianchet 1988; Christley et al. 2002), older individuals tend to produce more male offspring (Landete-Castillejos et al. 2004), and offspring born earlier are more likely to survive due to increased food resources (Festa-Bianchet 1988; Singh et al. 1990; Festa-Bianchet et al. 1997; Côté and Festa-Bianchet 2001), the link to differential sex ratios based on birth date has not been well documented in mammalian species. We hypothesize that birth date is a driving factor in offspring sex ratios, with females producing more male offspring earlier in the breeding season and increasing production of females as the season progresses. Because offspring born earlier should have a longer period of time to grow before their first winter, more males should be produced at this time period because of the relative importance of size on future reproductive success in males and females.

Materials and Methods

We analyzed data from the Cusino enclosure, a 252-ha enclosure located near Shingleton, 46°21'N, 86°28'W, in Michigan's Upper Peninsula from 1973 through 1984 (excluding 1974). The enclosure consisted mainly of northern hardwoods, mixed hardwood-conifer stands, and pine (*Pinus sp.*) plantation. Due to initial overbrowsing and subsequent condition decline, deer were supplementally fed ad libitum year-round with a pelleted ration beginning in 1972 and were fed throughout the study period. Following this, deer were documented to be in good physical condition, even during winter months (Ozoga and Verme 1982). Initially (1972-1976), no deer were intentionally removed from the enclosure; however, to ensure a stable population, the number of individuals within the enclosure was maintained at approximately 40 individuals with the removal of most fawns and older individuals each year starting in 1977 (Ozoga and Verme 1982). Although some potential bias could result from the removal of such individuals, in a natural population, most mortality would occur among

the removed age classes (i.e., young and old individuals). Therefore, we assume the conditions within the enclosure are representative of a natural population, and in fact, the ages of mothers observed in this study (i.e., 1 to 13 years of age) falls within the natural range of breeding females (e.g., ages of pregnant deer darted in Alabama ranged from 1 to 13 year of age as determined by annuli in the cementum; S. T. Saalfeld, unpublished data).

A complete population census was obtained annually in March by live-trapping deer and placing them in a holding pen. At this time, all deer were marked with numbered collars and weighed. In addition, adult does were X-rayed to determine stage of pregnancy and number of fetuses (Ozoga and Verme 1982). Age of fetuses was determined by comparing fetal radiograms with known-age fetal specimens (105 specimens ranging from 76 to 137 days old) determined by observed breeding dates (Ozoga and Verme 1985). Following this, birth dates were ascertained by using a 199-day gestation. Accuracy of this procedure was assessed by comparing predicted dates with known birth dates for 90 litters, and was found to be accurate within 3 days in 50% of litters, within 5 days in 66% of litters, and within 9 days in 93% of litters (Ozoga and Verme 1985). This variability fell within the natural variation expected in gestation times of well-nourished females (i.e., 196-213 days; Ozoga and Verme 1985). Pregnancy in fawns was also monitored at this time. Since fetuses within fawns would be too small to be detected on radiograms due to late conception dates, the presence of pregnancy in fawns was monitored through progesterone assay in peripheral plasma (Plotka et al. 1977).

Following the above procedures, deer were released back into a holding pen where they could be observed to confirm mother-fawn lineage from the previous year in some instances. Although most fawns were captured and tagged whenever possible within the enclosure to identify their mother, some were not captured until the March census. Therefore, observations at this time were used to either confirm or determine mother-fawn lineage as well as to document the dominance hierarchy among the deer. The dominance number assigned to each individual corresponded to the percentage of the herd that the individual dominated while inside the holding pen. Dominance was determined by observing interactions at feeding stations and recording the number of individuals dominated by a particular individual. All deer were released from the holding pen in late March or early April, and thereafter, observations were used to further elucidate behavioral patterns, social habits, birthing periods, rearing success, and sex of offspring. Fawns were captured and tagged whenever the opportunity arose and therefore most were already identified prior to the following March census. Those that were not tagged by the March census were identified and tagged for visual identification at this time (Ozoga and Verme 1982). All research was performed in a humane manner, followed ASM guidelines, and was approved by an institutional animal care and use committee.

In order to determine any possible role of birth date on offspring sex ratio we analyzed data similar to Smallwood and Smallwood (1998). We subdivided fetuses into 10-day intervals for the range of birth dates determined from fetal radiograms in this study (13 May–25 July). Since not all groups had adequate sample sizes (Figure 1), we pooled data of groups with samples sizes less than 10 litters. This resulted in the pooling of dates after 22 June. We then tested whether sex ratios differed among these groups using repeated measures analysis of variance repeated among years with a compound symmetric covariance structure and birthing group nested within year as our error term (PROC MIXED: SAS Institute 1999). In addition, to determine differences in physical condition by birth date between sexes, we tested if mass of fawns measured the following spring (March) differed among birthing groups (e.g., birth date) within each sex using the same repeated measures analysis of variance. To test the validity of maternal-condition-based hypotheses within this population, we investigated if any difference existed among maternal condition (i.e., body mass and dominance) or age for females that produced male or female fawns using repeated measures analysis of variance repeated among years with a compound symmetric covariance structure. Although we were unable to account for repeatedly sampling females, we tested whether sex ratios among the different birthing periods differed from equality using a Pearson chi-square.

Results

A total of 428 fawns from 251 litters was examined during the study from fetal radiograms: mean birth date was 4 June (n = 230; SE = 0.63 days), and mean number of fawns per doe was 1.85 (n = 230; SE = 0.04). The offspring sex ratio (50.4%) for the entire study did not differ from equality (χ^2 = 0.02; P = 0.880). We detected a difference ($F_{4,58}$ = 2.86; P = 0.031; Figure 2) in the proportion of males born among time periods, with a greater tendency of males being born in the second and fourth periods. We detected a greater proportion of males being born between 12 June and 21 June (70.4%) than between 13 May and 22 May (38.9%; t_{58} = –2.30; P = 0.025), 2 June and 11 June (46.5%; t_{58} = –2.78; P = 0.007), and 22 June and 25 July (38.9%; t_{58} = 2.11; P = 0.040). We also found a tendency for more males being born between 23 May and 1 June (58.0%) than between 2 June and 11 June, however only approaching significance (t_{58} = 1.78; P = 0.081). We found no differences among other time periods (P > 0.050). Additionally, we found that the second birthing period had a sex ratio different than equality (χ^2 = 3.93; P = 0.047).

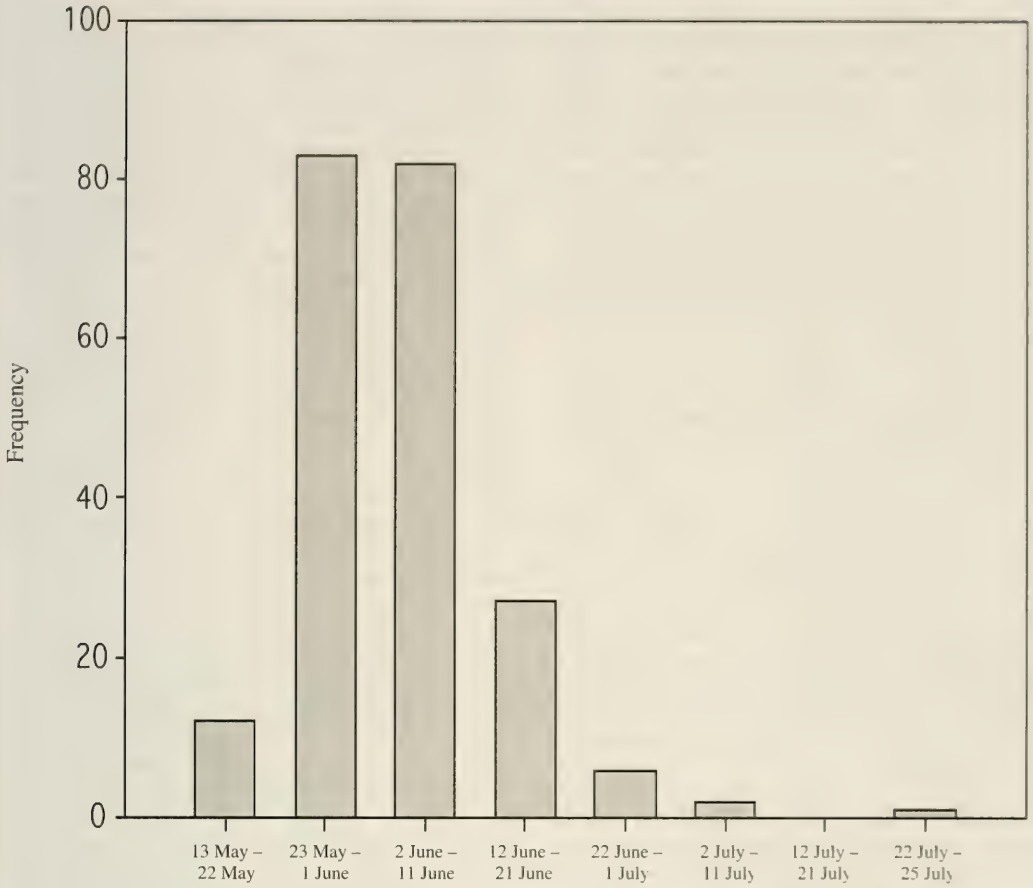

FIGURE 1. Frequency of White-tailed Deer litters in relationship to birth date from 1973 to 1984 (excluding 1974) at the Cusino deer research facility, Michigan, USA.

Body mass of fawns when approximately 9 months of age decreased as birth date became later for males ($F_{4,31} = 5.11$; $P = 0.003$), but not for females ($F_{4,30} = 1.94$; $P = 0.130$; Figure 3). We also did not detect any differences between body mass ($t_{57} = 1.60$; $P = 0.211$), dominance ($t_{56} = 0.00$; $P = 0.973$), or age ($t_{57} = 0.62$; $P = 0.434$) among mothers who produced either males or females.

Discussion

Our results support our hypothesis that offspring sex ratios differ based on birth date in White-tailed Deer. However, we found only moderate support for our hypothesis that more male offspring would be produced earlier in the birthing season as compared to females. Although we were unable to detect a significant difference in the sex ratios of the earliest birthing periods, we did find that more males tended to be born in the second birthing period resulting in a sex ratio different from parity. Although we found only a partial trend for this hypothesis, this trend has been demonstrated in other studies of White-tailed Deer, where it was found that more male offspring were likely to be conceived earlier in the birthing season (S. S. Ditchkoff, unpublished data; W. V. Underwood, unpublished data). In ungulates in a natural environment, individuals that are born earlier have more time to grow and access to more food than late-born conspecifics (Festa-Bianchet 1988; Singh et al. 1990; Festa-Bianchet et al. 1997; Côté and Festa-Bianchet 2001). While an earlier birth could be beneficial to both sexes, fitness gain would potentially be greater for males than females in a sexually dimorphic, polygynous species. Increases in body size and quality have been shown to strongly influence a male's initial reproductive success and lifetime fitness (Suttie 1983; Clutton-Brock et al. 1984; Kruuk et al. 1999; Festa-Bianchet et al. 2000). In addition, early births have also been shown to increase antler quality (Ozoga and Verme 1982; Schmidt et al. 2001; Gray et al. 2002), a trait which strongly affects

dominance and ultimately reproductive success in ungulates (Clutton-Brock and Albon 1980; Bowyer 1986). Also, postweaning male fawns have a greater dietary protein requirement than females (Ullrey et al. 1967). Therefore, being born earlier would be most beneficial for males, since earlier born individuals have better food availability than late born individuals. Female fitness, however, is not as strongly influenced by this initial disadvantage in body size. Jorgenson et al. (1993) found that condition in female Bighorn Sheep (*Ovis canadensis*) did not have a major effect on age at first reproduction. However, they did detect a minimum mass for young ewes to begin reproduction. Variation in mass above this minimum, however, did not effect age at first reproduction. Therefore, producing a particular sex at a certain time has an adaptive advantage for a mother which ultimately increases her lifetime fitness.

In White-tailed Deer, most births normally occur within a short time period (e.g., several weeks). For example, 61% of litters in our population were born during a 15 day period (28 May – 11 June). We expect that in species that have a much longer birthing period or multiple litters within a year, seasonal sex ratio biases would be more prominent. This is true in Virginia Opossums (*Didelphis virginiana*: Wright et al. 1995), Meadow Voles (*Microtus pennsylvanicus*: Dobson and Myers 1989), and Gray-tailed Voles (*Microtus canicaudus*: Bond et al. 2003), and this pattern has been termed the first-cohort advantage hypothesis (Wright et al. 1995). In Virginia Opossums, females had more male-biased first litters than second litters, possibly due to the increased reproductive fitness of males born earlier (Wright et al. 1995). Additionally, in Meadow Voles, more male-biased litters were born earlier in the season than later, corresponding to a similar pattern in litter size, which also declined as the season progressed (Dobson and Myers 1989). On the other hand, Bond et al. (2003), when examining Gray-tailed Voles, found female-biased litters rather than male-biased litters early in the season. They hypothesized that this trend was seen since females almost always reproduce their first year, while most late-born males delay first breeding until the following spring. Additionally, they speculated that winter survival could also influence Gray-tailed Vole sex ratios, where males born later had greater survival through winter than females born at the same time. However, this does not discount the importance of seasonal sex-ratio variation in a species like White-tailed Deer where births are highly synchronized. Our data demonstrate the relative importance of birth dates on female and male condition the following spring in White-tailed Deer. Males born in the earliest birthing period had 18.1% greater mass the following spring at 9 months of age than males born in the last birthing period. Early-born females also tended to have greater mass the following spring than late-born individuals, but the difference between the groups was less (9.7%). Since our study was conducted on a supplementally fed population, we suspect these differences to be less than in a natural population, where food would be limited during the winter months. Although these data do not measure future fitness, they provide strong support for the hypothesis that birth date differentially influences future fitness in males and females, as has been demonstrated in a number of avian species (Smallwood and Smallwood 1998; Pen et al. 1999; Cordero et al. 2001; Byholm et al. 2002; Griggio et al. 2002; Andersson et al. 2003; McIntosh et al. 2003). Despite this apparent trend, we did not detect a larger proportion of males born during the earliest time period. Although we are unsure of the specific reason for this, we suspect that early in the season, resource availability may be unpredictable. While giving birth early has advantages, it could also have disadvantages if food is unavailable or unpredictable at this time. Therefore, it may not be advantageous for females to invest in the more costly sex (i.e., males) if they may not be able to provide adequate nutrition for them. Low sample size during this time period (n = 12) could also have prevented us from detecting this trend.

Another interesting trend seen in our data was that more males were additionally born later in the season. This trend was also seen in American Kestrels, where more male-biased broods were born later in the season, although low sample size precluded statistical analysis (Smallwood and Smallwood 1998). Giving birth late in the season increases the likelihood of producing smaller, disadvantaged offspring of either sex. In Elk (*Cervus elaphus nelsoni*: Smith and Anderson 1998), Red Deer (*C. elaphus*: Clutton-Brock et al. 1987), and Moose (*Alces alces*: Keech et al. 2000) offspring of either sex that were late-born had decreased survival and reproduction. We propose that the best evolutionary strategy for a mother that conceives late may be to produce the dispersing sex. According to the local resource competition hypothesis (Clark 1978), a mother improves her own fitness, as well as that of previous and future offspring that reside within her home range, by producing the dispersing sex, which, by leaving, reduce competition for resources. Our data support this hypothesis, since both males and females born late in the birthing season had low mass the following spring compared to offspring born early. Despite this trend, we were unable to detect a greater proportion of males produced in the last time period, possibly due to the low sample size (9 litters).

Differing sex ratios according to birth date is an overlooked but perhaps very important tactic for increasing lifetime fitness of White-tailed Deer and other polygynous mammals. Although this is not the first documented evidence of seasonal variation in sex ratios in ungulates (Clutton-Brock et al. 1982; Kohlmann 1999) or large sexually dimorphic mammals (Coulson and Hickling 1961; Stirling 1971), we believe our data

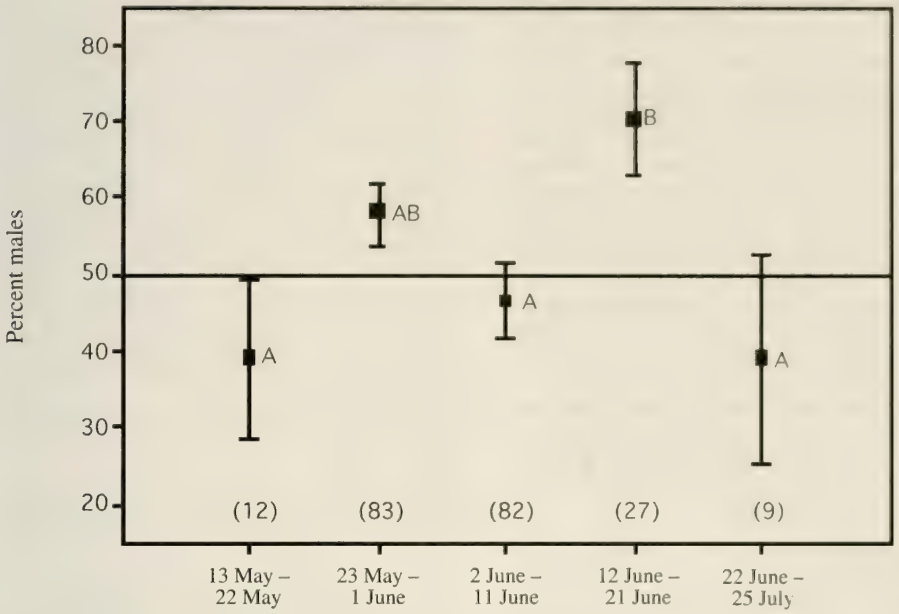

FIGURE 2. Litter sex ratio of White-tailed Deer offspring in relationship to birth date from 1973 to 1984 (excluding 1974) at the Cusino deer research facility, Michigan, USA. Means with the same letters are not different ($P > 0.05$). Numbers correspond to sample sizes of litters in each time period.

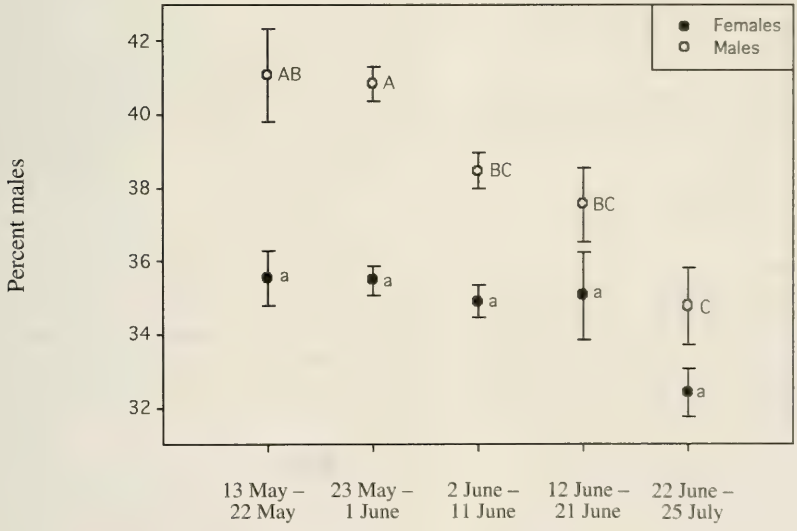

FIGURE 3. Mass of 9-month old male and female White-tailed Deer fawns born in relationship to birth date from 1973 to 1984 (excluding 1974) at the Cusino deer research facility, Michigan, USA. Means with the same letters within an age class are not different ($P > 0.05$).

provides a better explanation for this phenomenon than has previously been proposed. Although there are numerous factors that influence sex ratios and timing of birth, it appears that timing of birth was the main cause of variation in sex ratios in the population we studied. Although our data were collected from a captive herd of White-tailed Deer, we assume that they are representative of a natural population, and since food was provided year round and a stable population was ensured, we expect some of the trends we have noted to be more dramatic in a natural population. This seasonal variation would be most beneficial in species where reproductive success is correlated with initial body mass and therefore birth date of a particular sex. This initial advantage for one sex may be based on a variety of life history traits that differentially affect one sex more than the other such as in sexually dimorphic, polygynous species that exhibit sex-biased competition for mates or territories.

Acknowledgments

We thank all of the individuals that assisted with data collection at the Cusino Enclosure during the time the research was conducted. This research was supported by the Center for Forest Sustainability and the School of Forestry and Wildlife Sciences at Auburn University, the Alabama Cooperative Fish and Wildlife Research Unit, and the Michigan Department of Natural Resources.

Observation of Foliage-roosting in the Little Brown Bat, *Myotis lucifugus*

Christina M. Davy[1] and Erin E. Fraser[2]

[1] Department of Ecology and Evolutionary Biology, University of Toronto, Canada
[2] Department of Biology, University of Western Ontario, Canada

Davy, Christina M., and Erin E. Fraser, 2007. Observations of folige-roosting in the Little Brown Bat, *Mytotis lucifugus*. Canadian Field-Naturalist 121(4): 420.

First report of foliage-roosting behaviour in a Little Brown Bat (*Myotis lucifus).* The observation is discussed in relation to similar behaviour in other bat species.

Key Words: Little Brown Bat, *Myotis lucifugus,* foliage roosting, Ontario.

We report the occurrence of foliage-roosting behaviour by a Little Brown Bat, *Myotis lucifugus,* which is generally considered a cavity-roosting species (e.g., Barbour and Davis 1969; Fenton and Barclay 1980; Barclay 1980). At 11:00 hrs on 18 July, 2004, in Algonquin Provincial Park (Ontario, Canada) we observed a single *M. lucifugus* hanging by one foot from a relatively exposed maple leaf (*Acer saccharum*) at a height of about 5 m. The bat was torpid, and would have been well camouflaged had it not been roosting directly opposite a small deck. When captured and handled, it woke from its torpid state within 45 s. and behaved normally. The bat had a number of ectoparasites (bat bugs) on it. However, its ectoparasite load was not higher than the loads observed on several other bats captured in the area, so we have no reason to assume the bat was in poor health.

To our knowledge this is the first time that day-roosting in foliage has been reported for *M. lucifugus,* or any North American *Myotis,* although it is known from other species in the genus (e.g., the Taiwanese endemic *M. formosus*; Y. Ho, personal communication). Other foliage-roosting species in Ontario, such as the larger and more brightly coloured *Lasiurus* species are notoriously difficult to spot in mature forests (Fenton 1998; B. Hickey personal communication), so such behaviour could be easily missed. The Eastern Pipistrelle (*Pipistrellus subflavus)* was previously believed to be an obligate cavity rooster until it was recently found frequently roosting in foliage (Veilleux et al. 2003).

The individual that we observed was less than 100 m from an old building that contained a maternity colony of *M. lucifugus* (>50 individuals), While we cannot discount the possibility that it was a sick or excluded member of the colony, we observed no indications of acute illness. We suggest that our observation represents further evidence that many bat species are capable of substantial behavioural flexibility.

Acknowledgements

Our observation occurred during a survey of the bats of Algonquin Provincial Park. We acknowledge the generous support of M. Brock Fenton, the Ontario Ministry of Natural Resources, and the Friends of Algonquin Park, which made the survey possible.

Cheney, Michael, and Kendrick L. Marr. 2007. Cowbane, *Oxypolis occidentalis*, a new native plant species for the Queen Charlotte Islands, British Columbia. Canadian Field-Naturalist 121(4): 421-422.

We report the recent discovery of *Oxypolis occidentalis*, a species that is new to both British Columbia and Canada, disjunct on the Queen Charlotte Islands.

Key Words: Native vascular plants, new records, *Oxypolis occidentalis*, Cowbane, Apiceae, Queen Charlotte Islands, British Columbia, Canada.

The Queen Charlotte Islands, a group of islands lying off the north coast of British Columbia, continue to yield new and interesting floristic finds. In the summer of 2001, Michael Cheney found a small colony of an unknown Apiaceae growing in and around a series of seepage pools in an old-growth forest margin at approximately 300 m elevation on south-central Graham Island in the Queen Charlotte Islands. A specimen (Cheney *s.n.*; V190944) was sent to the Royal British Columbia Museum (V) for identification, as it did not match any Apiaceae from British Columbia. Here it was identified as *Oxypolis occidentalis* J. Coulter & Rose, using the *Flora of California* (Constance 1993). A specimen sent to the Rocky Mountain Herbarium (RM) (NIS# 2003-133 [DAO]) was also identified as *O. occidentalis* by Ronald Hartman (RM). Specimens were also deposited in the Ministry of Forests herbarium at Smithers (S). Verification of the identification of *O. occidentalis* was based upon the original description (Coulter and Rose 1900) as well as comparison with herbarium specimens (OSU141785, OSU177111, UC177437) from Oregon and California. The Queen Charlotte Islands specimen matches these specimens in the following characters: seed morphology, little variation in ray length, and the size, shape and serration of the leaflets.

Oxypolis occidentalis is new to Canada and belongs to a solely North American genus of six species, found in eastern and western North America and the Caribbean (Constance 1993). In Canada, one other species in this genus has been collected, *O. rigidior* (L.) C. & R., a species of bogs and wet meadows. This species was collected in southern Ontario in bogs, wet woods and swamps, only from 1886 to 1901, and possibly is now extinct (Scoggan 1979).

The closest populations of *O. occidentalis* to the Queen Charlotte Islands populations are approximately 1400 km distant. The northernmost is from eastern Lane County (Oregon Vascular Plant Database Record: ORE103195) in westcentral Oregon as well as Jackson and Lake counties of southern Oregon (Peck 1961). The distribution of collections in California is centred in transmontane California, particularly the high Sierra Nevada and the foothills regions of Fresno, Mariposa, Tulare, and Tuolumne counties from 1200-2600 m in bogs, wet meadows, streamsides and coniferous forests (Constance 1993).

In the summers of 2002 and 2003, 10 other widely-dispersed sites were discovered, revealing that *O. occidentalis* ranges extensively on the south-eastern flank of the Skidegate Plateau in suitable sites from 250-370 m elevation. It is quite possible that it is also found throughout the Skidegate Plateau and in other suitable habitats in the Queen Charlotte archipelago. Only one lowland site has been discovered, at approximately 10 m elevation, 3 km north of Port Clements. Specimens of *O. occidentalis* at this site are confined to a shady area approximately 100 m^2, though this small area is densely populated with *O. occidentalis*.

At the higher elevation sites on the Queen Charlotte Islands, *O. occidentalis* is very frequently associated with *Veratrum viride*, *Senecio triangularis* and *Carex stylosa*. The lowland population is associated with *Angelica genuflexa, Carex cusickii, Lysichiton americanus, Menyanthes trifoliata,* and *Oenanthe sarmentosa*. The known distribution of the populations on the Queen Charlotte Islands, along with its narrow habitat preferences and its presence in forests that have not been logged or otherwise disturbed by humans, suggest that it is not a recent introduction. Whether *O. occidentalis* is also found in some of the many suitable habitats on Moresby Island remains, for the moment, an intriguing question and one that may shed some light on its status as a native species of the Queen Charlotte Islands.

The existence of a disjunct Queen Charlotte Island population of *O. occidentalis* raises biogeographical questions. Queen Charlotte Islands specimens of *O. occidentalis* are being examined using molecular techniques at the University of Illinois as part of a systematic and phylogenetic treatment of the genus. The results of this investigation should contribute further to an understanding of the biogeographical relationships between the Queen Charlotte Islands populations and those further south.

Todd Powell, Thomas S. Jung, and Karen J. Clyde. 2007. Apparent predation of an American Water Shrew, *Sorex palustris*, by an American Marten, *Martes americana*. Canadian Field-Naturalist 121(4): 422-423.

Little is known of the natural history of American Water Shrews, *Sorex palustris*, including their predators. We document an apparent case of predation of an American Water Shrew by an American Marten, *Martes americana*, in the boreal forest of southeastern Yukon.

Key Words: American Marten, *Martes americana*, American Water Shrew, *Sorex palustris*.

Little is known of the natural history of the American Water Shrew (*Sorex palustris*). For example, incidents of predation are rarely noted, despite the fact that the relatively large size of its skull should be easy to identify in the stomachs, scats, or pellets of predators. The American Water Shrew is semi-aquatic and the vast majority of records are from within several metres of a waterbody (Benenski and Stinson 1987, Nagorsen 1996). As such, most non-volant predators of American Water Shrews are aquatic or semi-aquatic, including large frogs, snakes, and fish (Benenski and Stinson 1987; Nagorsen 1996). The American Mink (*Neovison vison*) is the only reported mammalian predator of the American Water Shrew (Benenski and Stinson 1987), and it also is semi-aquatic. We are not aware of any observations of terrestrial mammals preying upon American Water Shrews. Here, we provide an observation of apparent predation of an American Water Shrew by a terrestrial predator, the American Marten (*Martes americana*).

Our observation was made during a live-trapping study of American Marten near Watson Lake, Yukon (60.2°N, 128.7°W). On 13 July 2006, we captured an American Marten and found a dead shrew at the entrance of the trap. The shrew was identified as an American Water Shrew using the key provided by Nagorsen (1996). The trap site was in upland boreal forest, about 350 m from the nearest waterbody.

We surmise that the Marten was carrying the Water Shrew and dropped it prior to entering the trap. Alternatively, the Water Shrew may have been feeding on the bait in the trap, where the Marten found it and killed it. The latter hypothesis is not likely, however, because the Water Shrew was found outside the trap; for this hypothesis to be more plausible then the Water Shrew should have been found inside the trap. Therefore, we believe that the Marten killed the Water Shrew before it had entered the trap. It is not known, however, if the Marten would have consumed the Water Shrew.

Several studies of food habits of American Marten have reported that shrews are among the least preferred prey item of American Marten (e.g., Cowan and Mackay 1950; Quick 1955; Douglass et al. 1983; Slough et al. 1989; Thompson and Colgan 1990; Nagorsen et al. 1991; Simon et al. 1999). All shrews found in the stomach contents or scats of Marten have been terrestrial species (e.g. *S. cinereus*, *S. hoyi*, *S. monticolus*). Our observation adds the American Marten as a likely predator of the semi-aquatic American Water Shrew.

We do not know where the Marten killed the Water Shrew, but we find it interesting that the Marten may have killed the shrew while it was away from a waterbody. On 8 July 2006, we found a dead American Water Shrew about 400 m from a small pond near Whitehorse, Yukon (60.5°N, 135.1°W) that was killed by a tethered sled dog. In another instance, on 20 September 2005, we trapped an American Water Shrew in a pitfall trap in a clearcut near Watson Lake, Yukon, that was 1.1 km from water. Other observations of American Water Shrews away from water have been noted (e.g., Kinsella 1967; Wrigley et al. 1979). Taken together, these observations suggest that American Water Shrews may make overland movements, and

that they may be susceptible to mortality during these movements, including predation.

Giant Pacific Octopus, *Enteroctopus dofleini*, Attacks on Divers

ROLAND C. ANDERSON[1], RONALD SHIMEK[2], JAMES A. COSGROVE[3], and STEVE BERTHINIER[4]

Anderson, Roland C., Ronald Shimek, James A. Cosgrove, and Steve Berthinier. 2007. Giant Pacific Octopus, *Enteroctopus dofleini*, attacks on divers. Canadian Field-Naturalist 121(4): 423-425.

Documentation is given of four instances of attacks on scuba divers by the giant Pacific octopus.

Key Words: Giant Pacific Octopus, *Enteroctopus dofleini*, Mollusca, Cephalopoda, attacks, Washington, British Columbia.

In the cold waters around the North Pacific live some truly giant animals. Among them, individuals of one octopus species, *Enteroctopus dofleini* (Wülker, 1910) have been documented to weigh over 68 kilograms (150 pounds) (Cosgrove 1987), making it the world's largest octopus (Norman 2002). Although octopuses (the now preferred plural) have been portrayed as monsters in fiction, folklore, and movies such as *It Came from Beneath the Sea*, octopuses are, as a whole, not monsters, but interesting and intelligent creatures (Mather and Anderson 1993, 1998*). Although predatory, they are generally shy and retiring animals that would rather retreat to a den than have any contact with humans (Hartwick 1983; Hanlon and Messenger 1996). We have emphasized "as a whole" and "generally" because octopuses, particularly the larger, more experienced ones, are individuals (Anderson and Wood 2001). As should be expected with individuals, they may show decided differences in how they react to any given situation. Sometimes divers will encounter a large octopus that is bold and aggressive rather than shy. The motivations for aggression in normally docile animals are unknown. It is possible that these animals may want to see if a diver has food or frankly, they may well be considering that the diver is food. Whatever the cause, we here relate four instances of octopus attacks on divers.

Fishy Business

A diving crew from the Seattle Aquarium was collecting animals near Slant Rock on the outer coast of Washington State. With rocky cliffs plunging dramatically into the cold Pacific, this is one of the more picturesque areas in a beautiful state. Upwelling at the entrance to the Strait of Juan de Fuca keeps water clear and as cold as 4.4°C (40°F) in the summer! Six meter

(twenty foot) swells are common and the vigorous wave action on the rocks keeps the water well-oxygenated making it prime octopus habitat. While common, mature male octopuses in this area are generally small, weighing 14 kg (30 pounds) or less; in nearby Puget Sound mature male octopuses are commonly 27 kg (60 pounds) or heavier.

The team was collecting adult rockfish with a barrier net. Two divers direct the fish into the net, where they are captured. A third diver bags the fish caught in the net. On this occasion the bagger noticed that a small octopus, having an arm span of about 2.4 meters (8 feet) and an estimated weight of about 6.8 kg (15 pounds), had crawled onto the net and had "flared" across it. When the two other divers returned, the octopus reached out to each and held onto them, one at a time. It actually pulled off one diver's dry suit glove, causing him great aggravation as the cold water leaked up his sleeve. The divers gently pushed the octopus away knowing, from past experience, that this should be enough to scare it off. They then picked up their gear and moved to a different nearby area. While floating in the water 1.5 or 1.8 meters (5 or 6 feet) off the bottom, they were surprised to see the octopus crawling across the bottom toward them. It attacked them again, doing a flaring webover pounce on each of them. When one diver had wrestled it off, it moved to another diver and repeated the behavior. The divers could not get rid of the animal. This so broke up their concentration they decided to surface to the support boat overhead, laughing about the horrible octopus attack!

Now, a 6.8 kg (15 pound) octopus is by no means a monster. The attack these veteran divers experienced was no worse than a puppy worrying a shoelace. But as a puppy might chew through an electrical cord, so might a small octopus do damage in an encounter with a diver. A giant Pacific octopus has a formidable beak that could tear a diver's suit or flesh (Snow 1970; Anderson 1999). The octopus can also inject a venomous saliva into a bite (all octopuses are venomous) (Hanlon and Messenger 1996). However, if a big octopus were to attack a novice diver, the outcome could be different. Instead of surfacing laughing, the diver might not surface at all. The following anecdotes of octopus attacks are more serious and the outcome could have easily been tragedy but for the experience and professionalism of the divers plus some good luck.

Kick Me, Will You?

The second incident happened at Small Pox Bay on the San Juan Island in Northern Puget Sound. Two divers were swimming out into the bay from the shore. One diver was about 3 meters (10 feet) ahead of and above his partner. He looked back at his buddy and saw him kick a big rock. Immediately the "rock" changed color to white then dark red! It was a large octopus, at least 3 meters (10 feet) across its arms. The animal extended one arm over the unaware diver's fins and ankle, immobilizing him. His forward velocity ceased and, severely startled, he attempted to rise up in the water. He was securely held by the octopus clinging to him and onto the rocks beneath it. The diver grabbed his dive knife and slapped at the octopus' arm. The mollusk responded by wrapping another arm around the diver's legs. He again attempted to ascend and did rise a bit, but the octopus was now moving up toward him by shortening the arms holding the diver and lengthening the arms anchored to the rock beneath it. The diver was working hard enough that a steady stream of air came out his regulator; no discrete breaths were noticeable. The diver approached a nearby cliff and picked up a boulder. The diver attempted to drop it on the large mollusk but just as he did so, the octopus let go, jetted to the bottom and swam off rapidly. During the approximately two minutes of the encounter, the victim had exerted enough effort in trying to break free of the octopus that he had just 20% of his breathing gas (600 psi) left in his tank. His buddy's tank had 67% (2000 psi) remaining. This attack appeared to be the result of simple aggravation at being kicked.

I Don't Like Your Looks

At the Keystone Jetty on Whidbey Island, Washington, a diver was signaled by his buddies to come see a large octopus sitting in front of its den. As he swam over, the octopus turned and faced this diver for a moment then it rapidly swam toward him. The diver used his camera to fend it off. This worked for a while. The animal then pulled on his camera, tugging on the strobes, strobe arms and whole assembly before moving to the diver himself. At first the diver thought: "This is cool, it's going to check me out," then he felt it pulling his mask off. Suddenly it was decidedly "uncool." He grabbed what he could on the bottom and pushed the animal off, holding tight to his mask and biting tightly to hold on to his regulator. The octopus finally let go and retreated back to its den after the diver's buddies shone an ultra-bright canister light at it.

"Come Into My Parlor," Said the Spider to the Fly...

The next attack occurred in Saanich Inlet on Vancouver Island, British Columbia. The diver was a scientist working for a crew filming octopuses. The scientist was very experienced at handling and being around octopuses. He had enticed an octopus to leave its den and the film crew went off with it. As the diver, now alone, gathered his equipment, a second octopus came out of an unseen den. After looking at the diver for a moment, the octopus crawled quickly to the diver's chest and, while remaining firmly anchored to the rocks below with several arms, it seized his upper arms, chest and head. The octopus got three suckers onto the

diver's bare forehead and wouldn't let go. The pressure from the suckers created bruises that lasted for about a week. During the roughly three-minute struggle the diver fought to keep his regulator in his mouth by biting down hard on the mouthpiece and using both hands to cover it. The diver eventually outlasted the octopus but in the struggle lost his mask, had his hood pulled partially off and had his dry suit flooded. As might be expected, he also used up a significant amount of breathing gas. The octopus finally gave up on this test of strength and let go. The diver felt that, had he lost his regulator or had he been low on air, he would have undoubtedly died. The octopus was just too strong for him to do anything but hang onto his regulator and brace himself from being pulled into the den.

Some Thoughts

Most large octopuses are "pussycats." Usually, the larger they are, the more placid and relaxed they are. But as these experiences indicate, there are exceptions. At certain stages in their lives, octopuses are lean, mean, eating machines. They can put on 2% of their body weight per day (Hartwick et al. 1981; Cosgrove 1987) so they are constantly looking for food. "Checking out a diver" with chemotactic suckers may simply be seeing if he or she is edible. As far as we know, the octopuses will let go when they find they cannot subdue a diver, or the diver is not edible, but the diver needs to remain calm and keep a tight grip on his or her regulator. So far, we can document no case of a Giant Pacific Octopus attack that has resulted in a diver fatality, but there have been diver deaths where no cause is found to explain the tragedy. Perhaps octopuses were involved in these deaths but even it they were not it is wise for all divers to be respectful of the potential danger of these powerful animals.

MacKinnon, Colin M., Andrew C. Kennedy, and Donald W. Colpitts. 2007. Details of eastern Coyote *Canis latrans* predation on Great Black-backed Gull *Larus marinus* eggs on Boot Island National Wildlife Area, Nova Scotia. Canadian Field-Naturalist 121(4): 426-428.

We detail field observations of Eastern Coyote eating Great Black-backed Gull eggs for the first time in the literature. Photographic evidence of the remaining egg shells allowed us to identify the Coyote as the predator.

Key Words: Eastern Coyote, *Canis latrans*, Great Black-backed Gull, *Larus marinus*, seabird, egg predation, Boot Island National Wildlife Area, Nova Scotia, Canada.

Parker (1995) discussed in detail the recent colonization of eastern Canada by the Eastern Coyote *Canis latrans*. The coyote arrived in New Brunswick from Maine around 1970 and this expansion continued eastward; it was found in mainland Nova Scotia by 1980 and on Prince Edward Island by 1983. Studies of coyotes in eastern Canada have reported that White-tailed Deer (*Odocoileus viginianus*) and Snowshoe Hare (*Lepus americanus*) are important prey species (Moore and Miller 1986; Parker 1986; Morton 1988; Patterson and Messier 2001). However, throughout their range Coyotes are opportunistic and have a diversified diet (Berg and Chesness 1978; Parker 1995). In recent years, tracks and scats of coyotes have been found on a number of off-shore islands in eastern Canada including areas important to nesting seabirds (MacKinnon et. al. 2006*). However, actual detailed descriptive information on coyote depredation on seabirds (adults, eggs, or chicks) is generally lacking in the literature.

Colonial nesting birds typically prefer remote islands to escape terrestrial predators and mammalian disturbance. One such colonial seabird colony is located on Boot Island, Kings County, Nova Scotia (45°08'N, 64°16'W). Boot Island is a 144 ha protected area (Boot Island National Wildlife Area) consisting of 135 ha of saltmarsh and two upland islands adjacent to the marsh. The smaller island (0.5 ha), referred to as "Cyril's Island", is surrounded by saltmarsh and is located along the northwest border of the NWA. The main island, Boot Island proper (8.5 ha), is bordered by saltmarsh to the southwest and 5 m cliffs to the northeast. Boot Island and Cyril's Island are predominantly long-abandoned farm land (6.5 ha) dominated by two species of wild mustard – Wild Radish, *Raphanus raphansitrum,* and Hairy-pod Hedge Mustard, *Sisymbrium officinale*. The highest ground is dominated by a small area (2.0 ha) of dead and dying White Spruce, *Picea glauca,* with an understory of predominantly Red Elderberry, *Sambucus racemosa,* (Newell et. al. 2006). The western side of Boot Island is separated from the nearest mainland by a narrow creek (340 m across water at low tide).

In 2006, the island supported the following colonial-nesting birds: Great Black-backed Gull, *Larus marinus*; Double-crested Cormorant, *Phalacrocorax auritus*; Great Blue Heron, *Ardea herodias*; and Herring Gull, *Larus argentatus*, with 943, 151, 52 and 22 breeding pairs, respectively (MacKinnon et. al. 2006*). The heron and cormorant nests were in trees and restricted to the forested area while the Great Black-backed Gull nests were scattered throughout the old field habitat. Herring Gull nests were relegated to a few small pockets within the much larger Great Black-backed Gull colony.

Evidence of Coyote activity (tracks and scats) had been recorded on earlier visits to Boot Island (personal observations). On 10 May 2004, the authors directly observed a Coyote in the act of egg depredation. We arrived on the island near high tide, around 06:50 AST, and began a nest survey of the gull colony. By 12:50, the survey was completed and C. M. M. and D. W. C. were at the extreme northwestern edge of the main island. At that time we observed a Coyote walking towards us in an easterly direction, across the saltmarsh. Its coat was wet (the day was sunny and clear, 14°C) suggesting the animal had just swum across the narrow creek between Boot Island and the mainland. When the coyote was first observed, D. W. C. was sitting on the shore behind a large piece of driftwood, and C. M. M. was standing, in full view, in the saltmarsh just east of Cyril's Island, about 100 m from D. W. C. Observations of Coyote behaviour were made at ~ 50 m using 10 × 40 Leitz Trinovid binoculars. The Coyote proceeded east, passing within 25 m of the senior author, before changing direction towards the gull colony on the main island. Upon reaching the high water mark on the main island (site of the Great Black-backed Gull colony), the Coyote slowed and purposefully hunted the upper edge of the seaweed

Figure 1. Dimple marks made by Coyote's teeth (probably the premolars) when carrying a Great Black-backed Gull egg, Boot Island National Wildlife Area, Nova Scotia, 2004. (A. Kennedy photo)

Figure 2. Lateral 'slice' made by the canine teeth of a Coyote to open a Great Black-backed Gull egg, Boot Island National Wildlife Area, Nova Scotia, 2004. (A. Kennedy photo)

"wrack" line apparently searching for gull nests. It immediately encountered a Great Black-backed Gull nest, picked up an egg with its mouth and carried it a few meters carefully cradled in its jaws, before slicing it open and eating the contents. Upon seizing the egg, the Coyote left several small tooth impressions (indentations), next to each other, on one side of the egg (Figure 1). The Coyote opened the egg by positioning it in its jaws allowing one side of its canine teeth to make a "slice" across the thickest portion (Figure 2). As a result of this lateral cut through the egg, the shell fragments along the edge of the slice appeared oriented in the direction of the cut as opposed to facing uniformly inward as would be expected from a puncture. The Coyote then dropped the damaged egg on the ground, spilling the contents (mostly yolk) into the grass where it was quickly lapped up. The Coyote consumed a number of eggs (> 5) from different nests in the same manner. It then continued eastward, away from our point of observation, presumably predating more nests and paying little attention to the observers or the hundreds of very vocal Great Black-backed Gulls. The Coyote was of average size (~15 kg) and appeared to be healthy and in good physical shape.

The process of how the Coyote opened the gull eggs prior to consuming the contents, as well as the telltale marks left on the egg remnants, was not expected. Had we encountered similar broken gull eggs, without knowing that they had been depredated by a Coyote, we probably would have attributed this predation to American Crow, *Corvus brachyrhynchos*, or Common Raven, *Corvus corax*. are frequently observed foraging in seabird colonies and depredated eggs with puncture marks are routinely attributed to these birds by researchers. Causes of predation are particularly important if one is trying to determine survival rates of eggs of various seabird species.

The gull colony on Boot Island National Wildlife Area has been declining in recent years with a near linear decrease in Herring Gull nests from 727 in 1986 to only 22 in 2006 (MacKinnon et al. 2006*). Great Black-backed Gulls have also experienced a less drastic, although similar, decline. It is as yet unclear to what extent Coyote predation may have on the decline in gull numbers being observed on Boot Island. This note provides recognizable characteristics on depredated gull eggs which may help identify egg loss from Coyotes versus other predators.

Red-breasted Nuthatch, *Sitta canadensis,* Dies Stuck in Resin at Entrance to a Nest-box

CLIVE F. STRAUSS

975 Ridgeway Street, Victoria, British Columbia V8X 3C2 Canada; e-mail: cstrauss@islandnet.com

Strauss, Clive F. 2007. Red-breasted Nuthatch, *Sitta canadensis*, dies stuck in resin at entrance to a nest-box. Canadian Field-Naturalist 121(4): 428-429.

I document a female Red-breasted Nuthatch (*Sitta canadensis*) found dead and stuck to resin in the opening of a nest-box in an urban setting. This is the second reported occurrence of such mortality and the first involving a nest-box. This species applies resin to its nest openings to deter predators and reduce competition or parasitism from other species. Red-breasted Nuthatches infrequently utilize nest-boxes. At necropsy this female nuthatch was found to be carrying a fully-formed egg with shell and this increase in abdominal girth may have contributed to her demise.

Key Words: Red-breasted Nuthatch, *Sitta canadensis*, mortality, resin, nest-box, British Columbia.

On 12 April 2007 I found a dead female Red-breasted Nuthatch (*Sitta canadensis*) stuck in the opening of a nest-box about 5 m above the ground under the west-facing eaves of a city residence in Victoria, British Columbia (48°20.0'N, 123°22.0'W). The entrance of the nest-box was covered by a hard transparent acrylic plate, measuring 6.7 × 6.0 cm with an oval entrance hole of diameter 3.4 × 3.0 cm, designed to exclude House Sparrows (*Passer domesticus*). Earlier a Chestnut-backed Chickadee (*Poecile rufescens*) was seen building a nest in this nest-box, and it was often interrupted by a Red-breasted Nuthatch pecking at the opening and calling persistently.

Extraction of the dead nuthatch resulted in numerous chest and abdominal feathers remaining stuck in the entrance hole of the nest-box (Figure 1). It was observed that the acrylic plate was irregularly covered in sticky resin that had an odor suggestive of a coniferous tree. The interior of the box revealed a newly built chickadee nest made out of moss but devoid of eggs. Subsequent to the removal of the dead bird, a pair of Red-breasted Nuthatches was seen "excavating" this nest-box by removing moss. In previous years, Violet-green Swallows (*Tachycineta thalassina*) successfully raised broods in this nest-box. The acrylic plate was added only after House Sparrows killed several swallow nestlings.

Several observers in British Columbia (Campbell et al. 1997) and elsewhere (Bent 1948; Ghalambor and Martin 1999) have reported Red-breasted Nuthatches daubing resin around the entrance of their nest holes, it is thought, to protect the nest against competition from other cavity-nesting birds or mice, as well as against predation by other species or insect parasitism. In most cases this seems to pose little risk to the nuthatch itself but seems to deter competitors (Ghalambor and Martin 1999). Daubing nest entrances and cavities with mud or insects is known for other *Sitta* species (Pasquet 1998).

A literature search of the nesting behaviour of the Red-breasted Nuthatch revealed only one previous report of death at the entrance of nest hole: Kilham (1972) reported a dead female Red-breasted Nuthatch found stuck to the resin in the entrance of a tree cavity. Red-breasted Nuthatches infrequently utilize nest-boxes. Dunn et al. (1975) described two nest-boxes utilized out of 100 designed for Black-capped Chickadees (*Poecile atricapillus*) in a pine plantation on the north shore of Lake Erie. Those nest-box entrances were also heavily daubed with pine (*Pinus* sp.) resin. Nest-box sites were utilized in only two out of 143 nests in British Columbia reported by Campbell et al. (1997). The Cornell Laboratory of Ornithology recommends a circular nest-box entrance hole with a diameter of 3.2 cm for Red-breasted Nuthatches (Cornell Lab of Ornithology, The Birdhouse Network. Habitat Requirements Available: www.birds.cornell.edu/birdhouse/bios/nestrequire/habitat. [Accessed 1 May 2007]). The hole in the cover plate in this instance measured 3.4 × 3.0 cm.

The dead Red-breasted Nuthatch was found to contain a complete egg with shell as well as three develop-

FIGURE 1. Photograph of the acrylic nest-hole cover (removed from the nest-box) with an oval entrance hole of diameter 3.4 × 3.0 cm, showing the Red-breasted Nuthatch feathers stuck to sticky resin on the lower half.

ing ova in the ovary. It is possible that the increased abdominal girth of this gravid female nuthatch contributed to her getting trapped and subsequent demise

Acknowledgments

My thanks to A. E. Burger of the Department of Biology, University of Victoria, for performing the necropsy of the dead bird and for his helpful assistance in the preparation of the manuscript.

Attempt to Cross-Foster Gray Wolf, *Canis lupus*, Pups into Another Wolf Pack

RONALD N. SCHULTZ[1], ADRIAN P. WYDEVEN[2], LINDA S. WINN[1], and SHERI A. BULLER[1]

[1]Wisconsin Department of Natural Resources, 8770 Highway J, Woodruff, Wisconsin 54568 USA
[2]Wisconsin Department of Natural Resources, 875 South 4th Avenue, Park Falls, Wisconsin 54552 USA

Schultz, Ronald N., Adrian P. Wydeven, Linda S. Winn, and Sheri A. Buller. 2007. Attempt to cross-foster Gray Wolf, *Canis lupus*, pups into another wolf pack. Canadian Field-Naturalist 121(4): 430-432.

We attempted to cross-foster four 18-19 week-old Gray Wolf (*Canis lupus*) pups into another Wolf pack 182 km from their natal pack territory. The pup introduction was the result of depredation control on a farm in northwestern Wisconsin. Three pups died within 14 days of release. A fourth pup survived along the edge of the new pack territory over winter, dispersed in the spring, joined or formed a new pack and was captured on a depredation complaint four years later.

Key Words: Gray Wolf, *Canis lupus*, introduce, depredation, natal pack, Wisconsin.

Depredation control programs on Gray Wolves, (*Canis lupus*) may create concern about how to humanely deal with wolf pups captured at depredation sites. Such problems can be especially acute when lethal controls are not allowed.

It has been demonstrated that Black Bear (*Ursus americanus*) cubs have been successfully introduced to other female bears (Carney 1985). Cross-fostering of week-old captive Coyote (*Canis latrans*) pups was highly successful (Kitchen and Knowlton 2006). Cross-fostering has been successful in captive Red Wolves (*Canis rufus*) with all fostered wolves surviving to weaning (Waddell et al. 2002*), and has been successful for captive Gray Wolves (*Canis lupus*) (Goodman 1990). Two captive-born Red Wolf pups were fostered into a wild wolf den containing two pups of identical age in 2002 (U. S. Fish and Wildlife Service 2004 Fostered red wolf recaptured and released. Red Wolf News 5: 2, US Fish and Wildlife Service, Manteo, North Carolina, Unpublished report). Two 6-month-old pups that were given standard soft releases in separate translocation incidents remained cohesive with adult pack members after release and survived (Bradley et al. 2005). In Wisconsin a wolf pup was successfully reintroduced back into its natal pack after 53 days in captivity (Schultz et al. 1999).

However, not all cross-fostering pup translocation attempts have been successful. An attempt was made to cross-foster six 3 to 4-week-old Mexican wild wolf pups (*Canis lupus baileyi*) to a surrogate adult pair at the Sevilleta National Wildlife Refuge Mexican Wolf Management Facility that had two pups, but they were rejected and killed by the adult male (Mexican Blue Range Reintroduction Project Monthly Update 1 – 31 May 2006. Unpublished report). Two hard release translocation events, including three 5-month-old pups in northwestern Montana resulted in abandonment by adult members after release, and the pups died soon thereafter (Bradley et al. 2005).

To our knowledge there have never been any attempts made to cross-foster 18 to 19-week-old weaned free ranging wild Gray Wolf pups into another wild wolf pack. We describe an experimental cross-fostering of wild post-weaning Gray Wolf pups at an age before they began accompanying adults on hunts (Mech 1970) into another pack territory in Wisconsin during a time when translocations were used to deal with problem wolves.

Methods

Four 13 to 14-week-old Gray Wolf pups, two females (F390, F393) and two males (M391, M392) were captured on a farm in northwest Wisconsin where cattle were being killed by wolves. Wolf M392 was captured on 25 July, M391 on 27 July, F390 on 30 July, and F393 on 31 July 2001. A lactating adult female, F367 was previously caught on this farm on 26 May 2001, and released with a shock collar (Schultz et al. 2005) 5.3 km from the farm because she was likely nursing a litter of pups. Three other wolves (one yearling male, one adult male, one adult female) were also captured at the farm in August and were translocated 260 km from the farm. In previous years, two different wolf packs bordered the farm: the River Side Pack to the east and Chases Brook pack to the north and west. We were unable to determine which pack the pups came from and were concerned the pups might be abandoned if translocated with the adults, so they were transported to a holding pen 174.8 km from their capture site.

The holding pen consisted of a 3 m2 enclosure with an artificial den (46 × 81 × 61 cm) placed 0.3 km from the nearest human dwelling. The four pups were fed a mixture of 60% venison, 40% dry dog food (Tuffy's, Division of H. J. Heinz, Perham, Minnesota 56573, USA). All four pups were given a 0.5 ml injection of Gentocin (Schering-Plough Animal Health Corp. Kenilworth, New Jersey 07033) daily for 21 days to treat trap-related injuries.

On 16 August 2001, a White-tailed Deer (*Odocoileus virginianus*) carcass was placed by a rendezvous site commonly used by the Bootjack Lake Pack (BJLP). On 20 July 2001 pups and adult wolves responded on a howling survey from the rendezvous

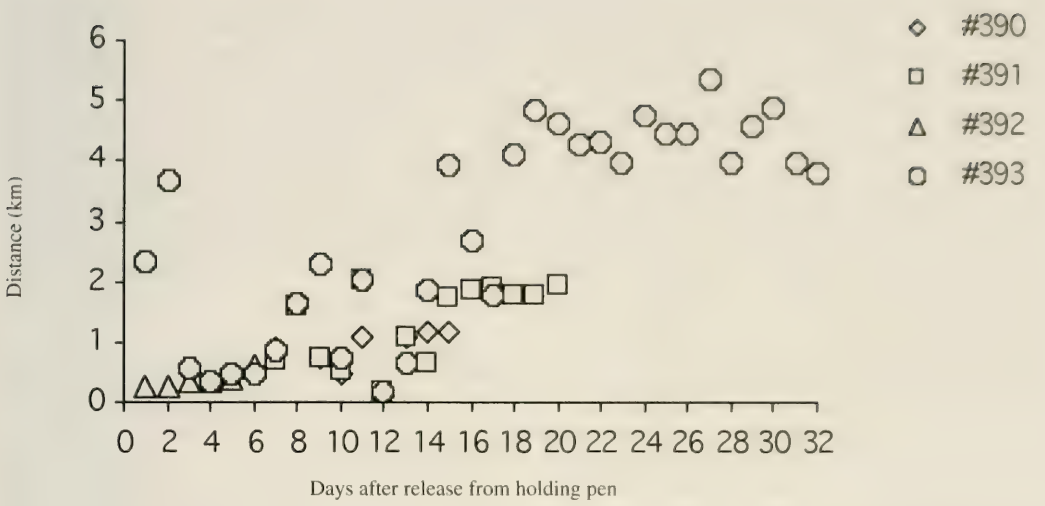

FIGURE 1. Daily distance pups F390, M391, M392 and F393 moved from holding pen, (28 August to 29 September 2001).

site and on 21 July 2001 an industrial forest employee saw one gray and three black wolf pups 200 m southeast of the rendezvous site.

On 19 August 2001 a new holding pen of the same size was erected 30 m from the deer carcass drop site, next to the rendezvous site. On 20 August 2001 all four pups were weighed (10.9 – 11.8 kg) and fitted with radio tracking collars (Telonics Inc., Mesa, Arizona 85204-6699 USA). The radio collars were lined with Rockford 3319 foam rubber (Rockford Supply Inc. 1500 Washington Avenue, North Minneapolis, Minnesota 55411) to compensate for neck growth. The four pups were then transported to the new holding pen, and another deer carcass was dropped off. Three adult wolves from the BJLP spontaneously howled while the pups were being placed in the new pen.

On 28 August 2001, all four pups were given a 1-ml external treatment of Revolution (Pfizer Animal Health Exton, Pennsylvania 19341, USA, Division of Pfizer Inc., New York 10017) and 0.5-ml subcutaneous injection of Ivermectin (MSD-AGVET, Division of Merck & Co., Rahway, New Jersey 107065, USA) to kill a heavy infestation of lice (*Trichodectes canis*).

Wolves F393 and M392 were released from the holding pen on 28 August 2001, and wolves F390 and M391 were released on 3 September 2001. Venison and dry dog food were placed in the holding pen every day for the next five days. Deer carcasses were dropped off every 2-3 days for the next 17 days. All pups were located one or more times daily for the first 32 days after release and one or more times weekly thereafter.

Necropsies on all pups that died were performed by wildlife disease specialists and pathologists at the United States Geological Survey (USGS) National Wildlife Health Center in Madison, Wisconsin.

Results

The pups repeatedly returned to feed on the deer carcasses and remained within 4.0 km of the release site for the first 14 days (Figure 1). Adult wolf tracks were observed at the deer carcasses on 5 and 8 September 2001, and on 9 September 2001 an adult wolf was observed by the deer carcass drop site, confirming members of the BJLP were visiting the site.

On 3 September 2001, wolf M392 was found dead 0.4 km from the holding pen. The body was partially submerged in water on the edge of a small marsh. His carcass looked to be in good condition, did not have any external wounds, and had gained 1.5 kg from when he was collared. Necropsy results revealed congested lungs, and death probably due to bacterial pneumonia (USGS, National Wildlife Health Center, Case 17366). On 12 September 2001, wolf F390 was found dead 1.1 km from the holding pen at the edge of a northern White Cedar (*Thuja occidentalis*) swamp. F390 had deep puncture wounds to the head and throat, and a fractured skull and ribs. F390 had gained 2.4 kg from when she was collared (USGS, National Wildlife Center, Case 17394). Adult male wolf M336 of the BJLP was located at the same location as F390 on 10 September 2001, so it was assumed he or other pack members may have killed the pup.

On 17 September 2001, wolf M391 was found dead 1.9 km from the holding pen on an old Beaver (*Castor canadensis*) dam. M391 had superficial puncture wounds to the throat and lower jaw. The superficial wounds may have occurred on 10 September 2001 when M391 was located near F390 and M336. Necropsy results revealed congested lungs and death probably due to bacterial pneumonia (USGS, National

Health Wildlife Center, Case 17395). M391 had gained 2.8 kg from when he was collared. The average weight gain of all three pups from release date until their deaths was 0.21 kg per day. This was double the standard weight gain of 17 wild-caught female wolf pups (Van Ballenberghe and Mech 1975).

Wolf pups F390, M391 and M392 stayed within 1.9 km of the release pen until their death. Wolf pup F393 moved 3.7 km from the release site two days after being released but returned 3 days later. She remained within 2.7 km of the release site until 15 September 2001, when she moved 4.1 km (figure 1) and stayed within a 3.5 km2 area until 4 December 2001. She then moved 23.2 km southwest of the holding pen. Pilots observed F393 with two other wolves on 8 January 2002, but she did not appear to establish a new territory during the winter of 2002.

In spring 2002, wolf F393 dispersed westward and by summer had settled into the Long Lake Pack area 106 km southwest of the Bootjack Lake Pack. On 1 August 2005, wolf F393 was captured and euthanized on a depredation complaint. Five placental scars were observed on F393 necropsy, confirming she apparently raised pups in 2004 and 2005 (USGS, National Wildlife Health Center, Case 19680).

Discussion

The cross-fostering attempt was not successful, but one pup (25%) of the four did survive and eventually joined up with other wolves. This pup remained alive, but abandoned the Bootjack Lake Pack's territory. None of the pups joined the new pack, and three died within 15 days of release. Two of the pups (50%) had injuries which were assumed to have been inflicted by Wolves from the BJLP. The cross-fostering attempt might have been more successful if the pups had been introduced to a pack adjacent to their natal pack's territory where there may have been some interaction between packs (Hamilton 1964). Perhaps if the pups had been placed in the BJLP's territory earlier and kept in the holding pen longer, the BJLP wolves would have become more bonded to them (Bradley et al. 2005). We also assume that pup mortality may be high on this type of introduction, as in bears, and should only be attempted under extreme circumstances.

Acknowledgments

Persons assisting in the capture and monitoring of the four wolf pups included Michael Weinfurter, Edward Zwisik and Mathew Nilson. Wolf monitoring was funded by the Chequamegon Nation Forest, U.S. Fish and Wildlife Service, Section 6 Grant, Federal Aid in Wildlife Restoration Project W-145-R and Wisconsin Endangered Species Fund. Depredating wolves were captured by personnel of United States Department of Agricuture-APHIS-WildlifeServices under the direction of Robert Willging. A special thanks to Nancy Thomas, Valerie Shearn-Bochsler, and Grace McLaughlin at the USGS, National Wildlife Health Center Madison, Wisconsin for necropsy results. We also thank Ellen Heilhecker for literature research.

Abandoned Seabird Eggs as a Calcium Source for Terrestrial Gastropods

ALEXANDER L. BOND[1,2] and ANTONY W. DIAMOND[1]

[1] Atlantic Cooperative Wildlife Ecology Research Network (ACWERN) and Department of Biology, University of New Brunswick, P.O. Box 4400, Fredericton, New Brunswick E3B 5A3

[2] Current address: Department of Biology, Memorial University of Newfoundland, St. John's, Newfoundland and Labrador, A1B 3X9 Canada; Corresponding author; e-mail: abond@mun.ca

Bond, Alexander L., and Antony W. Diamond 2007. Abandoned seabird eggs as a calcium source for terrestrial gastropods. Canadian Field-Naturalist 121(4): 433-435.

Birds' use of terrestrial gastropods to supplement calcium for egg formation has been well documented, but the reverse, gastropods using avian eggshells as a calcium source, has not been recorded previously. We collected Arctic Tern, *Sterna paradisaea*, eggs, abandoned in July 2006, that were found to have many terrestrial gastropods on the surface, and it appeared as though the outer eggshell layers were removed. Using scanning electron microscopy, we compared "grazed" and "ungrazed" sections of the same shell with eggshells collected in 2005 that were not attended by snails. It appears as though the snails removed the outer eggshell layers, presumably to supplement their own shell growth.

Keywords: Arctic Tern, *Sterna paradisaea*, White-lip Gardensnail, *Cepaea hortensis*, Glossy Pillar, *Cionella lubrica*, calcium, eggshell, New Brunswick

Although is it true that birds may seek to augment calcium intake during egg production (Nisbet 1997), particularly in acidified environments (Beintema et al. 1997; Brenninkmeijer et al. 1997; Mänd et al. 2000), the reverse relationship of snails exploiting an avian calcium source has not been recorded. This is likely because access by snails to avian calcium sources (i.e., eggs) is either limited during periods of nest attendance and incubation by adult birds, or because other avian calcium sources such as bones from dead chicks or eggshells ejected from the nest decompose or otherwise disappear from view.

Machias Seal Island (MSI; 44°30'N, 67°06'W) is a 9.5 ha treeless island in the Bay of Fundy, Canada, and is home to several nesting seabird species, including Arctic Tern, *Sterna paradisaea*, and Common Tern, *S. hirundo* (Diamond and Devlin 2003; Bond et al. 2007). In the summer of 2006, the tern colony was abandoned on 25 June, before any eggs hatched. Although the proximate cause likely was intense predation on tern nests by Herring Gulls, *Larus argentatus*, and Great Black-backed Gulls, *L. marinus* (AWD unpublished data), the ultimate cause is likely a decrease in available food supply, mainly 0-group Atlantic Herring, *Clupea harengus* (DFO 2005), which preceded several years of near reproductive failure for both tern species (Bond et al. 2007).

On 22 July 2006, eleven tern eggs that had not been taken by gulls were collected and it was noticed that many small land snails had attached themselves to the exterior of the tern eggs, causing surface aberrations (Figure 1). Through visual comparison with eggs not attended by snails, we wanted to determine if snails were "grazing" on the tern eggs. Snails have been observed on abandoned eggs at tern colonies in southern New England (I. C. T. Nisbet, personal communication, 2006), but their effects on the eggs' exterior was not examined.

Our objective was to use electron microscopy to compare visually the surface of eggshells attended by snails with sections of the same eggshell that were unattended and with shells of eggs that had no snails present at all.

Methods

Tern eggs were collected on 22 July 2006 from Machias Seal Island, Bay of Fundy, Canada. Eggs were taken from nests located in the central vegetated portion of the island, where Canada Bluejoint, *Calamagrostis canadensis*, dominates and is kept short by regular mowing. Areas immediately surrounding the tern nests were not mowed to avoid damage to the nests' contents. Once the eggs were collected, snails were removed from the eggs. Eggs were wrapped individually in cellophane, frozen at -18°C and transported to the University of New Brunswick, Fredericton, for analysis. Snails were similarly frozen in sterile polythene bags, and transported.

Eggshell samples were prepared and examined using a JEOL JSM 6400 scanning electron microscope with an operating voltage of 7 kV at the Microscopy and Microanalysis Facility at the University of New Brunswick. Small sections of shell were mounted on aluminium stubs using carbon tape and carbon paste to properly ground the specimens, and sputter-coated with approximately 50 nm of gold. Photographs were taken at either 90° (from directly above) or at 50° to the electron beam.

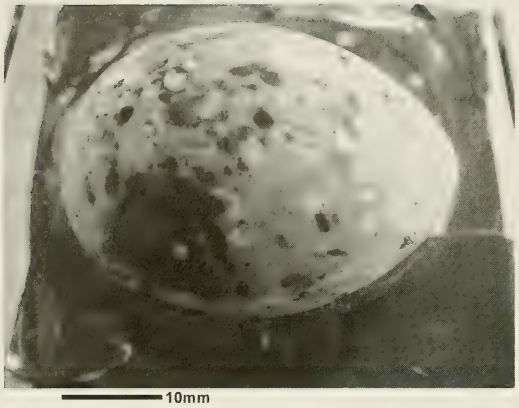

FIGURE 1. Abandoned Arctic Tern egg. Light circular marks on the shell's surface were the locations of snails.

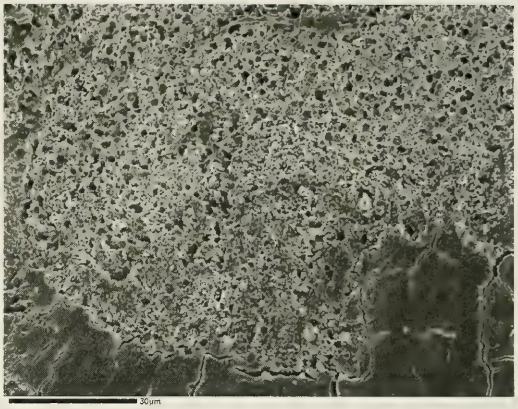

FIGURE 2. Grazed (top) and ungrazed areas (extreme bottom) of an Arctic Tern egg. Electron micrograph taken at 90° to electron beam.

Results and Discussion

Gastropods were identified at the New Brunswick Museum (Saint John, New Brunswick) as *Cionella lumbria* (Glossy Pillar; Stylommatophora: Cionellidae), a common terrestrial gastropod in the northeastern United States (Martin 2000), and immature or hatchling *Cepaea hortensis* (White-lip Gardensnail; Stylommatophora: Helicidae), which is common on several islands in the Bay of Fundy (D. McAlpine, New Brunswick Museum, St. John, personal communication, 2006).

Individual eggs had between 1 and 14 gastropods present (mean ± SD, 4.18 ± 3.79), with *Cepacaea hortensis* being more common (40 of 46 total gastropods found on ten eggs), and the remainder being *Cionella lumbria* (6 of 46, present on three eggs). Linear regression found no relationship between snail abundance and egg size (breadth or length).

Areas on the tern eggshell that were "grazed" by the snails had the outer surface layer removed, exposing the radially oriented crystals immediately beneath the tangentially-oriented crystals that form the shells' surface (Becking 1975; Figure 2), whereas ungrazed areas (Figure 3 top) appeared similar to shells collected in 2005 (Figure 3 bottom). An examination of the interface of the grazed and non-grazed areas with the photograph taken at 50° to the electron beam shows a "landscape" view, with the grazed areas lower than non-grazed areas (Figure 4), indicating the removal of the outer calcified layer of the eggshell by the snails. This outer crystalline layer varies in thickness from 1 to 10 mm in other bird species (Tyler 1964; Becking 1975), but it has not been examined previously in any of the Laridae.

It is unlikely that this method of calcium acquisition by snails would occur had the terns remained and incubated their nests through to hatching. Arctic Terns incubate their clutch of 1-3 eggs for approximately 21-23 days (Hatch 2002). Paquet (2001) found that incubating terns spent 41% of their daily time budget incubating the egg, and that for more than 80% of the time, at least one adult in the pair was tending the eggs. This implies that any colonization attempt by gastropods would be unsuccessful because the egg would be unattended and accessible by the gastropods very little of the time. If such colonization did occur, the contact with the adult during incubation would likely remove the gastropod from the eggshell.

It is likely that the large number of abandoned eggs drew our attention to what could be a common phenomenon at the microscopic level. Seabirds can alter soil chemistry drastically (Mizutani et al. 1991), and it is likely that eggshells ejected from nests and bones from dead adults and chicks provide a reliable source of calcium enrichment, which could be accessed by the snails.

Rainfall on Machias Seal Island was well above average in 2006, with 469 mm between 15 May and 18 August, compared with the mean (± S.E.) of 225.0 mm (± 29.2) over the previous 12 years (Bond et al. 2007), and this likely contributed to high productivity among the snails (Barrientos 2000; Tattersfield et al. 2001).

The gastropods' use of avian eggs as a calcium source is a reversal of the more typical relationship between birds and molluscs, as birds in acidified environments are often documented consuming molluscs to supplement production of calcium for their eggs (Beintema et al. 1997; Brenninkmeijer et al. 1997; Nisbet 1997; Mänd et al. 2000). It is our belief, though, that this behaviour in the snails is likely to be regular or frequent in occurrence, and that the snails are seeking new and abundant natural sources of calcium to promote shell growth, including abandoned eggs.

Fish-line Entanglement of Nesting Mourning Dove, *Zenaida macroura*

GLENN H. PARKER and CHRIS G. BLOMME

Department of Biology, Laurentian University, Sudbury, Ontario P3E 2C6 Canada

Parker, Glenn H., and Chris G. Blomme. 2007. Fish-line entanglement of nesting Mourning Dove, *Zenaida macroura*. Canadian Field-Naturalist 121(4): 436-437.

We give a detailed account of monofilament entanglement in nesting material of a gravid female Mourning Dove (*Zenaida macroura*) which resulted in death. Such incidents substantiate the hazards of anthropogenic materials and the need to dispose of them with due diligence.

Key Words: *Zenaida macroura,* Mourning Dove, monofilament, fish line, avian anthropogenic hazards.

Mourning Doves (*Zenaida macroura*) nest annually in the town of Val Therese (46°39'N, 81°01'W), Sudbury District, Ontario. On 12 April 2005, an unusual flash of movement attracted my eye to the neighbour's 15-meter-tall Blue Spruce (*Picea pungens*). Upon more careful inspection, I noticed a Mourning Dove hanging unnaturally among the interior boughs of the spruce. An additional bird was present, presumed to be the other of a mated pair. Entering under the boughs, I noticed that the lifeless dove was hanging from a thread of monofilament fish line to which it had succumbed following an obvious struggle. One meter above the dangling bird, situated on a branch 1.75 meters from the trunk and 2.75 meters off the ground, was a fully-formed nest.

The hanging bird was a female Mourning Dove weighing 124 grams. Autopsy revealed that the bird was in a healthy state; the crop was full of wild seeds and normal amounts of adipose tissue were present throughout the body. A fully-developed egg with a near-calcified shell was present in the oviduct, indicating that egg laying would probably have occurred within a day. The nest was well-formed but empty, implying that nest construction had been completed and egg laying was about to commence.

The fish line was of ten-pound test and consisted of two separate lengths each entwined in the nesting material. The smaller piece measured 25 centimeters and the longer piece 2.5 meters. The longer piece was woven into the nest at mid-level, indicating that it had been incorporated during nest building rather than added later. The bird had become entangled with a portion of the longer line. The fish line ran between the sixth and seventh primary on the underside of the right wing, then looped over the dorsal surface of the humerus to the neck where it was looped completely around the neck. Subsequently, the line stretched to the left wing which was wrapped twice very close to the body, and then extended from the dorsum of the bird as a free end. The bird was dangling from the line anchored within the nest, with a single upwardly-extended wing and a severely down-turned head and neck directed into the pit of the extended wing. Strangulation as a result of the initial entanglement and panic response is inferred as the cause of death.

Various anthropogenic hazards have been reported to contribute to mortality in Mourning Doves, including decapitation from power lines, utility lines and TV towers while in flight (Stoddard and Norris 1967), window strikes (Terres 1980), and vehicle, train and aircraft strikes (Terres 1980). Monofilament fish line entanglement has been well documented in waterfowl, marine birds. (Manville 2005; King et al. 1979) and loons *Gavia* spp. (Sidor et al 2003) as well as noted in doves on previous occasions (Sadler 1993; Mirarchi and Baskett 1994). The tendency of certain species to incorporate foreign anthropogenic materials during nest building, including fine wires as noted in dove nests reported by Peck and James (1983), appears to predispose such species to higher risk levels. Specific details of incident reports appear to be lacking in much of the literature. This note serves to further document the use of discarded fish line (a non-natural nesting material) and its potential contribution to mortality in a common tree-nesting species.

Cott, Peter A. and Neil J. Mochnacz. 2007. Bull Trout, *Salvelinus confluentus*, and North American Porcupine, *Erethizon dorsatum*, interaction in the Mackenzie Mountains, Northwest Territories. Canadian Field-Naturalist 121(4): 438-439.

Evidence of an interaction between a Bull Trout (*Salvelinus confluentus*) and a North American Porcupine (*Erethizon dorsatum*), was observed during a fisheries survey in the Mackenzie Mountains, Northwest Territories. A male Bull Trout with porcupine quills imbedded in its mouth was collected. It is speculated that this occurred when the trout was aggressively defending its territory from a perceived threat – a swimming porcupine. This is the first documented account of an interaction between a fish and a porcupine.

Key Words: Bull Trout, *Salvelinus confluentus*, North American Porcupine, *Erethizon dorsatum*, prey, interaction, diet, Northwest Territories, Mackenzie Mountains, Mackenzie Valley.

We report an interaction between a Bull Trout (*Salvelinus confluentus*) and a North American Porcupine (*Erethizon dorsatum*), two animals that, due to different life history requirements, would rarely be in contact.

The Bull Trout is a native salmonid (genus *Salvelinus*) occurring in streams, rivers and lakes across western North America. The species' range extends from northern California to the central Northwest Territories [NWT] (Haas and McPhail 1991; Reist et al. 2002; Mochnacz et al. 2004; Stewart et al. 2007a). Bull Trout are a top level predator consuming a variety of prey items ranging from insects to small mammals (Stewart et al. 2007b). North American Porcupines are large rodents, weighing up to 14 kg and are widely distributed from the Arctic Ocean to northern Mexico (Roze 1989). Porcupines occupy a variety of habitat types and are considered generalist herbivores (Roze 1989). Their dorsal surface is covered with modified guard hairs in the form of barbed quills, which serve as protection against predators. Predators include the Wolf (*Canis lupus*), Coyote (*Canis latrans*), Wolverine (*Gulo gulo*), Fisher (*Martes pennanti*), Cougar (*Puma concolor*), Canada Lynx (*Lynx canadensis*), Bobcat (*Lynx rufus*), and Great Horned Owl (*Bubo virginianus*) (Roze 1989). When a porcupine is attacked, the quills are driven into the assailant and released from the porcupine's skin, allowing the porcupine opportunity to escape (Roze 2002).

On 1 September 2007, during a field survey to delineate the distribution and assess habitat use of Bull Trout in the Mackenzie Mountains, NWT, two male Bull Trout were angled from a pool in an unnamed tributary of the Redstone River (63°39'001"N, 125° 23'414"W). The larger fish (fork length 583 mm, 2022 g) had four Porcupine quills embedded in its mouth. The quills were in the thin skin covering the upper mandible (Figure 1), with no quills in the esophagus or stomach, which suggested that the Bull Trout had bitten a porcupine, rather than scavenged off a carcass. Only fish remains were found in the trout's stomach. The size and colouration of the quills were consistent with those from the side of a porcu-

FIGURE 1. A Bull Trout (*Salvelinus confluentus*) collected from an unnamed stream in the Mackenzie Mountains, Northwest Territories, impaled by the quills of a North American Porcupine (*Erethizon dorsatum*).

pines' tail, suggesting a defensive interaction (U. Roze, Queens College, Flushing, New York, personal communication 2007). For a Bull Trout to encounter a porcupine, the latter would either have to be wading or swimming across a stream, or less likely, floating dead down a stream. Porcupines are known to swim or otherwise traverse watercourses to access different parts of their range (Murie 1926; Roze 1989). When a porcupine swims, the majority of the body is below water, with the head and some of the back and tail visible above the surface, much like a Beaver (*Castor canadensis*) (U. Roze, personal communication 2007). Bull Trout often live in environments that have sparse food resources and are, therefore, opportunistic predators (Stewart et al. 2007b). However, given a porcupine's size it is unlikely that it was a potential food source. A more plausible explanation is that the Bull Trout was defending its territory against the porcupine which the fish interpreted as a threat. Bull Trout are very aggressive, particularly during spawning, and have attacked SCUBA divers during *in situ* spawning surveys (J. Stewart, Fisheries and Oceans Canada, Winnipeg, personal communication, 2007). The time frame of the survey and temperature observed (6.0°C) are both within the preferred ranges for spawning Bull Trout in the NWT (Mochnacz et al. 2004) and further south (Baxter and McPhail 1996).

This is the first record of a Bull Trout, or perhaps any fish, attacking a North American Porcupine. Although an interaction between these two species is certainly a rare event, the fact that it occurred is evidence of the aggressive behavior of Bull Trout, and the unusual and unforeseen linkages that can occur within a given ecosystem.

Thus Canadian dollars are CAD, United States dollars are USD, Euros are EUR, China Yuan Renminbi are CNY, Australian dollars a AUD and so on. You will find these are the codes now used by financial institutions and internet currency converters. I will include an updated note for the next few issues as a reminder.

ZOOLOGY

The Ecology & Behavior of Amphibians

By Kentwood D. Wells. 2007. University of Chicago Press, 1427 East 60th Street, Chicago, Ilinois 60637. 1148 pages. 75.00 USD.

This massive volume synthesizes knowledge gained through researcher Wells' extensive field experience and total immersion in the literature focussed on habitats and habits of a generous sampling from the approximately 6000 species of amphibians now recognized in the world. Its extended gestation time began with conception and partial drafts in the early 1980s. The period since has been one of ever-increasing research and publication by a growing number of researchers resulting in exponential additions to the number of species recognized and, especially, the volume of information on them. But simultaneously, it has been a time of realization of the fragility of the world's amphibian fauna and the decline, sometimes the extinction, of many species in many parts of the world ascribed to a variety of causes. Wells has been long-recognized as one of the most productive and original researchers on amphibians of this period.

His book has 16 chapters, the first on phylogeny, classification, and morphological evolution, followed by ones on water relations, temperature relations, respiration, metabolism and energetics, movements and orientation, anuran vocal communication, mating systems and sexual selection in anurans, communication and social behavior of urodeles and caecilians, the natural history of amphibian reproduction, parental care, ecology and behavior of amphibian larvae, complex life cycles and ecology of amphibian metamorphosis, amphibians and their predators, the ecology of amphibian communities, and, finally, the conservation of amphibians. The reference section well reflects the vastness of the information in the volume itself – the two-column format occupies 238 pages, the length of many books. Included are many, but by no means a comprehensive selection of relevant papers by Canadian herpetologists. Finally, a 64-page index concludes the text. It is unfortunate that the initial chapter summarizing classification was completed before Frost and his colleagues (2006 American Museum of Natural History Bulletin 297) published their extensive reassessment of amphibia relationships which proposed many changes in nomenclature that could not be evaluated for possible inclusion here. This is not a serious flaw as the book's overall emphasis is not on systematics.

Wells has deftly managed both a detailed and a readable reference and primer for study of amphibians in nature. Its price and mass (approximately 11×8.5×2.2 inches or 286×220×60 mm) will doubtless keep it from many a naturalist's library shelves, except for the few primarily focussed on amphibians who have ample disposable income (perhaps not a common combination), but it is a must for every university biology and federal and provincial government environment department and should be read by all biology students and conservation-charged public servants. Graduate students focussed on amphibians or vanishing habitats in particular, will find this a treasure of the research to date, and a gold mine of background information to inspire future research projects.

The Amphibians and Reptiles of New York State: Identification, Natural History, and Conservation

By James P. Gibbs, Alvin R. Breisch, Peter K. Ducey, Glenn Johnson, John L. Behler, and Richard C. Bothner. 2007. Oxford University Press, 198 Madison Avenue, New York, New York 10016. 422 pages. 34.50 USD.

Lack of an authoritative field guide to the herpetology of the state of New York has been a glaring vacuum in texts on the northeastern United States throughout the last century. This, despite its relatively large size for a northeastern state (49 108 square miles or 127 189 km^2), and being the home of many exceptionally prominent herpetologists over the last century. The state had been among the earliest to be given a comprehensive scientific treatment when James DeKay (for whom the snake *Storeria dekayi* is named)

included amphibians and reptiles in his *Zoology of New York* in 1842. Almost 100 years later (in 1941) it received the most through state monograph on a single group, the *Salamanders of New York* by Sherman Bishop, Rochester, New York. Bishop followed this with a handbook to all North American salamanders. Others included, in the first half of the 1900s, Raymond Ditmars, New York, who wrote immensely popular and influential books on reptiles of North America and of the world and, Albert and Anna Wright, Ithaca, who used local studies to produce the first comprehensive data on the life histories of eastern North American frogs and toads then went on to produce North American handbooks to frogs and toads in 1933, revised in 1942 and 1949, and to snakes in 1957.

The six authors who finally have filled the need for a field guide are also New York state residents, scattered among universities, conservation departments and organizations: Gibbs at the State University of New York College of Environmental Science, Syracuse; Breisch at the New York State Department of Environmental Conservation, Albany, Ducey at the State University of New York at Cortland, Johnson at the State University of New York at Potsdam, and Bothner at St. Bonaventure University, Olean. The late John L. Behler (1933-2006) was with the Wildlife Conservation Society, Bronx. The distributional data are from the Amphibians and Reptile Atlas Project of the New York Department of Environmental Conservation which compiled 59 000 reports submitted by 1800 volunteers. The atlas also included 28 000 pre-1990 records from museums, field notes, graduate theses, and published literature.

The text covers 69 native species (18 salamanders, 14 frogs and toads, 17 turtles, 3 lizards and 17 snakes), and includes 65 distribution maps (ranges shaded, but without spot localities) and 72 colour plates (each with one to four superior, sharp photographs of pattern and life stage variants contributed by over 30 photographers). Each species account is headed with English and Scientific names followed by sections on Quick Identification, Description, Habitat, Natural History, Status and Distribution, and Other Intriguing Facts. Statements are referenced to a 39-page Literature Cited section. Many leading Canadian herpetologists are cited, among them classical studies by J. P. Bogart on ambystomid salamanders and R. J. Brooks on Snapping and Wood turtles (both at University of Guelph), M. Berrill on pesticide effects and declines (Trent University), J. Gilhen on Nova Scotia species (Nova Scotia Museum), D. M. Green on hybridization in toads (McGill University), P. J. Weatherhead, K. A. Prior, and G. Blouin-Demers on Rat Snakes (Carleton University, Environment Canada. and Ottawa University, respectively).

But the text is not just species accounts. A brief introduction summarizes the history of state herpetology and stresses the conservation theme found throughout the book. It is followed by a discussion of the state herpetofauna with a table giving, for each species, its New York Natural Heritage Program State Rank, NatureServe Global Rank, and (where applicable) its New York State and Federal Listings, exotic species sometimes reported (alligators in the sewers of New York City and beyond) and similarities and differences between amphibians and reptiles. The is a chapter on New York's environment as habitat for amphibians and reptiles with maps of ecological zones, of major lakes and rivers, of counties and major cities, and "land cover". The ecological zones are described with representative habitat photos and a table of all species and habitat types they occur in. Final chapters are Threats outlining the effects of historic overexploitation (particularly commercial harvest) and habitat loss over time, acid rain, contaminants, disease and deformities. Following chapters discuss legal protection, habitat conservation guidelines, conservation case studies, finding and studying amphibians and reptiles, folklore, and epilogue. Appendices cover the "Herp Atlas" Survey Card, and Resources (organizations and identification and general reference). A Glossary covers terms from amplexus to wetland, followed by Literature Cited and a 20-page index.

Eastern Canadian naturalists will find this book a must for their bookshelves as an excellent reference not just to the species included (species that occur in eastern Canada are also in New York) but also for conservation approaches and philosophy. It lacks only a section on care of captives, and that, I suspect, is not an oversight but deliberate, making a strong statement by its omission.

Extreme Birds

By D. Couzens. 2008. Firefly Books Ltd., 66 Leek Crescent, Richmond Hill ON L4B 1H1. 281 pages. 45 CAD Cloth.

When *Extreme Birds* arrived in the mail, it caught my attention with its dramatic, somewhat comical, cover photograph of a Shoebill. I started to nose through, looking first at the remarkable photographs, and wondering who might review this book. Then the chapter titles made me take a second look and I was hooked! I expected widest wingspan, smallest bird, longest bill and so on, but heaviest testes, biggest belly and smelliest bird took me by surprise. In the author's view the malodorous claimant is the Crested Auklet. These cute beasts are said to emit a potent, tangerine-like stink that carries for miles. I am afraid I missed that pleasure last year when we sailed by their colonies; there is an advantage or disadvantage to having a poor sense of smell.

This book not only covers the record individual characteristics, like largest and smallest, but includes three other categories. Extreme Ability covers such performance heights as fastest swimmer, best flock coordination and best mimic. Extreme behaviour describes the strangest incubation, the loveliest display and the best drummer. Finally Extreme families documents the limits of courtship, promiscuity and breeding.

Many of the author's choices will not surprise the ardent birder. The widest wingspan belongs to the Wandering Albatross. The biggest eyes [5 cm] are in the head of an Ostrich and the smallest bird is a Bee Hummingbird [5.7 cm]. So the little hummer could almost squeeze into an ostrich eye. Although the choices are obvious, the author tucks in many fascinating details. The ostrich eye is as big as an eye can be, or diffraction would cause problems. It would take 3000 Bee Humming bird eggs to equal the weight of one ostrich.

I did not realize there was a poisonous bird, the Hooded Pitohui of New Guinea. Apparently this bird absorbs batrachotoxin alkaloids from the Choresine beetles it eats. This toxin is also found in some poison-dart frogs and believed to come from their diet too.

Under the title "Classiest Colours" Couzens gives an excellent discussion of the feather colour of a turaco. This genus is the only one to make green pigment [other "green" birds use refracted light to give the impression of green] and the author covers the process in simple and elegant language.

For the whitest bird he chooses an Ivory Gull, not what came to my mind. I would say several egrets are good contenders, but my choice would be the Snow Petrel. Not only are these little birds bright white, but they have a beautiful sheen that gives them a special glow. Perhaps they did not "win" this category as the Great Egret is cited for the best grooming aids [its powder down and pectinated, comb toe] while the Snow Petrel gets the "Most relaxed attitude to breeding." However the Barn Swallow gets two citations as "Sexiest tail" and Canniest false alarm."

The author often chooses one species, but the same remarks can be made of others in the genus. The longest legs are not confined to the Lesser Flamingo but are characteristic of all flamingos. Similarly at least the Variable Pitohui and the Brown Pitohui [there are six in the genus] are poisonous as well as the Hooded Pitohui. Indeed Blue-capped Ifritas carry the same toxin.

The photos, one for each species, come from professional stock companies. Therefore they are superb. It is futile to try and pick the best ones, but those that caught my attention were Lesser Spotted Eagle [so majestic], Clarke's Nutcracker [so homely], Western Capercaillie [so haughty] and the Barn Owl [such a beautiful bird]. The photo of the Red-crowned Crane is so artistic it could be a Japanese woodcut by Hokusai or Hiroshige.

I usually read bird books to learn something. While this is a pleasurable act, the primary focus is not amusement, but information. I read this book because it is fun. Even when I knew the facts, such as the Emperor Penguin's unbelievable fast, I enjoyed this author's version of the tale. It was even better when I was learning something new, like the Great Crested Grebe's passion for eating its own feathers. So if you want to know the biggest, the fastest, the smallest, best nest builders, weirdest matings and who dives the deepest or flies the highest, then this is the book for you. Even non-birder trivia fans will get great enjoyment.

Oh yes, and the heaviest testes [8% of its body mass and heavier than its brain] record is held by the Alpine Accentor. For good reason too, but you really should read the book to find out why! And then there is the bird that f*rts to catch its food – but that is another story.

Cranes: A Natural History of a Bird in Crisis

By Janice M. Hughes. 2008. Firefly Books Ltd. 66 Leek Crescent, Richmond Hill, Ontario L4B 1H1 Canada. 256 pages. 45 CAD Cloth.

Firefly Books produces well-illustrated nature books featuring larger format, glossy paper, and generally readable text. Cranes are exciting birds, and they have captured mankind's imagination for millennia, so they make good subjects for a book of this character. It is written by Janice Hughes, an Associate Professor at Lakehead University.

With a title like *Cranes* one might expect the subtitle to refer to a "Family in Crisis" but in fact the "Bird" referred to is the Whooping Crane, and despite the emphasis on the dust jacket on cranes as a group, two-thirds of the text is devoted to the history of this one species. Chapters one and six cover the family as a whole, the first outlining their natural history, and the second profiles of the 15 species. Perhaps appropriately, the natural history section includes extensive coverage of the species' relationship to man, starting with a section on mythology, folklore and cultural importance, and concluding with demographics and threats, and crane conservation. In chapter 6 each species is assigned two pages in a smaller type-face, including a range map and a rather small [~3×5 inch] picture.

Chapters 2 through 5 chronicle, first the decline of the Whooping Crane, followed by accounts of its recovery, discussing in turn the bird's population and migration, and concluding with a summing-up. Because the threats to cranes are mentioned in a number of sections, there tends to be some repetition of material. Two appendices provide the World Conservation Union ratings of crane status, and wild Whooping Crane peak winter counts from 1938-1971.

I was rather disappointed by the book, mainly because the Whooping Crane sections are so dominant in it that I had a feeling the rest of the species were almost an after-thought. The family is a rather homogeneous one, so treating the natural history of the birds as a group is reasonable, but the two-page summaries are just that – summaries – and the illustrations in them are inadequate given the scope and size of the book. In fact, the pictures in general are not up to the standard one expects from a book of this type. Many of the ones in my copy are a little off, lacking sharpness, and some are no more than cropped versions of pictures that appear earlier.

The text is rather uneven. Some parts are rather plodding. The author lapses periodically into jargon and then, for those who might not understand, pops in a brief explanation. Why use the term in the first place? At its best, however, it is well-written, even eloquent, especially in sections discussing the plight of cranes. The Whooping Crane history is given in considerable detail, even to the extent of outlining the events leading to the formation of the Audubon movement.

Those seeking a comprehensive treatment of the world's cranes will find this book wanting. If you are interested in the fascinating account of the collapse and gradual recovery of the Whooping Crane in North America, coupled with an overview of cranes generally, then this could be a good book to acquire.

CLIVE E. GOODWIN

Marine Mammals of the Pacific Northwest: A Concise and Comprehensive Waterproof Guide

By P. A. Folkens. 2001. Harbour Publishing, P.O. Box 219, Madeira Park, British Columbia V0N 2H0. 8 pages. 9.95 CAD – (synthetic film).

The increasing development of the whale-watching industry has resulted in the demand for, and creation of, books and identification guides for sea mammals, seabirds and the marine ecosystem. In this regard, and looking back on a history of whale-watching for over 90 years, the coast of British Columbia has received most of the publication activity in Canada.

Despite its catchy title, this guide by Pieter Arend Folkens is more a leaflet of a guide. It consists of three text pages and five pages of drawings and photos full of information for the whale watcher in the field. Although the leaflet is printed on "waterproof, UV resistant synthetic film made from a 100% recyclable, environmentally inert material containing no forest products (similar to milk jugs)", the user might actually have difficulties using it on an offshore whale watching trip during periods of stronger wind or higher waves; the light leaflet could easily fly away and the small print is hard to read when on a rolling boat. However, the compressed text gives a nice summary and overview on 31 sea mammal species in the area; it even mentions Steller's Sea Cow, which was hunted to extinction by 1768. In addition, major whale watching locations in British Columbia and Alaska are named, but none are reported really for Oregon and Washington (as the title would imply).

Most of the eight pages of the field guide are devoted to drawings and to fine pictures from the author and several others. The reader might find the distinction between *Mysticetes* (Baleen Whales), *Odontocetes* (Toothed Whales) and Small Cetaceans a little unclear from the arrangements of the drawings. Very helpful and informative is the page about "Common visible behaviours and terms" allowing to link sea mammal sightings to a classified set of behaviour types. Helpful also is that images of fluke displays are presented for species that are known to show such a behaviour. Even the body sizes of newborn sea mammals are given. All measurements are made in SI units, and the conversion factor for feet is provided.

Of interest to the general audience might be the section "Marine Mammal Watching Guidelines", also presented on the web http://www.fakr.noaa.gov/protectedresources/mmviewingguide.html (Note that the old URL www.nmfs.gov/prot_res.html and given in the guide was updated). In addition, contact addresses and a web address (revised to http://www.fakr.noaa.gov/protectedresources/strandings.htm) are given for sightings of stranded sea mammals (Department of Fisheries and Oceans Canada, 800 4654336; or the Whale Reporting & Stranding Line 800 665 5939).

As found in many other field guides, the text suggests some field marks and details for species identification and separation that normal whale watchers might not be able to apply, or which are not really realistic. For instance, Sei Whales are supposed to be differentiated from Fin Whales by a fin angle of over 45 degrees; male Beaked Whales (genus *Mesoplodon*) ideally can be identified by the location of teeth and jaw line (which is for most of the time covered by the ocean); phocids (true seals) differ from otariids (Sea Lions and Fur Seals) by their hair and small nails on their foreflippers. Overall, features like these might be very hard to recognize for the untrained as well as for the trained observer, particularly when observations are done for moving animals, from a shaky boat far away and with binoculars. Rather than focussing on classical small-scale features, outlining the use of proportions and shapes could be more useful for telling species apart. Counterproductive for a field guide might be the point that Beaked Whales, the species group that lacks most knowledge on distribution and where whale watchers could indeed contribute greatly to science, are described as the "most difficult whales to identify correctly"; no further help or details are given for the interested whale watcher. For my taste, the "Habitat and Symbol Keys" that are supposed "to

narrow possibilities in a particular area" and link sea mammals with "habitat" are not really helpful since many whales migrate across habitats anyway and since the regular observer has no real way to tell "temperate" habitats apart from "cool temperate" ones. The meaning of the orange W habitat class presented for the False Killer Whale will likely remain a mystery to the reader because its meaning is nowhere explained in the guide. For pinnipeds, their "calls" and the mentioning of rookeries could have been helpful.

Overall, it appears that this "guide" is an excerpt of a better and larger guide book from the same author. It is useable in the field, but does not replace the real and classical guide books.

FALK HUETTMANN

Centre for Wildlife Ecology, Biology Department, Simon Fraser University, 8888 University Drive, Burnaby, British Columbia V5A 1S6 Canada

Reptiles and Amphibians of Canada

By Chris Fisher, Amanda Joynt, and Ronald J. Brooks. 2007. Lone Pine Publishing, 206, 10426 – 81 Avenue, Edmonton, Alberta T6E 1X5. 208 pages. 18.50 CAD.

It has been 24 years since the first comprehensive one-volume guide to all Canadian amphibians and reptiles known at the time appeared (Cook 1984) and that is now badly out-of-date and, fortunately, out-of-print. There have been new guides to several provinces since and a highly popularized superficial attempt for the entire country by Bumstead (2003).

For this new effort, only the third author, the legendary Ron Brooks of the University of Guelph will be very familiar to most Canadian herpetologists. Brooks has long been a CITES committee member and crusader and has made an extensive ecological contribution with a legion of graduate students conducting studies at Algonquin Park and selected central and southern Ontario sites. These have produced new insights into the lives of turtles and aquatic frogs in eastern Canada and one especially endangered snake (the Blue Racer). The other two authors have BScs from the University of Alberta. Chris Fisher is a writer of wildlife articles and field guides and lecturer on wildlife. Amanda Joynt, an ecologist from the Okanagan Valley, was a technician with Parks Canada and Canadian Wildlife Service, followed by writing full time for Lone Pine publishing, ecological surveys including rare plants in South Dakota, and direction (2004-2006) of Children in Wilderness Malawi, southern Africa. She now is a biologist for Fisheries and Oceans Canada in Inuvik, Northwest Territories.

The book is traditionally organized and opens with the mandatory acknowledgements, including one to Ron Brooks, odd in that he is also a coauthor. There is a very useful "Species at a glance" which gives a miniature reproduction of the text illustration, species by species, together with size, and account page number. The 12-page Introduction briefly highlights the antiquity of the groups and their characteristics. A map plots the location of selected national and provincial parks in Canada. This is followed by a summation of major habitats from the temperate west coast to the Maritimes, a discussion titled "the good, the bad and the misconceptions", and another on the general harmlessness of most species as well as the negative aspects of keeping native species (not the least of which is that in most provinces, is illegal to keep many species except under permit from resource departments). A few words on conservation are followed by the headings used in the species accounts. The latter are the bulk of the book (150 pages) and cover both native and introduced species: 11 freshwater or terrestrial turtles and 4 marine ones, 7 lizards, 26 snakes, 21 salamanders, and 25 frogs (including toads and treefrogs, etc.). Three of the turtles and are introduced or likely so, and two of these probably no longer occur, one lizard is introduced and one apparently extirpated, and one snake (Timber Rattlesnake) is extirpated.

Each species account is dominated by an enlarged colour drawing of an adult, and these vary from very good to embarrassingly bad. Some of the snakes, turtles and frogs are among the excellent, some salamanders and virtually all the lizards are poor, the latter particularly washed-out, among other faults. The Common Garter Snake represented seems to be a particularly odd colour pattern (a Pacific region variant?) that will be unrecognized in most of the country. The Plains Garter Snake is very pale, typical of the southern and eastern portions of the range mostly beyond Canada, while the "Eastern Ribbon Snake" on the next page matches the majority of Canadian specimens of plains species. In Canada, Ribbon Snakes rarely have an orange dorsal stripe (I know of only one report) like the one pictured; the lateral stripe is usually prominently bordered below by chocolate, and overall it is more slender. Among other snakes particularly poorly done are the Red-bellied, Brown, and Green snakes. The species accounts themselves lead with English and scientific names followed by a casual informal introduction, then a paragraph ID (identification), and one or two lines on Length, Distribution (with a tiny map of Canadian range), Habitat, Activity Patterns, Reproduction, Food, Similar Species, French Name, and a Did You Know sidebar, the latter focussed on some additional fact regarded as particularly remarkable. Each native and existing species is given two facing pages. The marine turtles (designated "vagrant species") fare even less well, with only a half page each, and the introduced or extirpated ones only somewhat better at one page each. The format of necessity means that only the briefest information can be given for each. Sometimes these have little Canadian relevance. An example is the statement

that the Small-mouthed Salamander "often" shares breeding ponds with Spotted Salamanders. Presumably this applies to United States populations as in Canada the Small-mouthed Salamander has been recorded only on Pelee Island where Spotted Salamanders apparently do not occur. But omitted from the Small-mouthed Salamander account is mention of its extensive hybridization with Blue-spotted Salamanders on Pelee Island although elsewhere the hybridization of Blue-spotted with Jefferson salamanders is recognized.

On the positive side, this book does have all the species we know in Canada to date with distributions, many interesting highlights, and very colourful pictures. These will be found useful by some casually interested uncritical naturalists. However, it is no substitute for the many carefully researched and more comprehensive, within their more limited areas covered, provincial guides available for amphibians and reptiles.

Guides and Reference to the (1) Snakes, (2) Crocodilians, Turtles, and Lizards (3) Amphibians, of Eastern and Central North America (North of Mexico)

By R. C. Bartlett and Patricia P. Bartlett. 2005 (1), 2006(2&3). University Press of Florida, 15 NW 15th Street, Gainesville, Florida 32611. 342 (1), 316 (2), 283 (3) pages. 29.95 USD each.

The Bartlett team has produced a number of earlier books: *A Field Guide to Florida Reptiles*, *Reptiles and Amphibians of the Amazon: An Ecotourists Guide* (2003), and *Florida Snakes: A Guide to Their Identification and Habits* (2003). R. D. Bartlett, veteran herpetoculturist/herpetologist, founder of the Reptilian Breeding and Research Institute, boasts over 40 years writing and photographing, including more than 500 articles in magazines such as *The Tropical Fish Hobbyist*, *Reptiles*, and *Reptile and Amphibian*. Patricia Bartlett, former director of the Fort Myers Historical Museum, is an editor and writer who, in addition to coauthoring 12 books with R.D.B., also wrote *A Dictionary of Sharks*.

In these present volumes, the Bartletts have broadened their horizons and compiled a herpetofauna reference in three volumes which cover the entire eastern and central United States and adjacent Canada from the Atlantic to the tier of mid-western states from North Dakota to Texas. However, their southern bias persists. Species which range far north of the U.S. border have only the southern portion of their Canadian range shown on the generally crude distribution maps which only casually outline Canada, with the northern potions of the Canadian-based range are often cut off. No Canadian-based authors are included in the references, despite the many that have studied species included, some even from U.S. populations as well as Canadian material.

Each book has a brief Species List, a Preface and Introduction to the group(s) included. The bulk of the texts are accounts arranged by family and within these by related groups of species, and then individual species accounts. The later includes English and Scientific name followed by sections on Toxicity/Disposition (Snakes), Abundance/Range, Habitat, Size, Identifying features, Voice (in crocodilians and frogs), and Similar Species, Comments, and Additional Subspecies. There is a rather eclectic selection here sometimes of subspecies far to the west of the limits set for the book. There is a distribution map (see comment above), and one or more colour photographs for each species (regrettably without localities or date), but usually of spectacular quality, and it here that the book shines, and wins a place on many shelves.

But why, aside from this, would any Canadian naturalist want these books on their shelf? They do include all the species in eastern Canada, as all of these range north into this country from the United States. These accounts are of reference value for depictions of appearance (many species pictured are different from the Canadian variants) and natural history (contrast from more southern habitats) of these species in areas adjacent to Canada and beyond.

Attractive as it is, it is primarily an add-on for Canadian naturalists unless they are travelling south, and for practical purposes there are now many Canadian and adjacent state guides to reptiles and amphibians combined in single volumes that will be more useful references for identifying our herpetofauna.

FRANCIS R. COOK

Emeritus Curator and Researcher, Canadian Museum of Nature, P.O. Box 3443, Station D, Ottawa, Ontario K1P 6P4 Canada

BOTANY

Ginkgo in China

By Cao Fuliang. 2007. China Forestry Publishing House, Number 7, Liuhai Hutong, Denei Street, Xicheng District, Beijing, China. 300 pages. 98 CNY.

Ginkgo is a genus of highly unique plants with one extant species, *Ginkgo biloba*, which is a long-lived, stress-tolerant, disease-, pest-, and fire-resistant dioecious tree, referred to as a living fossil by Charles Darwin in 1859. The only surviving member of its family, Ginkgo leaf was first mentioned in Lan Mao's book *Pharmaceutical Natural History of Southern Yunnan* (1436) in the Ming dynasty of China. Engelbert Kaempfer (1651-1716), a German botanist, firstly gave a scientific description of this species in his book *Amoenitatum exoticarum* (1712), and formly gave it its name according to a phonetic pronunciation of a Chinese or Japanese word.

It was reported that fossils recognizably related to modern *Ginkgo biloba* date back to the Permian, some 270 million years ago. The genus diversified and spread throughout Laurasia during the middle Jurassic and Cretaceous, but became much rarer thereafter. At the end of the Pliocene, Ginkgo fossils disappeared from the fossil record everywhere apart from a small area of central China where the modern species survived. Chinese people, especially the monks in history formally, have long cultivated Ginkgo, thereby contributing to its survival as a species. All the present Ginkgo trees originated from China and were introduced into Europe in the 1700s, and then spread to other continents.

Ginkgo not only has scientific value in terms of research on its evolution and genetic tenacity, but also its medicinal and ornamental applications. Ginkgo has been used in medicinal botanicals in China for more than 2000 years. Nowadays, more and more medicinal functions of its leaves and seeds are being extensively revealed by scientists all over the world, with a focus on the standardized *Ginkgo biloba* extract (GBE) being prepared from the dried green leaves. At present, Ginkgo has become one of the most common trees along the sidewalks in many cities of the world due to its urban tolerant traits and the beautiful shape and colour.

China is the hometown of modern Ginkgo trees. The small-sized natural Ginkgo populations were extensively distributed over different geographical areas of China. The cultivation area of Ginkgo covers wider regions. The germplasm resource of Ginkgo is abundant. Ancient Chinese carried out preliminarily studies or observations on the trees. However, afterwards, there were not too many new studies in China due to the unstable or abnormal social and political situation. Since the 1980s, Chinese scientists have carried out a series of comprehensive studies on the trees. The book *Ginkgo in China* is a systematic summation of these studies. As well, the book collected and analysed other abundant information on the Ginkgo at home and abroad.

The book covers almost every aspect of the Ginkgo, such as its origin, evolution and taxonomy, history of cultivation and utilization, natural populations and cultivation areas, biological and ecological characteristics, cultivation techniques, exploitation and use of Ginkgo resources, genetics and breeding, and so on. Chapter one, is an outline of the Ginkgo's name, and its economic, ecological, social, cultural, scientific values, developmental status, and prospects; Chapter two covers the origin, evolution and taxonomy of the Ginkgo; Chapter three, the history of cultivation and utilization of the Ginkgo at home and abroad; Chapter four, the natural populations and cultivation regions of the Ginkgo; Chapter five: the biological characteristics of ginkgo; Chapter six, the cultivation techniques of ginkgo; Chapter seven, the comprehensive exploitation and utilization of Ginkgo resources; Chapter eight, the germplasm and breeding of the Ginkgo; Chapter nine, reputed varieties, strains or individuals of Ginkgo in China; Chapter 10, key areas of Ginkgo production; and Chapter 11, the development of the culture of the Ginkgo.

The book is well written with few errors, and can be easily understood by non-scientists. As a comprehensive book, it would be suitable for anyone who is engaged in various areas of research or application in relation to ginkgo. Hopefully, it would become a valuable reference for them.

Comprehensive Monograph of Contemporary Medicinal Plants (Volumes I-IV)

By Zhao Zhongzhen, Xiao Peigen. World Book Publishing House, Number 137, Chaonei Street, Beijing, China. 2008. 4 volumes: total 2180 pages. 368 CNY Cloth.

In a broader sense, the medicinal plants referred to are not only the so-called traditional medicinal plants used for prevention and treatment of human diseases, but also the plant resources used as nutrients, hobby materials, spices, coloring additives, pesticides and veterinary drugs and so on. The whole or parts of the medicinal plants can be used directly in treatment or as raw material in the pharmaceutical industry.

China is one of the countries with abundant resources of medicinal plants, and with the long history of use and cultivation. The discovery of medicinal plants was

the result of accumulation of experience and knowledge in the long-term production and life in ancient times. In China, literary records on medicinal plants might be traced to the Spring and Autumn Era (770 BC~221BC) or much earlier. Till the Ming Dynasty, the world wide famous comprehensive medicinal book *Compendium of Materia Medica* (Li Shizhen 1578), contained more than 1200 species of the medicinal plants.

Generally speaking, Chinese traditional medicine as a cultural treasure of China, together with Western medicine, plays an important role in human health care, and is the commonwealth of mankind. However, not all records in the traditional medicinal literatures were correct, and some of them were proved to be wrong or inaccurate with long-term clinical practices or scientific tests. Furthermore, some new pharmacological effects of these medicinal plants have been revealed, and some new medicinal plants have been gradually added to our knowledge. Therefore, the science of medicinal plants as an ancient and developing science needs systematic testing of the records in the traditional medicinal literature, and also needs a continual infusion of new knowledge or scientific findings. Actually modern medicine, or Western medicine, as a whole, has persistently absorbed a great deal of valuable experience and knowledge accumulated in the course of long-term clinical application and scientific research. However, the science of medicinal plants itself has been in the shade, and not summed up the progress of time.

The *Comprehensive Monograph of Contemporary Medicinal Plants* is divided into three parts and four volumes. The Chinese and English versions were published successively. The book collected information on more than 800 frequently used medicinal plant species from both China and abroad. Each entry of medicinal plant species includes Chinese, Latin and English names, main geographical distribution region, main morphological characteristics, medicinally effective parts, chemical composition, pharmacological effects and the progress in clinical applications. Abundant diagrams are used to supplement the explanations. The book adopted the definition of the medicinal plant species in broader sense, to include not only the traditional medicinal plant species being used for a long time both in China and abroad, but also the new products made from the medicinal plants, natural health plant products, natural plant cosmetics, natural plant pigment, and so on.

The book reflects the results of the authors' in-depth investigations on these medicinal plant species for many years. On the basis of systematic compilation and analysis of the illustrations of the efficacies of these medicinal plants in the voluminous traditional medicinal literatures, the book introduced the latest medical progress in plant biochemistry, pharmacological, toxicological and clinical research. For each medicinal plant species mentioned, the authors also give pertinent comments and suggestions on sustainable exploitation and utilization, as well as safety in clinical applications. All these might contribute greatly to the clarification of the mechanism of the role of the traditional medicine plants, to the modernization of the science of traditional medicinal plants, and to guidance for future clinical applications.

The book is well written with few errors. Abundant illustrations help readers understand the explanations. The book is suitable for professionals who engage in plant science, pharmaceutical research, production, development, testing as well as sales staff or other persons who are interested in these fields.

Book Review Editor's note: Continuing with our decision to investigate suitable websites and, if appropriate, include their reviews. I have written the following review. If others know of similar suitable sites and are moved to submit a review please contact me at r.john@rogers.com.

MushroomExpert.Com website

By Michael Kuo. 2008. http://www.mushroomexpert.com/index.html.

I recently wanted to identify a mushroom in my yard and, with help, thought it might be a Turkey Tail. On the web I found MushroomExpert.Com, a site developed by an Illinois English teacher and amateur mycologist, Michael Kuo. He is also the author of two conventional books; *Morels* (2005), and 100 *Edible Mushrooms* (2007) [University of Michigan Press]. By following Dr. Kuo's keys and his "Totally True Turkey Tail Test" I confirmed I had a totally true Turkey Tail.

I was very impressed by the individual pages on each species – the field guide section. This section currently covers 700+ mushroom species using identification keys. Each species has a web page with identification information, background material, habitat and some excellent photographs. Some of the photos are by the author, but there are many other contributors. The text is clear and easy to follow and shows a certain sense of humour. I smiled at phrases like "...let me say this as plainly as I can: *You are stupid if you eat this mushroom.*" It certainly gets to the point! There are web links to other mushroom sites, so you can see additional photos and read other versions of the species' characteristics [these were not as attractively displayed nor as well illustrated as Kuo's site].

There are three ways to search. You can step your way through the key system by clicking "Identification keys." For, say, *Boletus luridus* this is a four-step process and leads to Kuo's page [four photos]. For *Boletus flammans* you get moved to RogersMushroom with only one photo.

The second way to get to a species is to select a scientific name from a drop-down box. If you choose *Boletus bicolor* you get to Kuo's page. Oddly, if you go through the keys and decide this is your species there is no link to any further page.

The third method is to go to a search box and type in turkey tail and this will take you out to Google with a link back to MushroomExpert! This will also happen if you enter *Boletus flammans*, and the link will be the page with the link to RogersMushrooms. This all seems a little odd, but it does work. I think this is a reflection on the incomplete status of the site. The author, for example, states "We have not yet completed a key to North American polypores, but we have started the ball rolling with a key to the pale-fleshed, stemmed polypores".

I explored the site further and found it covers Collecting for Study, Making Spore Prints, Descriptions & Journals, Identifying Mushrooms, Determining Odor and Taste, Pronouncing Latin Names, Testing Chemical Reactions, Preserving Specimens, Using a Microscope, Mushroom Taxonomy, Introduction to Mushroom Photography, Digital Photography Tips, Scanning Mushrooms, Eating Wild Mushrooms, Mushroom Toxins, Meixner Test for Amatoxins.

I read a few of these sections and found them informative and remarkably well done. Where required they have excellent illustrations or photographs, including step-by-step sequences. If you intend not to heed the author's warning in paragraph two above, then read the section on toxins. Under Amatoxin he states , in part, "But the remission is a cruel hoax; in the meantime, the victim's liver and kidneys are being destroyed." A very unpleasant thought.

Kuo is currently writing, with Andrew Methven, *100 Cool Mushrooms*, [University of Michigan Press] and *Mushrooms of the Midwest* [University of Illinois Press.]

I have often been frustratingly confused by mushroom field guides. This is the first time I have actually enjoyed the process of resolving identification issues. This site is now in my list of "favourites" – a rare event as I only have 20 or so favourites.

Between Earth and Sky: Our Intimate Connections to Trees

By Nalini M. Nadkarni. 2008. University of California Press, 2120 Berkeley Way, Berkeley, California 94704-1012. 322 pages. 24.95 USD Cloth.

Nalini Nadkarni, forest ecologist and author of *Between Earth and Sky*, has written a natural and social history of trees, a tribute to the strong and influential global inhabitants she dearly loves. As she writes in the introduction to *Between Earth and Sky*, "I love trees: how they look, how they behave, how they smell and sound, and how I feel when I am around them." The first dedication of her book is to the "maple trees outside the front door, where this book began."

Nine chapters exploring the relationship between humans and trees cover topics as diverse as "what is a tree"; tree goods and services; trees as shelter and protection; trees and health and healing; trees in play and the human imagination; trees and the expression of time; trees as signs and symbols; trees in spirituality and education; and trees and mindfulness. Woven throughout the chapters is scientific fact, personal reflection and narrative, and a variety of visual material.

It is a compelling combination. I found the generous sprinkling of tree quotes, poems and other passages particularly intriguing. Passages from Shakespeare's *Othello*, Homer's *The Odyssey*, and a Woodie Guthrie song. Poems by Wendell Berry, William Blake, John Clare, E. E. Cummings, Jane Hirschfield, Pablo Neruda, Li Po, Rumi, Christina Georgina Rossetti, Percy Bysshe Shelley, and Rabindranath Tagore. Quotes by Hermann Hesse, Federico Garcia Lorca, and Antoine de Saint-Exupéry. One of my favourites is a line from *The Power of Myth* by Joseph Campbell and Bill Moyers: "God is the experience of looking at a tree and saying, 'Ah!'"

Creative writings aside, the book contains no shortage of scientific and other facts. I discovered "arboreal soil" situated on large branches in certain forests, spaces that epiphytes, insects, earthworms, and spiders call home. I learned about "witness trees," which bear permanent marks carved by settlers of forested lands to marks territorial boundaries. I was interested to read that the sacred architecture of Greek temples and Gothic cathedrals is thought to be inspired by sacred groves, and that Hindu and Buddhist temples are in fact associated with living trees.

Anyone who loves trees, who admires their steadfastness, who finds in their presence a certain peace and calm, will love this book. As Nadkarni writes in the introductory chapter, "When I place my own strong brown hand on the trunk of a tree, I feel connected to something that deserves my curiosity, care, and protection." Reading *Between Earth and Sky* makes you want to rush outside and follow her example.

Contributions to the History of Herpetology Volume 2

Edited by Kraig Adler. Society for the Study of Amphibians and Reptiles, Post Office Box 58517 Salt Lake City, Utah 84158-0517 USA. 396 pages. 65.00 USD Cloth.

This is volume 21 in the Society for the Study of Amphibians and Reptiles series *Contributions to Herpetology* begun in 1980. The first history contribution, number 5 in the series, was published in 1989 to commemorate the First World Congress of Herpetology held in Canterbury, England, that year. It contained biographies of 152 "Herpetologists of the Past" compiled by Alder using two criteria for inclusion: (1) significant contribution to herpetology and (2) deceased. Its scope was world-wide and included references for each biography, signatures, and 149 portraits. The book concludes with index to 2500 authors in taxonomic herpetology compiled by John S. Applegarth, and academic lineages of 1300 herpetologists by Robert Altig. It was 202 pages and priced at $20. It is now out of print but it has been put on the web for public access at www.ssarherps.org (click on "Publications"). The new volume extends the coverage of the first and has biographies of 285 additional Past Herpetologists (with signatures and 269 portraits) by Adler. Following sections are an index to 3604 taxonomic authors (again by Applegarth), and academic lineages of 3810 herpetologists (again authored by Altig). The price, in keeping with the times, has more than tripled. Like the first, this is also a commemorative volume, issued for the Society's 50th Anniversary Meeting, St. Louis, 2007.

The new biographies are comprised of both long-deceased herpetologists omitted in the earlier edition and recent ones who have died since the first was written. The accounts are grouped by 26 variable time periods from 1400-1500 to 1970-1990 with placement within each period based on when the person first became prominent in herpetology. Fortunately, there is an index (pages 259-273) covering both volumes that includes page numbers not only for the 437 subjects of individual biographies but also every mention of these and other herpetologists. The bibliographies in volume, 2 begin with Leoniceno (1428-1524) and conclude with Slowinski (1962-2001). The most recent additions are John L. Behler (1943-2006) and Margaret M. Stewart (1927-2006). Canadians, represented by E. B. S. Logier (1893-1979) in the initial volume, have one more entry in the second, Stanley W. Gorham (1917-1984). Stan's career was spent at the National Museum of Canada (now Canadian Museum of Nature) and the New Brunswick Museum and he authored, among other contributions, a checklist of amphibians of the world (1974). Its value is recognized here: "Even when a larger, more comprehensive checklist appeared in 1985, authored by a team of 59 specialists from 20 countries, Gorham's single-authored, simpler list still had the advantage of including synonyms and subspecies and remained a useful reference for many years". [See also 1991 tribute in *Canadian Field-Naturalist* 105: 592-596]. Adler continues to augment his files and there will be many more Canadians represented in a future volume 3 and beyond when the those so active from 1960 to the present are finally eligible for inclusion.

Interest in all corners of the history of biology has come of age and editor Adler is well suited to the task of documenting the herpetological research component. He is Professor of Biology and former Vice Provost for Life Sciences at Cornell University, Ithaca, New York. He has been President of the SSAR and was founding Secretary-General of the World Congress of Herpetology. He has published extensively on behaviour and systematics of amphibians and reptiles in scientific journals and books. He has been, and remains, a driving force in the hyperactive Society for the Study of Amphibians and Reptiles since its foetal days as the Ohio Herpetological Society and the publication of its first journal (1959-1966). He has promoted and edited both the Facsimile Reprints in Herpetology series (41 ranging from pamphlets to books) and the Contributions series as well as being a supporter of varied other publications of the Society: *The Catalogue of Amphibians and Reptiles* (840 accounts to date), *Herpetological Conservation* (2 volumes dealing with Canadian amphibians (1) 1997 and reptiles (2) 2007), *The Herpetological Review* (1967-, at volume 37 in 2006), *Journal of Herpetology* (1968-, at volume 40 in 2006) and *Herpetological Circulars* (1973-, 36 numbers to 2007).

Science and Conservation of Vernal Pools in Northeastern North America

Edited by Aram J.K. Calhoun and Phillip G. deMaynadier. 2008. CRC Press Boca Raton, 6000 Broken Sound Parkway, NW (Suite 300), Boca Raton, Florida 33487. 363 pages. 97.80 USD Cloth.

Some time ago the public began to notice that urban and private development had started to encroach upon lands which had traditionally been identified as wasteland, swamps and bogs. Habitat was being lost with the destruction of breeding grounds of birds, fish and many mammals to create shoreline, developed areas in subdivisions and agricultural lands where the previous condition of the land had been determined to be "too wet".

As we have spent research time, money and bureaucracy on the identification and preservation of wetlands, biologists have begun to see the further encroachment on lands which are seasonally flooded but do not have the distinction of being wetlands.

Pools of water and the retention of water in a protected setting often occurs in the springtime in many places in forested areas as well as shallow ditches both altered by humans or left by glaciation. With the presence of water, different habitats are created which provide breeding grounds for many invertebrates as well as amphibians, reptiles and birds, become present since the spring is breeding season and the above need habitat which will allow them to go through parts of their life cycles in standing water. Many plants are also associated with pools of water or the moist depressions which are left after the water evaporates. Many of us recognize these plants as common weeds but weeds provide seeds for food, shelter for nesting, and habitat for a variety of fauna to move and live beneath.

Conservation is one stated purpose of the book. Some states have already identified the shallow pools of water present in the spring, and other provinces and states could easily identify similar regions using the criteria outlined here. People who wish to live in country settings often have to alter the natural setting which they have selected in order to build upon it. Developers build according to formulae which sell houses, not rustic settings where the best interests of nature are preserved. Builders choose level versus low-lying ground which leads to bulldozing depressions into lawns and woodlots into open areas. Environmental laws now define the wetlands but the woodland depressions which form vernal pools have neither been identified nor are builders inclined to further limit the buildable space by looking for areas to preserve.

All researchers and professionals in the field who work in areas which are populated by vernal pools can benefit from this rich source. The available literature of flora, fauna, conservation and identification of vernal pools is shown for naturalists and conservationists alike. It has also built upon an earlier work by Elizabeth Colburn, *Vernal Pools: Natural History and Conservation* (Colburn 2004) and borrows heavily from her further research.

This book is a valuable resource in the identification and ecology of seasonal pools which support many amphibians, insects and invertebrates. Reptiles, birds and mammals are also occasional visitors and sometimes breeders. Human building pressures, pesticides, and conservation opportunities are all parts of the study forming the most comprehensive work I have seen on this topic to date. I was only able to read this book slowly because it contains so much research but found myself going back to sections for reference around related topics. It is well researched, carefully prepared and a valuable resource for conservationists.

Amazing Animal Journeys

By Liam O'Donnell. 2008. Tourmaline Editions Inc./DK Publishing Canada. 48 pages. 4.99.CAD Paper.

Snow Dogs! Racers of the North

By Ian Whitelaw. 2008. Tourmaline Editions Inc./DK Publishing Canada, 662 King Street West, Suite 304, Toronto, Ontario, M5V 1M7. 48 pages. 4.99 CAD Paper.

Amazing Animal Journeys and *Snow Dogs! Racers of the North,* both by Canadian writers, are books about animals and travel. *Amazing Animal Journeys*, rated at DK Publishing's Level 3-Reading Alone, is the story of four long-distance wildlife migrations. *Snow Dogs! Racers of the North,* rated at Level 4-Proficient Readers, is about dogs and people travelling together in the north.

Of the two books, *Snow Dogs! Racers of the North* is the most coherent, mainly because it focuses on a single story line: dog sledding. The book is divided into 10 chapters covering topics that include the history of dog sledding, human-dog teamwork, descriptions of high-profile sled-dog races, and profiles of sled-dog racers. The information provided is comprehensive and interesting. The sentence structure is dynamic, flowing, and appropriate to the reading level. And the illustrations, mainly photographs, as well as maps of dog-sled race routes, are plentiful and colourful.

All things considered, *Snow Dogs! Racers of the North* is an interesting, well-written book. My only complaint is with the title, which suggests a book about sled dogs. Yet the content of the book concentrates on sled-dog racing, races, and mushers. While dogs are depicted in most of the photographs, and mentioned on every page, the spotlight is not shone on them very often, and then only briefly.

Two of the book's 48 pages deal with breeds of sled dogs. One paragraph is dedicated to the roles played by dogs positioned at different points along the gangline. One photograph and three sentences portray Balto, the famous lead dog who guided the sled in the last leg of the heroic journey that inspired Alaska's renowned Iditarod Sled Dog Race. Oh yes, the name of another lead dog involved in that journey, Togo, was also mentioned.

The book's title led me to hope for at least one chapter on the various breeds of sled dog developed in differ-

ent parts of the world. Another chapter portraying famous sled dogs, past and present, would have been fascinating, and would have helped round out the book and make it truer to its title. And I would have liked to see more information about the qualities sought for dogs playing different roles on a sled-dog team. The dogs, who work so hard, and who give so much to the sport – without whom the sport would not, in fact, be possible – deserve as much.

The focus of *Amazing Animal Journeys* is definitely on animals. And the stories it tells – about Barren-ground Caribou, Monarch Butterfly, Gray Whale and Snow Goose migrations – are indeed amazing. While the book offers lots of terrific information and colourful illustrations, mainly photographs, it tries, in my opinion, to do too much.

Covering four complex wildlife migrations in 48 pages is itself an amazing feat. To do so successfully would have required either telling fewer migration stories more fully, or telling the same number of stories more simply. The author, unfortunately, tried to take the middle road, and the result is stories that jump around a little too much for smooth reading, and that don't provide enough links between details to make the information flow nicely. That said, the sentence structure is appropriate to the reading level, and the stories are certainly interesting.

Both books, however, left me wanting to know more. And that, perhaps, is not a bad thing.

The Vermont Reptile and Amphibian Atlas Project Publishes the First Vermont Amphibian Posters

The Vermont Reptile and Amphibian Atlas Project has produced two informational posters on the amphibians of Vermont. Amphibians Part 1 contains the frogs of Vermont and Amphibians Part 2 contains the salamanders of Vermont. Photographs of all Vermont amphibians are included on the posters along with the latest available (2005) distribution maps, identification information, and the basic natural history of each species. These posters reflect the most reliable and current information available on Vermont amphibians. Each color poster is approximately 23" by 16" and is printed on durable, glossy, heavyweight paper with non-fading inks. Posters cost $9.43 each ($10 with VT sales tax) with a $3 shipping charge. In 2006, two Vermont reptile posters were printed and all four posters can be seen at the Atlas website http://community.middlebury.edu/~herpatlas/index.html. All proceeds from the sale of the posters will help fund the Vermont Reptile and Amphibian Atlas project.

The Vermont Reptile and Amphibian Atlas Project is an effort begun in 1994 by the Vermont Reptile and Amphibian Scientific Advisory Group to the Endangered Species committee. The atlas project initially began as an effort to gather data for use by this volunteer advisory group in order to make informed recommendations regarding the appropriate status and conservation of reptiles and amphibians in Vermont. Since then, the goals have widened to incorporate public education, encourage citizen involvement, and promote conservation. The Atlas Project is coordinated by Jim Andrews, a research herpetologist at Middlebury College. The ultimate goal of the Atlas is to gather and disseminate data on reptiles and amphibians in Vermont in a way that involves and informs Vermont individuals and organization so that they will become more informed and effective stewards of wildlife habitat. Since the Atlas began in 1994, over 3,000 individuals, fifteen private organizations, and many government employees and agencies have provided over 60 000 records of local reptiles and amphibians. With the help of these volunteers and a few part-time staff members, the atlas continues to collect information and broaden the knowledge base regarding the natural history, distribution, and effective conservation of Vermont's reptiles and amphibians.

Any resident or visitor can contribute valuable distribution information simply by reporting what they saw, when they saw it, and where it was. Reports can be forwarded by mail, phone, or better yet, through the use of online reporting system at the website http://community.middlebury.edu/~herpatlas/index.html. Photographs are particularly helpful but not necessary. With a good description, sketch, or photograph, they can figure out what species you have observed and enter it into their database. The data help them generate accurate maps of the in-state distribution of Vermont's native herptofauna.

Maps at their website show clearly the towns and species most in need of additional survey work. Some of the towns most in need of additional reports include Lunenburg, Lyndon, Andover, Baltimore, Burke, Danville, Granby, Irasburg, Rutland, Cabot, Derby, Elmore, Warner's Grant, Avery's Gore, and Pittsfield. Cities most in need of additional surveys include St. Albans, Barre, Newport, and Vergennes. Species most in need of additional reports include all reptiles but particularly snakes other than Gartersnake and all turtles. However, gaps exist in the distribution maps for even some common species and in some towns that have been surveyed more thoroughly.

Additional information on the posters, how to contribute to the survey effort, and resources on identification and natural history of these species groups can be found at http://community.middlebury.edu/~herpatlas.

For more information please contact James Andrews, Vermont Reptile and Amphibian Atlas, Sunderland 114, Middlebury College, Middlebury, Vermont 05753 jandrews@middlebury.edu.

The Ottawa Field-Naturalists' Club Awards for 2006

Irwin M. Brodo, Christine Hanrahan, Diane Lepage, and Eleanor Zurbrigg

On April 28, 2007, members and friends of the Ottawa Field-Naturalists' Club gathered at the Club's Annual Soirée at St. Basil's Church in Ottawa, and once again, awards were given to members, and one non-member, who distinguished themselves by accomplishments in the field of natural history and conservation, or by extraordinary activity within the Club. Careful observation of plants and animals, political savvy, selfless service, and teaching skills are all in evidence among this year's winners. The following citations for those who received an award were read to the members and guests assembled for the event.

Annie Bélaire – Member of the Year

The OFNC's Member of the Year award recognizes the club member judged to have contributed the most to the club during the previous year. Annie Bélaire is this year's Member of the Year for her dedicated, creative and innovative involvement with the Macoun Club, as well as her work as a volunteer at the Fletcher Wildlife Garden.

Annie started working with the Macoun Field Club four years ago, in the fall of 2003. Annie attends every meeting and field trip as a knowledgeable leader, always ready to answer children's questions and enrich their experience with her special knowledge. For example, when the group found the fresh remains of a big coyote-killed deer in Stony Swamp, she eagerly seized the skull and pointed out to all who were gathered around, "You can tell this was still a young deer, because the teeth are still sharp and the dentine and enamel are of equal thickness!" Understanding that part of Stony Swamp is the Club's Study Area, she undertook a resurvey of Eastern Hemlock trees and found that their population has declined severely over the past 15 years, owing to a special fondness of porcupines and deer for their foliage. She then shared her findings with the children at a Macoun Club meeting, and wrote up her report for the Club's *Little Bear* magazine.

In the face of declining membership in the Macoun Field Club in recent years, it became clear that one of the major problems is "getting the word out," i.e., publicity. To help the Macoun Club reach families with young children, Annie designed a vibrantly coloured new brochure and a poster, which have become significant parts of its publicity efforts.

Aside from her energetic efforts with the Macoun Club, Annie participates as a willing volunteer at the Fletcher Wildlife Garden as part of the Friday morning crew working in the Backyard Garden and Butterfly Garden, and also serving on the FWG committee. In addition, Annie has done translations for our brochures and other bilingual Club documents, and she has put a lot of time into organizing and data-basing the library.

Annie Bélaire is clearly well qualified to be our Member of the Year for 2006.

Christina Lewis – George McGee Service Award

The OFNC George McGee Service Award is given in recognition of a member who has contributed significantly to the smooth running of the Club over several years.

Since joining the OFNC in 1995, Chris Lewis has been an exceptionally busy and productive member of the club. A long-time member of the Birds Committee, Chris has served as recording secretary since 2001, a position she continues to fill. Many club members will recognize Chris as one of the stalwarts of the Seedathon team who not only organizes, but participates in this important event to raise money for the purchase of seeds for all the OFNC bird feeders in the region.

Chris is the recorder and reporter for the OFNC's Bird Status line, a position she has held since 2001. She is responsible for making sure the data are logged, recorded, and ultimately submitted to ONTBIRDS, the provincial listserv for bird observations. This is no small task and is vitally important if we are to have reliable data on bird occurrences in this region.

In 2003, Chris joined the OFNC's Bird Records Subcommittee, which is responsible for reviewing all rare bird reports from the region. A very keen and knowledgeable birder, Chris has also written numerous rare bird reports since 1995. In addition, she contributes significantly to the Bird Records Subcommittee database.

Chris is also responsible for many of the regular quarterly bird summaries in *Trail & Landscape*. She has also authored or co-authored many other articles for *T&L*, most recently an excellent report on the first confirmed nesting of the Double-crested Cormorant in Ottawa. Chris authored the significant species summaries for the Ottawa area for the *Birder's Journal* (2001-2004), and for the American Birding Association's *North American Birds* (2001 to the present).

With Bob Bracken, she has co-authored several articles promoting Ottawa area bird-watching for "OFO News", the newsletter of the Ontario Field Ornithologists.

When the Ontario Field Ornithologists held their annual convention in Ottawa in September 2006, Chris very capably assisted not only with promotion of field trips for this event, but helped to lead several very successful trips.

While many people may connect Chris with birds, there are many more who know her as an expert on odonates – dragonflies and damselflies, and on Lepidoptera. Over the last decade she has led or co-led numerous walks for the OFNC on birds, butterflies, dragonflies (the Morris Island dragon walks are very popular), fish and general natural history.

Her interest in, and knowledge of, odonates has led her to publish some important articles on dragonflies and damselflies of the Ottawa area, and submit an astonishing 2,000+ records of odonates for the Ottawa area, together with Bob Bracken, to the Ontario Odonata Summaries. She and Bob received the 2001 Anne Hanes Natural History award for this work.

These are remarkable contributions, both in terms of service to the club and to the furthering of our knowledge of natural history in this area. For all of these reasons, the OFNC is pleased to give the 2006 Service Award to Christina Lewis.

Madeline Kallio – Conservation Award (Non-Member)

The OFNC Conservation Award – Non-Member is given in recognition of an outstanding contribution by a non-member in the cause of natural history conservation in the Ottawa Valley, with particular emphasis on activities within the Ottawa District.

For nine years, Madeline Kallio has been the driving force behind the National Capital Region Wildlife Festival. Through its Wildlife Awareness event, library programs, public forums, guided nature walks and more, the festival has, for many years, introduced the general public to natural history and the concept of conservation.

While the festival appears to run effortlessly, in fact, a tremendous amount of organization and year-round planning is required. Madeline Kallio chairs the festival committee which meets approximately 11 times a year, produces the minutes, and attends to the thousand and one details that arise. She is the liaison with the Billings Bridge Shopping Centre (where the wildlife awareness event takes place), drawing up detailed floor plans, and ensuring that everything needed to make this particular event run smoothly is taken care of. She is also the link with all the exhibitors, contacting them each year, determining their requirements, making sure they have the right location for their exhibit, etc. She staffs the Wildlife Festival booth for the entire three days and is always available should other exhibitors need assistance. Coordinating an event of this magnitude and ensuring that it runs smoothly requires skill, good organizational abilities and huge time commitments.

Madeline also writes all the grant proposals and constantly seeks new ways to fund this event. In addition, she writes, produces and prints the festival's events brochure. A few years ago, she came up with the brilliant idea of developing a map of greenspaces in eastern Ontario where people can explore nature. Called "On the Trail of Mother Nature" this large, full-colour map, prepared, researched, and primarily designed by Madeline, has been a huge success with several updates and thousands of copies distributed.

Madeline is full of ideas for making the festival ever more interesting. One example is the library program series, which is so popular that presenters from previous years contact Madeline to make sure they are included in the current line-up, while libraries begin asking for information well in advance of the festival itself. She encouraged the idea of a public forum (now in its fifth year), has been instrumental in organizing the festival's Environmental Awards ceremony, and probably has a hundred other ideas just waiting to burst forth! Endlessly resourceful, energetic, and tireless, Madeline is always willing to step in and pick up where needed. On top of all this, she is always a calming, cheerful presence, seemingly unflappable, and without a doubt is the glue that holds the festival together!

Long before she was the festival's Coordinator, Madeline was a member of the festival committee, joining in 1990. When a coordinator was needed, Madeline stepped in and has not looked back.

You might think that the festival was enough to keep Madeline occupied full-time. This would be true for most people, but Madeline is involved in a number of other activities, including volunteering for the Kanata Canada Day program. She is also an accomplished writer who has written and published many articles and brochures. Chances are, you have seen her writing. If you have picked up brochures on Lanark County Maple Byway Tours, or browsed the 'Coffee Companion' newsletter in a Kanata coffee house, read magazines such as Fifty-Five Plus or Due West, you've seen her work.

Back in 1985, Madeline set up Ottawa Valley Field Trips, to introduce young and old to the joys of the natural world. She developed hands-on environmental programs for schools, organized workshops on natural history themes for the school boards, and worked extensively on nature interpretation programs with the National Capital Commission, Scouts Canada, Girl Guides, the Home School Association and other learning and public groups. The company also developed "backroads tours", which explored interesting villages and natural areas on the backroads of Eastern Ontario, as well as longer trips in Ontario, Quebec and the U.S.

The OFNC is proud to recognize Madeline Kallio for her outstanding efforts on behalf of nature and conservation in the Ottawa region, and in particular for her work with the National Capital Region Wildlife Festival.

Frank Pope – Conservation Award (Member)

The Conservation Award for Members is presented in recognition of an outstanding contribution by a member of the OFNC in the cause of natural history conservation in the Ottawa Valley, with particular emphasis on activities within the Ottawa District. Frank Pope is chosen as the recipient for the 2006 award in recognition his skillful leadership of the Alfred Bog Committee for over 20 years, which in 2006 achieved its goal of protection for the Alfred Bog for generations to come. Alfred Bog, lying 75 kilometres east of Ottawa, is one of the great conservation success stories of the past two decades. It took long years of hard work by local groups and all levels of government to finally save this vulnerable wetland from peat extraction, logging and drainage.

Frank Pope's involvement in the Alfred Bog conservation effort began in earnest in the early 1980s. A large part of the bog had been re-zoned to Agriculture, and an appeal to the Ontario Municipal Board seeking to keep the zoning as Conservation had failed. Not willing to accept defeat, Frank Pope, with Charles Sauriol of the OFNC, created the Alfred Bog Committee in 1985 to bring together interested folks and strengthen the bog protection effort. (At the time, Frank could not have known that it would take over 20 years to achieve success!) Frank chaired the Alfred Bog Committee in its ongoing save-the-bog campaign for the ensuing 20+ years, a long, drawn-out struggle that, against the odds, achieved its goal.

In this exhausting battle, Frank's commitment never wavered in the face of setbacks. His efforts spanned a range of activities — making credible presentations at Ontario Municipal Board hearings, tribunals, advocating legislative change at the provincial level (for example, to enable municipalities to control peat extraction activities), commenting on official plans and by-laws, working with major NGOs (NCC) in land acquisition efforts, fund-raising, and negotiating with diverse groups to name but a few.

Under Frank's leadership, the Alfred Bog Committee watched for acquisition opportunities within the bog, and initiated such activities as the preparation of a management plan, a major report on the plants, animals and hydrology of the bog, contacts with other land holders in the bog, the preparation of educational brochures and articles and field trips into the bog. Funding was obtained and a 1000 ft. boardwalk was constructed in the bog, because the impressive natural features of the bog made it a popular destination for naturalists and outdoor lovers, whereas walking in the bog is destructive to bog flora and hazardous to walkers.

In the years leading up to 2004, the combined conservation work of non-governmental groups and the several levels of government intensified. The Nature Conservancy of Canada purchased a total of 2800 hectares of the bog, and Ontario Parks now holds title to this property, to be managed as a provincial nature reserve. Peat harvesting within the bog was banned when the Prescott-Russell County Council passed the Alfred Bog Protection By-Law. In addition, peat-mining operations that border the bog and still pose a threat to its integrity are now required to operate according to rules designed to minimize this threat. All appeals of the county official plan pertaining to the Bog are withdrawn and the years-long mediation of the Ontario Municipal Board terminated. The Bog now has an official boundary and wetland designation. Quite a success story!

With this conservation award, the OFNC is recognizing Frank Pope's unflagging commitment, leadership and final success in the effort to gain environmental protection for Alfred Bog. Congratulations, Frank!

Linda Jeays – Anne Hanes Natural History Award

This award is given in recognition of a member who, through independent study or investigation, has made a worthwhile contribution to our knowledge, understanding and appreciation of the natural history of the Ottawa Valley.

Linda Jeays, an enthusiastic birder and longtime member of OFNC, began to study butterflies as a Millennium project. Her first identification was a Black Swallowtail flushed while watching waterfowl at Richmond lagoons. She jotted down a description, later referred to a field guide, and suddenly had a new natural history interest.

Linda is a former English teacher with an inclination towards note-taking. In her first summer studying Lepidoptera she began to make detailed documentation on every butterfly she encountered except where numbers made this impractical. She also keeps data on topics such as flight season, habitat, nectaring plants, road-kill and garden species.

At the end of the 2001 season, Linda learned that her sightings of Eastern Tailed Blue and Common Buckeye were very rare in the Ottawa area. Encouraged by Ross Layberry to write up her observations for *Trail & Landscape* and to check the locations again the following year, her detailed notes soon became valuable. In 2002, Linda again saw Buckeye briefly, but her real work began when she netted Eastern Tailed Blue within 10 feet of a previous year's site. In the very few records available, no one else had reported the butterfly in a repeat location.

What if Eastern Tailed Blue had overwintered? Linda began spending many hours each week netting, measuring and individually marking the Blues. Each year she recorded her findings in T&L, accumulating proof of overwintering. She has now established the presence of this species at one site near Richmond for six consecutive years. The culmination of Linda's work came in the summer of 2006 when she spent over 250 hours

in the field documenting the population explosion and widespread dispersal of Eastern Tailed Blue. She herself tallied 30 locations and 160 individuals. Another 25 sites and 170 Blues were reported by independent contributors to the Annual Eastern Tailed Blue Roundup that Linda conducts.

Linda Jeays has written feature articles, essays, humour, book reviews and autobiographical material for newspapers such as the *Ottawa Citizen* and the *National Post*. She has many magazine credits and has worked on assignment for the Canada Safety Council. Linda wrote her first short item for *T&L* in 1975. In 1977 she called then-editor Anne Hanes about submitting a piece of free verse. Anne said that unfortunately *T&L* did not use poetry, but she would still like to read the poem. "Metamorphosis" was printed in January 1978, the first of Linda's 35 poems in the club magazine

Anne Hanes would surely have been pleased that her early encouragement of the creative expression of Linda's nature observations has developed into meticulous factual documentation of Eastern Tailed Blue and a worthwhile contribution to the knowledge and understanding of this butterfly in the Ottawa Valley.

For her outstanding contribution to our further knowledge of the Eastern Tailed Blue in the Ottawa Region, we are very pleased to present Linda Jeays with the Anne Hanes Natural History Award for 2006.

Isabelle Nichol – Mary Stuart Education Award

The Mary Stuart Education Award was established to recognize members, non-members or organizations, for their outstanding achievements in the field of natural history education in the Ottawa Region. The OFNC is pleased to give the award for 2006 to Isabelle Nicol.

Isabelle has a great affinity for teaching natural history. She is both knowledgeable and enthusiastic and conveys this interest to the many lucky people who have been in her classroom or participated in her many field trips. Isabelle was a former employee of the NCC but, before she left that job, she was actively working on this, her second career that she has pursued so successfully for over 15 years.

Isabelle is a freelance teacher of natural history who is invited back year after year in several local schools because of her natural ability to teach and because of her careful planning of various natural history modules that complement the subjects covered in the grade school curriculum. These include modules on habitats, plants, hibernation in winter, migration, spring ephemerals and active winter wildlife. She works closely with the teachers to tailor her teaching to fit the interests and abilities of the students at hand.

Recently Isabelle has branched out and now also teaches natural history to various senior citizen groups and garden clubs. Over these many years Isabelle has also been a much sought after field trip leader for our Club, where participants have come to appreciate her quiet style and originality. We have a first rate natural history teacher in our midst and it is time that she be appropriately honoured.
